IARI

Journal of the Royal Society of Arts.

No. 3,705. VOL. LXXII.

FRIDAY, NOVEMBER 23, 1923.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2).

ONE-HUNDRED-AND-SEVENTIETH SESSION, 1923-1924.

PATRON—HIS MAJESTY THE KING.

VICE-PATRON—H.R.H. THE PRINCE OF WALES.

COUNCIL.

H.R.H. THE DUKE OF CONNAUGHT AND STRATHEARN, K.G., President of the Society.

LORD ASKWITH, K.C.B., K.C. D.C.L., *Chairman of the Council and a Vice-Pres. of the Society.*

SIR CHARLES STUART BAYLEY, G.C.I.E., K.C.S.I., *Vice-Pres.*
LORD BEARSTED, *Vice-Pres.*
LORD BLYTH, *Treasurer.*
A. CHASTON CHAPMAN, F.R.S.
SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., *Vice-Pres.*
CHARLES FREDERICK CROSS, F.R.S.
MARQUESS CURZON OF KEDLESTON, K.G., P.C., G.C.S.I., G.C.I.E, *Vice-Pres.*
SIR WILLIAM HENRY DAVISON, K.B.E., D.L.
SIR EDWARD DAVSON.
EDWARD DENT, M.A., *Vice-Pres.*
EARL OF DURHAM, K.G., P.C., G.C.V.O., *Vice-Pres.*
PETER MACINTYRE EVANS, M.A., LL.D., *Vice-Pres.*
SIR ROBERT ABBOTT HADFIELD, Bt., D.Sc., F.R.S.
REAR-ADMIRAL JAMES DE COURCY HAMILTON, M.V.O.
SIR THOMAS HOLLAND, K.C.S.I., K.C.I.E., D.Sc., F.R.S.
LORD INCHCAPE, G.C.M.G., K.C.S.I., K.C.I.E., *Vice-Pres.*
SIR HERBERT JACKSON, K.B.E., F.R.S., *Vice-Pres.*
MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E.
LT.-COL. SIR ARTHUR H. MACMAHON, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I., *Vice-Pres.*
SIR PHILIP MAGNUS, Bt.
SENATOR GUGLIELMO MARCONI, G.C.V.O., LL.D., D.Sc., *Vice-Pres.*
WILLIAM HENRY MAW, LL.D., M.Inst.C.E., *Treasurer.*
LORD MONTAGU OF BEAULIEU, K.C.I.E., C.S.I., *Vice-Pres.*
HON. SIR CHARLES ALGERNON PARSONS, K.C.B., LL.D., D.Sc., F.R.S., *Vice-Pres.*
ERNEST H. POOLEY, M.A., LL.B.
JOHN SLATER, F.R.I.B.A., *Vice-Pres.*
SIR GEORGE SUTTON, Bt.
JAMES SWINBURNE, F.R.S., *Vice-Pres.*
ALAN A. CAMPBELL SWINTON, F.R.S., *Vice-Pres.*
CARMICHAEL THOMAS, *Vice-Pres.*
J. AUGUSTUS VOELCKER, M.A., PH.D., *Vice-Pres.*
SIR FRANK WARNER, K.B.E.
SIR PHILIP WATTS, K.C.B., LL.D., F.R.S., *Vice-Pres.*
SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., *Vice-Pres.*
SIR HENRY TRUEMAN WOOD, M.A., *Vice-Pres.*
SIR ALFRED YARROW, Bt., M.Inst.C.E., *Vice-Pres.*

SECRETARY—G. K. MENZIES, M.A.

Secretary, Dominions and Colonies and Indian Sections—SAMUEL DIGBY, C.I.E.
Accountant and Examinations Officer—J. H. BUCHANAN.
Chief Clerk—GEORGE DAVENPORT.
Auditors—MESSRS. KNOX, CROPPER & Co.

NOTICES.

NEXT WEEK.

TUESDAY, NOVEMBER 27th, at 4.30 p.m. (Dominions and Colonies Section.) VISCOUNT BURNHAM, C.H., LL.D., D.Litt., M.A., "The West Indies." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

WEDNESDAY, NOVEMBER 28th, at 8 p.m. (Ordinary Meeting.) SIR HENRY JOHN GAUVAIN, M.A., M.D., M.Ch., Medical Superintendent of the Lord Mayor Treloar Cripples' Hospital, "The Effect of Sun, Sea and Open-air in the Treatment of Disease." LORD DAWSON of PENN, G.C.V.O., K.C.M.G., M.D., F.R.C.P., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

A meeting of the Council was held on Monday, November 12th; Present:—

Lord Askwith, K.C.B., K.C., D.C.L. (in the Chair); Lord Blyth; Sir William Henry Davison, K.B.E., D.L.; Mr. Edward Dent, M.A.; Sir Robert Hadfield, Bt., D.Sc., D.Met., F.R.S.; Rear-Admiral James de Courcy Hamilton, M.V.O.; Sir Thomas Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S.; Major Sir Humphrey Leggett, D.S.O., R.E.; Sir Philip Magnus, Bt.; Dr. William Henry Maw, M.Inst.C.E.; Mr. John Slater, F.R.I.B.A.; Sir George Sutton, Bt.; Mr. James Swinburne, F.R.S.; Mr. Alan A. Campbell Swinton, F.R.S.; Mr. Carmichael Thomas; and Dr. J. Augustus Voelcker, M.A.; with Mr. G. K Menzies, M.A. (Secretary of the Society), and

Mr. S. Digby, C.I.E. (Secretary of the Dominions and Colonies and Indian Sections).

On the nomination of H.R.H. The Duke of Connaught and Strathearn, President of the Society, Sir Dugald Clerk, K.B.E., D.Sc., LL.D., F.R.S., was elected a Vice-President of the Society and a Member of the Council.

Arrangements for papers to be read after Christmas were further considered.

Other formal business was transacted.

SWINEY PRIZE.

Attention is drawn to the fact that the last day for receiving entries for the Swiney Prize is November 30th, 1923.

The prize is a cup, value £100, and money to the same amount, and is offered on this occasion for the best published work on general Jurisprudence.

Any person desiring to submit a work in competition, or to recommend any work for the consideration of the judges, should do so by letter, addressed to the Secretary of the Society, by the date mentioned above.

Notice of the competition was printed in the *Journal* of June 1st, 1923.

SECOND ORDINARY MEETING.

WEDNESDAY, NOVEMBER 14th, 1923; MR. ALAN A. CAMPBELL SWINTON, F.R.S., Ex-Chairman of the Council, in the Chair.

The following candidates were proposed for election as Fellows of the Society :—

Burnham, Walter Witt, London.
Jack, James, New Cumnoch, Ayrshire.
Jacques, Gilbert J.P., Ontario, Canada.
Markgraf, Miss Agnes, The Hague, Netherlands.
Peterson, President Elmer George, Ph.D., A.M., B.S., Logan, Utah, U.S.A.

A paper on "Téléphotographie, Télautographie, Télévision (avec Expériences et Projections)" was read by M. EDOUARD BELIN.

The paper and discussion will be published in a subsequent number of the *Journal.*

REPRINT OF HOWARD LECTURES.

The Howard Lectures on "The Development of the Steam Turbine" by STANLEY S. COOK, B.A., M.I.N.A., M.I.M., have been reprinted from the *Journal*, and the pamphlet (price 2*s.*) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2.

PROCEEDINGS OF THE SOCIETY.

◆

FIRST ORDINARY MEETING.

WEDNESDAY, NOVEMBER 7TH, 1923.

LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

The Chairman delivered the following Address :

EXHIBITIONS.

By LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council.

With the coming of the great British Empire Exhibition at Wembley in 1924, it may be well to reflect for some brief time on the subject of Exhibitions, and even to consider some aspects of the possible bearing of such an Exhibition as this on Science, Art and Industry. The importance of the subject is further enhanced when it is remembered that an Empire Economic Conference is even now being held between the principal representatives of all parts of the British Empire, and that the coming Exhibition is specially to illustrate the products of the British Empire in Science, Art and Industry.

It seems to be particularly apposite that in an inaugural address your Chairman should consider the subject, although, owing to the numerous reports, lectures and articles which have emerged from a succession of exhibitions, much that could be said must necessarily be repetition of ideas and statements already published. Repetition is at least surrounded by many advantages which I need not now discuss, but the apposite character of the subject arises from the fact that, as Sir Henry Trueman Wood remarks in his admirable History of the Royal Society of Arts, "it may certainly be claimed for the Society that it initiated the idea of Industrial as well as Fine Art Exhibitions." He adds that "there seems no doubt that the earliest industrial Exhibition of which there is any record, was the Exhibition, held by the Society of Arts in 1761, of Agricultural and other Machines, for which the Society had offered prizes."

Sir Henry mentions Exhibition after Exhibition supported by the Royal Society of Arts, culminating in the great Exhibition of 1851, and the various efforts which since that day have been made in this and other countries, until Exhibitions have become a natural feature called for at intervals in all parts of the world. No longer are they viewed with the surprise evoked by the small but brilliant display given in 1851, that great work for which the Royal Society of Arts was so largely responsible, and with which the name of Prince Albert, the father of our President, will ever be identified. May our Royal Family ever continue to maintain that honourable tradition! A concise historical account of these and subsequent exhibitions can be read in Sir Henry's book, which every member of the Royal Society of Arts might well purchase, and it may be mentioned that in 1851 Prince Albert suggested that a series of lectures should be given at some of the Society's meetings "on the probable bearing of the Exhibition on the various branches of Science, Art and Industry," a proposal which led to 24 lectures by eminent lecturers and may be a precedent for persuading speakers of the present day to give us in this hall the advantage of their study of the Exhibition.

A list of exhibitions from 1851 down to 1907, prepared by Sir Henry Trueman Wood, was published in the *Journal* of November 8th, 1907 (Vol. 55, No. 2868.) The list is intended to include, besides the genuine International Exhibitions, all industrial and technical exhibitions of an important character. The list, for the 56 years between 1851 and 1907, takes note of 374 exhibitions, of which 71, or more than one-fifth, were held in London. They were of very varying character, but if numbers only are taken, the rest of the United Kingdom and France come next with 40 each, the United States held 24, and Australasia 22. I think later officers of the Society might well prepare a subsequent list and keep the record up-to-date.

Making, therefore, no apology for considering the subject before this Society, I would initially emphasize the fact that exhibitions have been marked by varied and continuous growth. During the course of the 150 years new theories and aims have necessarily been developed. Unless there had been elasticity and adaptability, it is plain that so world-wide a system would not have come to stay, and in point of fact, the theory has extended, as it were, both vertically and horizontally. No particular laws seem to have governed this extension. In truth, growth has been very haphazard. Given a show, such as that of agricultural and other machines in 1761, the horizontal extension has enlarged the number and types of agricultural machines exhibited, and added to the exhibition of agricultural machines every conceivable kind of business connected with them, widening the band to include earths, animals and vegetables. Given, again, a show such as that of 1851, the vertical extension has embraced more and more countries, more and more products, and more and more additions and side shows only remotely connected with the main principle. The growth of the vertical extension has been apt to become so great that it has occurred to promoters that sectional exhibitions must be held, such as for Fisheries and Inventions, embracing the conception that by taking different sections the general exhibition could be broken up, and that exhibitions could be held every year, thus, in a manner, again returning to the horizontal method. The haphazard growth of the system brought its own condemnation. Enough interest could not be aroused in each special section, enough time was not given to the preparation and adequate presentment of the sections, and the public became frankly bored with a similar yearly exhibition of side shows, of which the novelty had worn off, with some industry attached to them in which they took minor interest, and in which the scientists and the industry itself found themselves neither properly prepared nor in any better position than practical relegation into a side show which gave a name to the exhibition for the current year.

If distrust and doubt began to be prevalent in this country, they were not destroyed here, and indeed spread to other countries, when calls were made for exhibitions in Paris in 1900, St. Louis in 1904, and again in Brussels in 1908. The speed with which exhibitions followed one another, the heavy expense and difficulty of organisation inseparable from exhibitions such as that of St. Louis, and in many cases the doubtful advantages to manufacturers seemed to be onerous burdens. It is to the credit of this country that it initiated an attempt to bring some order into the system, not only in Great Britain, but, after the Brussels Exhibition, into the arrangements which could be made with other countries as to the times and scope of Exhibitions. So far as this country was concerned, the initiation arose from the importance of enquiring into the expenditure of public money. A Committee was appointed "to enquire and report as to the nature and extent of the benefit accruing to British Arts, Industries and Trade from the participation of this country in Great International Exhibitions ; whether the results have been such as to warrant His Majesty's Government in giving financial support to similar exhibitions in future, and, if so, what steps, if any, are desirable in order to secure the maximum advantage from any public money expended on this object."

The Committee, in their report, illustrated the haphazard methods which had been customary. They remarked that "the participation of this country in great international exhibitions has never been governed by any continuous or clearly defined principles." They also stated : "One of the most striking facts revealed by an examination of the Official Reports of the Royal Commissions, which have acted on behalf of this country in the past, is the absence of continuity by which their work has been characterised. The participation of Great Britain in each successive exhibition would appear to have been created as if it were an entirely new problem, unconnected with those that had gone before, and little, if any, attempt seems to have been made to apply to one Exhibition the lessons derived from another." My study of the Reports leads me to the conclusion that the Committee correctly stated the position, although Cole and Owen had done as much work as pioneers could well do.

The effect of this system was reflected in the result, which was thus described : "There appears to be little doubt that, taken as a whole, the British sections at all the more recent exhibitions have not afforded an adequate and satisfactory representation of the nation's industries. With the exception of the Arts Exhibits, which at recent exhibitions have undoubtedly attained a high degree of excellence, the goods exhibited in the British sections would appear to have been of very uneven quality. Many of the more important industries of this country, if represented at all, were represented by firms of minor importance. The exhibits of many of these firms were often creditable to themselves, but it cannot be said that they were representative of the best productions of the country, or that they compared as a whole favourably with the exhibits of other countries." The last sentence appears to me to be too drastic a criticism.

Any praise in this summing up was distinctly faint, and certainly did not say much in favour of British power of organization.

In consequence of the Committee's report, an Exhibition Department under the Board of Trade, attached to the Commercial Department, of which I was then the head, was established here, and after the Brussels Exhibition that Department was able to take steps for better International arrangements in regard to the holding of exhibitions. It owed, perhaps, its influence to the manner in which the British section at Brussels was worked, and, after a disastrous fire, restored speedily and well.

The whole of that Exhibition would have come to grief if this country had failed to exhibit, and one of the best sections had been non-existent. It is to the credit of the Government of the day, and the efforts of Lord Lytton, that £60,000 was at once given to resuscitate the section, and to the credit of our industries that manufacturers, including Sir Frank Warner, a member of your Council, worked hard to produce a fine section, and, incidentally, to earn much gratitude from Belgium.

So successful was the exhibition, that other countries, of which I think Brazil was the most prominent, wanted exhibitions of similar character. Brazil held an Exhibition on the Centenary of Independence, which was largely supported for political reasons, but the experience of the cost to governments and to manufacturers, and also of the time and trouble involved, had been a valuable lesson. Our country took the lead in an endeavour to put on some reasonable basis, in collaboration with other countries, when and where exhibitions were to be held ; and what exhibitions should receive other support beyond the competition of such manufacturers as desired to participate. It is too much to force manufacturers continuously to send their goods to the ends of the earth, to any and every exhibition which may be announced, however badly the preparatory work has been done, and however little interest or result may be acquired in the country where the exhibition is held.

So far as international exhibitions are concerned, the efforts of promoters require strict examination, and casual faddists or profitmongers should be discounted. Anyone can exercise ingenuity in suggesting exhibitions or hope to gain notoriety or profit by their promotion, but these efforts ought, by reasonable arrangement, to be sifted, and these "highwaymen" treated at their proper worth.

The result of our endeavours ended in a Convention signed at Berlin in December 1912 by 15 European countries and Japan, but never ratified. Its main objects were "to limit the number of great international exhibitions and to establish a uniform code of regulations with a view to reforming their organization and administration." It was laid down that at least three years must intervene between great international exhibitions, and useful rules on official patronage, uniform regulations, fire, juries, and the suppression of abuses were proposed. At some future date ratification of this Convention, with such amendments as later practice can suggest, may be desirable.

The study of the work of this Department and of the literature of exhibitions, leads me to the conclusion that in the carriage of exhibitions at least three main principles ought always to be borne in mind, the principles of careful preparation, of efficient organization, and of sympathetic management both before and after the exhibition.

The principle of careful preparation would include the abolition of the haphazard growth of which I have spoken. It would include consideration of the scope of the exhibition, the object, aim, and value; and, if the scope of an exhibition, whether international or local, has been properly considered and defined, and a competent authority has decided that an exhibition is desirable and ought to be held, either in any particular place, or for any particular sections of industry, the succeeding step is that there should be ample time for preparation and plenty of spade-work given to the foundations.

Many an exhibition has gone to grief for lack of due perception of the importance of time and spade-work. Exhibitions cannot be improvised and brought into being by saying that they should be held. The history of exhibitions is strewn with accounts of the losses and disappointments caused by the lack of that very obvious principle, the necessity of preparation; and, owing to the lack of machinery for determining whether the participation of this country was desirable or not, decisions to take part in an exhibition have been often taken by our Governments at too late a date to permit of proper preparation of the British sections. Too many masters, lack of organization, slackness or delay on the part of sections of industry or representatives of particular countries, are only a few of the many factors which may lead to trouble. Proud should be the managers of any exhibition who may be able to say on the day of opening: "There is a completed work to which we have nothing further to add."

The second principle, akin to early preparation, is that of efficient organization. Each country or each trade may require organization of its own, but there must necessarily be some central authority to hurry up the sluggard and, as far as possible, to prevent schemes or plans alien to the exhibition as a whole. Such organization ought to be settled from the very first, or else there are sure to be misunderstandings or even disaster. We in this country, in our usual English way, seem to repose confidence in Committees. The coming Exhibition started with an Executive Council, Committees of Management, Finance, Accounts, etc., and General Manager, whose place has now been taken by an Administration Committee, commonly called "The Big Five," under whom work a Director of United Kingdom Exhibits, a Controller of General Services, a Controller of Stadium and Entertainments, and a Finance Manager. Our Committees are not confined to a central committee, but extend to sub or minor advisory committees relating to each trade and branch of a trade. These committees expand still further—to conferences and to congresses. Thus it is stated that, for the coming Exhibition, "the Textile Institute of Manchester, in co-operation with the leading textile federations and associations, is organizing an Empire Textile Conference. A general committee has been formed composed of leading men in the industry. The object of the conference will be to promote the commercial, technical and scientific knowledge of the textile industry, to bring about a closer relationship with various parts of the Empire, and to discuss problems of production, distribution and consumption, with a view to co-operation where possible."

"The Convention of the Associated Advertising Clubs of the World, which is being organized by the Thirty Club of London, will make Wembley the focus of all the principal advertising organisations of the world. The Institution of Mining and Metallurgy and the Decimal Association have also arranged to hold conferences, while among the subjects still under consideration are migration, education, child welfare, labour, public health and retail distribution." The biggest conference will be the World Power Conference.

"Apart altogether from open conferences of this kind, many industrial and other organizations have already arranged to hold their annual congresses at Wembley, where they will have the benefit of the experience and counsel of overseas visitors, and a committee has been established to settle about these and other congresses." And then there are the juries, but of these more anon.

Other countries have had systems different from our own. France, where exhibitions were so fostered by the first Napoleon, and where, since 1851, exhibitions have been so remarkable, has a system which has been thus described: "The principal feature of the French system is that practically the whole of the work of organization is performed by a Committee of the Exhibitors themselves . . . nominally under the control of a Commissioner General appointed by the Ministry of Commerce. All the active work of preliminary investigation and organizing the exhibits is undertaken by the Committee, and practically the whole of the cost of the French section, with the exception of exhibits of an unremunerative nature, such as Education, Art, Social Economy and the like, is borne by them." The Committee is controlled by a Council elected by themselves every three years, and there are Executive Committees for (1) Propaganda, (2) Enquiry and Preliminary Organization, (3) Entertainments and Receptions, and (4) Accounts and Publications. By this system continuity has been obtained, there has been self-government by industry, and the general excellence of French exhibits is a strong testimony to their power of organization.

In Germany before the War, the system was entirely different. The organization, preparation, and supervision of the German sections was done by a single official, nominated by the Chancellor and appointed by the Emperor. This Commissioner was responsible for large sums paid by the Government, and his power was practically supreme. Any member who saw the large isolated German section at Brussels will realise that by this means unity of scheme was obtained, that heavy expenditure must have been incurred, and that a peculiar effort seemed to have been made to produce an effect and to attract the public by an unusual, if not bizarre, display.

We in this country have, owing to lack of continuity, had no entirely fixed system. In the more important exhibitions, though not in the coming Exhibition, the British section has usually been in the hands of a Royal Commission, but the Committee of 1906 reported that "the evidence obtainable with regard to the organization of the British sections at most of the exhibitions is for the most part of a very vague and uncertain nature. The information contained in the official reports is often incomplete, and it is difficult to form from them any clear idea as to the manner in which the grants were expended and the exhibits organized. . . . As a general rule, it may be said that the assistance afforded by the Government to British exhibitors has been confined to the provision of an organization which would enable them to display their goods if they desired to do so at their own expense. With but very few exceptions, the whole cost of the preparation, transport, insurance, installation, and decoration of the exhibits appears to have been borne by the exhibitors themselves, and few inducements were offered by the Organizing Body with a view to securing the co-operation of firms who were unwilling to exhibit for their own personal profit."

The result of this sytem was scathingly criticized in the report of His Majesty's Commissioners after the Paris International Exhibition of 1900. They made remarks like these: "In the British section every exhibitor used his space in accordance with his own fancy and showed what he pleased." The appearance of "the undignified collection of show cases of different sizes and designs which filled the British space was little less than painful." "As a rule, a British manufacturer will only exhibit if he can select his own goods, and display them in his own way, and in his own show case. He is impatient of advice; he will not submit to dictation; he will not share a show case with others; nor will he join with others to adopt a uniform plan of arrangement."

The result of this extreme individualistic attitude, though it has some merits in principle, prevented any really comprehensive display of the principal manufacturers of the country. There was delay before Royal Commissioners, if any, were appointed. Other countries got the best sites. Insufficient space was obtained. The best firms often stood aside and failed to exhibit. There was competition for insurances, freight, and labour, with undue expenditure. One exhibit might be completed, while others all round it were unfinished, empty, or disfiguring; and visitors will not face sawdust.

An attempt was made at St. Louis with some success in the direction of collective exhibits, and the advice of the Paris Commissioners that the best hope of the future lay in well-organized collective combination, coupled with symmetrical arrangement, has borne more or less fruit. Those Commissioners, however, repeated the warning, "It is essential that the preparation of such exhibits should be begun in ample time."

It remains to be seen whether the "Big Five" will have successfully organized the coming Exhibition, but from the notices of their efforts, it would appear that a distinct advance, in spite of the very many diverse lines, old and new, upon which they have to work, will be shown in 1924. No prejudicial opinion should be based upon the incidents of one football match; and indeed, the experience then gained may have been very serviceable. If their success transcends any previous experience since 1851, lessons of value may be obtained which should indicate the best methods of preserving continuity in the future. I trust that they may not be lost sight of.

The third principle to which I alluded was sympathetic management. There must be executive officers, and in 1906 it was reported that "the same lack of continuity that has characterised the appointment of Royal Commissions in the past is also noticeable in the selection of executive officers." The Committee said the Secretary of the Royal Commission, when established for an Exhibition, had not only done much of the active work of organization, but in most cases had acted as the Commissioner General of the Exhibition itself, and had usually taken charge of the work of installation, decoration and general management of the British section. It is obvious that work of this character requires first class men, involving, as it does, not only energy, application, training, and experience, but also great sympathy and power of dealing with men. In the past Sir Henry Cole was a very dominating personality, and at a later date Sir P. Cunliffe Owen was well known for his energy and skill. But in 1906, it was said that though it was "mainly upon this one officer that the success or failure of the national display as a whole depends, it is not a little surprising to find that in no two of the more important exhibitions in which this country has taken place since 1878, has the post of Secretary and Commissioner-General been filled by the same man." Sir P. Cunliffe Owen, secretary at Paris and Vienna, may possibly be an exception to this statement.

That the work of management is no sinecure, may be aptly illustrated by the extract I have already quoted from the report of the Paris Commissioners in 1900, on the extreme individuality of the British exhibitor. In 1908 Mr. U. F. Wintour took up the office of manager and did remarkably well in the Brussels Exhibition. He continued his services as a Civil servant on behalf of the Exhibitions Department of the Board of Trade at other exhibitions, worked in all the initial stages of the present Exhibition as a general Manager, and, I understand, receives payment in an advisory capacity at the present time. The work, however, is too much for one man, though the division of authority is not an easy problem to solve. In our usual way we now have a Committee, or Board, aided by other Committees, amongst whose members it is pleasant to know that Colonel H. W. G. Cole, grandson of Sir Henry Cole, who won fame in 1851 and 1862, is a Chief officer of the British Government Pavilion and in charge of some remarkable exhibits. It is to be hoped that the general experience may lead to a report on the best method of dealing with the difficulties of the future, and laying down right lines for a developing institution, and for continuity, even if great international, or Empire, exhibitions do not often recur, and give place to the less expensive exhibitions of special products or trades.

Among other general questions which have been always debated, may be mentioned the subject of juries, and the question of the value of exhibitions. As to juries, it is difficult to dispense with them, and still more difficult to ensure that their awards should not be too numerous or too open to criticism. Allegations of intrigue and favouritism are easy to make, and difficult to controvert. Continuity, expert knowledge, sufficient numbers, methods of appointment and selection, are factors which have to be considered. The work of judging requires care and knowledge. The Berlin Convention laid down some useful rules, suggesting divisions into grades and restriction of numbers, on the principle that juries would have to continue. On the whole, I think it may be said that British jurors have been remarkable by the care which they have exercised. It is perhaps because we are here so accustomed to the jury system. At any rate, it is a traditional system in this country, and though it has from time to time been criticized as unsatisfactory, it has been so generally used ever since 1851, and is in such general demand for exhibitions of all kinds, such as shows of the Royal Horticultural Society, that its continuance almost appears to be certain in many exhibitions, though wholesale and indiscriminate distribution of awards may be curtailed. The methods of judging and the employment of right men, are, of course, details in which improvement by experience can from time to time be made. It may be that for the avoidance of rivalry between mother-country and dominions, and between the overseas countries themselves, in this particular exhibition at Wembley, so impracticably vast for correct grading in terms of excellence and efficiency of products, awards and the rivalry of awards, and the employment of juries, can be reduced or even eliminated. The proposal has been made and has received wide acceptance. If that course should be taken the effect would be interesting to judge and might indicate variant experiments in the future.

On the question of the value of exhibitions much might be said. It is difficult to estimate the value to the country as a whole, or to the manufacturers and exhibitors in general or in particular. For the country as a whole a good exhibition can scarcely be without considerable value. Education and knowledge are increased. Invention and the application of science to industry are stimulated. A great deal of innocent amusement is given. There is a certain binding link which results from the common purpose. To manufacturers and exhibitors in general I am inclined to think the value is also great. Advertisement at the present day improves by leaps and bounds, and an exhibition is a vehicle by which ready and great advertisement may often be obtained. New and unknown firms have an opportunity of coming into notice. Novelties and articles for which there is little demand become known, and may quickly appeal to the consuming public. There is, for instance, the well-known story of Bass's beer, and how the firm made their fortune by supplying that beverage in the thirsty summer of 1851, and never looked back since. And, lastly, not only are the Art sections generally the most attractive parts of the Exhibition, but have generally proved of value to artists themselves.

As regards particular firms or individuals, the evidence must necessarily be mixed. There can be no statistics of benefit. Firms are not likely to disclose, even if they can gauge, the actual results direct or indirect, which they have obtained. They will judge exhibitions by what they think is the result. In some cases they will grumble at the trouble, the expense, and the time. They will allege disclosure of inventions, the unfair copying of their exhibits, and even the copying of a trade in which they hoped to have a monopoly.

In the Report of the Commissioners for the International Exhibitions at Brussels, Rome and Turin, in 1910 and 1911, it is remarked that "participation in an International Exhibition, like other forms of advertisements, may lead to results which it is very difficult, if not impossible, to trace, and in considering benefits derived from an exhibit it should, therefore, be borne in mind that, although no actual increase in business may be traceable, abstention from the Exhibition might have resulted in loss of prestige and consequent diminution of sales."

Perhaps the most important point for any firm or individual to consider is to have a capable agent, so that the exhibitor may not have to complain that success has not attended efforts in comparison with others owing to faults which may be due to bad organization, bad salesmen, or bad methods of showing exhibits.

These general remarks only indicate some factors in a large subject, and some of the principles and questions which I believe are vital to it. A present question, the British Empire Exhibition, is immediately before us, a mere stepping stone, I think, in the developing future, but a stepping stone of great importance, from which many lessons may have to be deduced. Not the least of these lessons is the fact that this is the third great exhibition held in this country after the exhibition of 1851 and the comparatively unsuccessful exhibition of 1862; and that our attention is continually directed back to the exhibition of 1851, of which the material results now visible are the building called the Crystal Palace, the Victoria and Albert Museum, and the Science and Art Department, with many minor derivatives such as the recent exhibition of "Industrial Art of To-day," by the British Institute of Industrial Art, at the Victoria and Albert Museum. That Exhibition of 1851 marked an epoch. Will this? The first impression coming to my mind in the consideration of 1851 is the vast gulf between that epoch and this present year, particularly in the aspirations and ideas of the world at that time, and in the developments of art, science and commerce, which have, in fact, occurred. The second is but an idle speculation, whether in the year 2000 the same result will have occurred, and all our aspirations and ideas and all the developments of art, science and commerce, marching with the increased velocity of accumulating force, will have taken a course utterly different from any present anticipations, but proceeding, as they have done since 1851, in a manner scarcely noticed by the overlapping generations of men.

There are but few men now who can throw their minds back to 1851, but without appeal to their memories, it will be sufficient for the purpose of indicating the gulf to mention a very few documentary proofs. The most salient example I can find is contained in the changes seen, and considerably aided by, the late Admiral of the Fleet, Sir Arthur Wilson, whose life has recently been published. That officer fought in the Crimean War in 1855, in the Egyptian War at El Teb, and only retired from work for the Navy in the summer of 1918, very nearly the period of time to which I have alluded. Between the Crimean and the Egyptian Wars alone he witnessed or worked at the invention and use of the torpedo, the invention of the submarine mine, the use of long distance signalling, the advance of scientific gunnery, and the revolution in ship construction between the old three-decker "Algiers," and the battleship "Inflexible," a ship now thrown into the scrapheap, in comparison with "Nelson" and "Rodney" and other famous monsters of the sea. Since the Egyptian War up to 1918, the developments are too numerous to describe. No dream of the air, or wireless communications, or the spread of the turbine engine or the development of oil, or the submarine ship, engaged the practical mind of Sir Arthur Wilson in the Egyptian War, yet he lived to see them all commencing their careers.

Compare this with the considered opinion of Captain Washington, R.N., F.R.S., given before the Society on March 3rd, 1852, when he stated the following appreciation on the progress of Naval Architecture, and on the exhibits: "In the Mercantile Navy the magnificent ship, the Great Britain, constructed by the eminent builder, Patterson, of Bristol, claims the first place, both as an iron vessel and as a screw-propelled steamer. This noble ship, 317 feet long, with engines of 1,200 horse power, has repeatedly made the voyage across the Atlantic; and now that she has been repaired and strengthened, is again open to start on a similar voyage, in which it may be hoped she may meet with the success that her spirited owners deserve. In a country like England, where iron is so abundant, cheap and well adapted to various purposes, it was natural to use it instead of wood, and it has been largely substituted for timber in building ships. The advantages of iron vessels, when carefully built, consist, generally, in their durability, strength, capacity for stowage, economy and salubrity; but iron does not appear to be applicable for ships-of-war."

Verily a certain play, which many of you have seen, was well entitled "Milestones"; but though the gallant captain may have been too dogmatic about the use of iron and its derivatives, he at least had the spiritual sense of hope, and the practical sense of seeing the value of that Chinese proverb which Sir Robert Hadfield has so often reiterated: "He who owns the iron of the world rules the world," a proverb not unworthy of consideration at the present moment.

The lectures on the Exhibition of 1851, from which I have quoted, were inaugurated by the celebrated Master of Trinity, Dr. Whewell, in an address sprinkled with Latin quotations and allusions to Aristotle and Sophocles, Longinus and Homer, Ulysses and Calypso. Some of the aspirations of the period are still before us, some of them have been fulfilled, some have signally failed. I will only call attention to a few types. Professor Solly, on vegetable substances, remarks: "With continued care and attention, and by persevering in the introduction of improved methods, a complete change will in time be effected in the deficiencies of East Indian cotton, so that ere long any quantity of sound and good cotton may be imported for the use of manufacturers, from British India. The cotton at present imported from the British colonies does not quite amount to a million pounds yearly. It is, however, rapidly increasing. The cotton of British Guiana is excellent, and some of that lately sent over from South Africa is also very promising. Considerable progress is also being made in the cultivation of cotton in the northern parts of Africa. . . . Mr. Mercer's new process for modifying its chemical and physical properties seems likely to produce very important alterations in the manufacture of cotton generally."

Mr. James Glaisher, F.R.S., announced the following conviction: "The high interest that science in its highest applications and developments of power commanded from the Illustrious Designer of the Exhibition leads to the reasonable expectation that more encouragement will be held out to those who are capable of adding to the number of truths on which such applications are founded, and in this view I am supported by a brother juror, Sir David Brewster, who writes: 'I am persuaded that the Exhibition will exercise the most salutary influence on this subject, in so far as it will turn the attention of the influential classes of society to the vast national importance of encouraging science and the arts by placing men who advance them in a better position than they have hitherto occupied in this country.'" Has that persuasion come true?

Another writer was too enthusiastic over a difficulty still with us when in writing of certain bricks he says that this simple means will place at the command of the working man "a certain degree almost of luxury, which tends to refine the mind, and substitutes a comfortable home for a miserable and barely efficient shelter from the elements, the ambitious and wise design of those who have of late actively promoted the improvement of the dwellings of the working classes."

The dominating Mr. Henry Cole was more within the mark when he said: "The beginning of the reform of our Patent Laws or laws for the recognition of the rights of intellectual labour, which I foresee may have great international results on industry, is due to the Exhibition." He was quite right. The Revised Patent Laws did result from the Exhibition of 1851, and I trust very sincerely that a subject in which I have taken great interest, a British Empire Patent, will be the result of the present Economic Conference and the Exhibition of 1924. The recent resolution of the Economic Conference seems only to go half-way towards that desirable result.

Following upon the Exhibition of 1851 there were very remarkable developments on which, though not due to the Exhibition, I think it may be said the Exhibition had weighty influence. At the very end of 1863, in a report on the Exhibition of 1862, the statement is made that "Never before in the history of man have the products of the mineral kingdom exercised within a brief period so momentous an influence on the fortunes of nations as that which in the last fourteen years has riveted the attention of the whole civilized world. If we look back only to the date of our first Universal Exhibition, we find that a series of changes has been brought about which, but for the potency of the effect produced by mineral substances, would have required decades of years, if not centuries, to accomplish. Coal, the great basis of manufacture and locomotion, has been extracted on a scale never before contemplated, and sought for and found in new countries and under new conditions with something like equal strides; it has also been made to yield a variety of products brought with unexampled rapidity into the applications of daily life. Iron and steel have been manufactured in masses and applied to purposes equally unknown in former times. Metals scarcely known except by name in 1851 have become the subjects of operations of commercial importance. And, lastly, the succession of gold discoveries in so many widely separated and enormous regions has led to the exploration and settlement of vast tracts by myriads of men, with a facility which was impossible before the extended use of iron and coal had smoothed the way for so gigantic an emigration."

Is it too much to prophecy that the principle involved in this statement will be the principle which the coming Exhibition may best keep in view and may best assist, in ways and means of which many were unknown and undreamed of in 1863, namely, the abolition of distance?

No longer is the world divided into small states, with relatively little interest in their external dominions, but vast empires and great countries have competed for a hold over the more sparsely peopled lands or less energetic peoples, and divided the world—the British, French, American and Russian countries, and in lesser degree Germany, Italy and Holland. Western civilization has indeed seized the reins of the world, and with the complexity of life and trade which makes it almost impossible for countries to be self-sufficient, it has become a necessity to organize and utilize the less developed portions of the earth. Further, the more highly industrialized a country may become, the more dependant must it be on supplies brought from all parts of the world. The abolition of distance becomes a necessity of existence.

We are not saying now "What has the world got to offer?" but "What has the British Empire got to offer, not to the United Kingdom only, but by every country within the British Empire to every other country within the British Empire?"

In their summings up the lecturers of 1852 dilate on the extension of trade, the new processes, the application of science to industry, and the coming future developments; but the products of the British dominions are scarcely mentioned. In Mr. John Hollingshead's Concise History of the International Exhibition of 1862, he says that "In 1851 the colonies were, as a whole, almost unrepresented. The notice given was too short; the undertaking was hurried; the project was quite new, and not thoroughly understood; and, moreover, most of the colonies were scarcely in a position to go to much expense for contributions. The East India Company, however, made a noble display and some few of the British colonies a respectable appearance."

It was not till the Indian and Colonial Exhibition, and the Jubilee pageants of 1887 and 1897, that the nation began to awake, largely by these shows, to a better knowledge of the import of the British Empire; and how much has happened since to bring that knowledge home by practical facts? It is but fitting that some stock should be taken and education spread more widely than ever; to make us realize that the British Empire is not that which the German Treitschke called it, "A thing which is wholly a sham," but a living and growing entity, bound together in a manner different from any other known to history.

The aspirations and thought of that Empire may not be crystallized in any code. Some might characterise them as vague and indeterminate, but yet the immediate course of movement seems in some measure to be indicated by present waves of thought, and by the practical application of those thoughts, and it is within our province to consider whether they are reflected in this Exhibition. If I may select only three of the present movements, now being rapidly developed, they would be these: First, the extension of speedy communication; second, the extension of research into the history of man, of the world and of the universe; third, the determination to search for and reduce and cure disease among men, animals and plants. There might be added other movements, such as various applications of machinery, but these three great movements are engrossing great attention, and seem to progress, despite the hindrance of political and racial quarrels, despite the squabbles between capital and labour and social changes, with a certainty and speed which ignore the littleness of hindrance and convince mankind even against their will. And yet they may be changed, just as the ideas of 1851 were changed, by new discoveries and new ideals of which at present we have no ken.

Apart from new material, however, these three movements are quite capable of affecting or settling great matters, provided man pursues them with courage and judgment. The peopling of the world, the education and feeding of the world, are involved in the speedy communication, in such items as the turbine engine, broadcasting, telephony and wireless. Secondly, the theory of Einstein, the marvellous work of Rutherford, the digging of Evans, Carnarvon, and Howard Carter, and the American research in Mongolian fossils are but illustrations of the movement for research into the history of man, the world, and the universe. And thirdly, as to disease, nothing has been more remarkable than the range of interest taken in this subject, from cancer to the boll weevil, by scientists and the public at large. Almost as if answering to the demand the discoveries of science have been manifold; and if the mere means of support were more forthcoming, those discoveries might be multiplied with increasing speed, but while we endow unemployment with hundreds of thousands of pounds, we cut off subventions for the bare maintenance of the institutes of science as if they were superfluous.

Of these three great movements to which I have alluded, apart from any surprises, the coming Exhibition will be a great exemplar, bringing them into better knowledge amongst the mass of the people, and also amongst the people of all our dominions. It has well been said by an American paper (The Christian Science Monitor): "This Exhibition may be regarded as a co-operative effort towards developing a greater commonwealth founded upon that confidence and goodwill which is manifesting itself among the British people in every part of the world." At the present time that is a great truth, and the pursuit of knowledge in these three movements must add to the co-operation, to the confidence and goodwill, thus alluded to.

All of them receive undoubted attention, and some in a manner quite new, I think, to exhibitions of this character. Thus there is to be a World Power conference, to consider the national and international adjustment of power. The discussions are billed to be on Power Resources, Power Development, Transport by Land, Air and Water, Power Applications in Agriculture, Industry and General Utility, and Economic and Financial Power. Following the example of Brussels, there is a section to illustrate the dangers of Tropical diseases and their prevention and cure, as well as demonstrations of plant and animal diseases. In special sections and in the general "lay-out" of the Exhibition these great movements are remarkably included in every one of the main sections, with their groups and classes. These sections are to be housed in buildings designed with harmonious intent, many of which may be deemed to be a triumph of architectural skill and taste, while the exhibits will be arranged in a manner from which the old show cases will be strangely absent. In the great Stadium pageants, more educative and striking than any that art has yet attempted, will show the evolution of British history. Films will preserve those pageants and, circulated through the land, bring home to every school more knowledge than teachers could ever give by word of mouth. The Stadium too will be used to illustrate the effects of massed music, in addition to many athletic contests, and on Empire Day for a solemn service, when King and peoples will together join in united hymn and prayer.

In most of the accounts of the Exhibition I have seen a great amount of space taken up in speaking of its size. Thus: "The Overseas Empire occupied only 60,000 sq. ft. at the Paris Exhibition of 1900, and even at the White City in 1908 no more than 160,000 sq. ft. At the British Empire Exhibition from 600,000 to 700,000 sq. ft. of space will have to be provided." Or, again: "Originally 120 acres, the site of the Exhibition has been extended to meet growing demands, and is now over 200 acres." Or, again: "The size of the Exhibition may be imagined when we say that the frontage of the two buildings which will house the Industrial Exhibits of the United Kingdom alone could extend from Charing Cross Railway Bridge to Westminster Bridge. Those erected by the Dominions, India and the Colonies will be on a similar magnificent scale." etc., etc., etc. Those of you who visit the Exhibition will doubtless find it as large as you desire it to be, without caring much as to the exact number of square feet which it contains, or the cost, but will pay more attention to the mass effect, and to the ease with which you will find the exhibits or departments which each person desires to see. Both of these results are claimed for the Exhibition.

The amusement part of the undertaking is also said to be going to be of a higher standard of excellence than has been attained at any previous exhibition, with musical and dramatic performances and, as it is curtly put, "the usual attractions appealing to all classes and all ages . . . in abundance." Not only that, but sport and athletic contests will draw tens of thousands whom "the usual attractions" might not influence. They, as well as the majority of visitors, will have to be supplied with food and drinks, so that catering, with all its ramifications, will be a business taxing ingenuity and skilled organization. Sir P. Cunliffe Owen started upon a line of attracting the public which he would scarcely recognize, and that one branch alone vividly illustrates the immense strides which have been made in the development and growth of Exhibitions.

Lastly, it is of no use talking about an exhibition unless you can get there. Most exhibitions have left much to seek in this respect. This one will provide a very crucial test, and be an object lesson, it may be hoped, in what organization can effect. Apart from motors, tramways and buses, and provincial traffic, it is said that there are 126 stations in the London area from which the Exhibition may be reached in 18 minutes, and 120 City and suburban stations from which it can be reached without changing. The motor park seems rather small, but there are new main roads for motor traffic. If the immense numbers of people leaving in the final rush hours can be daily handled without hitch, a remarkable feat will have been accomplished. I hope there will be places at each station for lost children, and possibly for apprehended pickpockets!

In addition, within the Exhibition itself, internal railways and electric trolleys are to ease the disturbing factor of fatigue of the body, and a system of flood lighting in various tones of colour is designed to mitigate the fatigue of the eye. How such changes will affect complexions and dress remains to be seen. Light by day and light by night, light such as no other exhibition has ever had, coupled with a demonstration of "things electric" in every sense, should indeed make it, in the modest words of the *Electrical Review*, "an occasion to convince the world of many things."

One could dilate at infinite length on the details and other qualities, not to mention quantities, of this vast display, and doubtless that task will be gradually done, and, in fact must be done, by book, magazine and newspaper, for the continued education of our far-flung peoples. This Exhibition is not the last word. It is a stepping stone in the long line of previous shows, evolved from the changes in the world, the progress of commerce, science and art, and especially the united effort in a common cause of all the great nations and countries who will be here represented for comparison or emulation in one small space (if one may apologize to the eulogists of size), and who had never been joined before 1914 in one united concrete enterprise. It will be a milestone in the road of progress. Its effects may be manifold in many startling ways, concretely in science, industry and art, and mentally in impressions and knowledge. Those impressions will be as varied as the nations, races and minds of the millions by whom it will be visited, but to few will be denied all imaginative capacity, and it may be that at least there is one type of impression which may be common to all those many millions—possibility and hope. In that event the spirit of the Exhibition—the real thing that matters—will not vanish away, and be lost to memory, but will live and grow through the coming centuries, even when the passing troubles of the present day have become only incidents in an historical past.

The Chairman then presented the medals for Papers and Lectures given during the last session, as follows:—

Papers read at the Ordinary Meetings:—

OVERINGENIEUR DR. SIGURD SMITH (Charlottenlund, Denmark), "The Action of the Beater in Paper Making, with special reference to the Theory of the Fibrage and its application to Old and New Problems of Beater Design."

MAJOR W. S. TUCKER, R.E., D.Sc., "The Hot Wire Microphone and its Applications to Problems of Sound."

EDWARD PERCY STEBBING, M.A., F.L.S., Professor of Forestry, University of Edinburgh, "The Forests of North Russia and their Economic Importance."

SIR WILLIAM MACKENZIE, K.B.E., K.C., "Industrial Arbitration."

Papers read in the Indian Section:—

THE EARL OF RONALDSHAY, G.C.I.E., late Governor of Bengal, "A Clash of Ideals as a Source of Indian Unrest."

GEOFFREY ROTHE CLARKE, C.S.I., O.B.E., I.C.S., Director-General, Posts and Telegraphs, India, "Postal and Telegraph Work in India."

Papers read at Joint Meetings of the Indian and Dominions and Colonies Sections:—

LIEUT.-COLONEL SIR LEONARD ROGERS, C.I.E., F.R.S., F.R.C.P., F.R.C.S., Physician and Lecturer, London School of Tropical Medicine, "Recent Advances towards the Solution of the Leprosy Problem."

SIR RICHARD A. S. REDMAYNE, K.C.B., M.Sc., M.Inst.C.E., M.I.M.E., F.G.S., "A Review of the Base Metal Industry, with Special Reference to the Resources of the British Empire."

DISCUSSION.

Mr. Alan A. Campbell Swinton, F.R.S., said he was sure the audience would not wish to disperse without according a very hearty vote of thanks to Lord Askwith for his admirable and eloquent address. Lord Askwith had touched on many subjects, and the address must have taken a great amount of time and trouble to prepare. It was a very complete paper dealing with all aspects of the subject. He would only speak with regard to two of them. Lord Askwith had said, quoting somebody else, that the ordinary manufacturer looked upon Exhibitions not altogether with pleasure. Among other things, he (the speaker) happened to be a manufacturer—at least he was a director of several large manufacturing concerns—and the attitude of manufacturers towards Exhibitions was, he thought, as follows. Probably new undertakings welcomed Exhibitions because they were a method by which those undertakings became known by exhibiting at them, but old-established manufacturers were inclined to look upon Exhibitions more or less with dislike. They, however, recognised it was necessary that they should exhibit at them, as they could not afford to be left out.

The other matter to which he would like to refer was the great want in London of a suitable building for Exhibitions—not big Exhibitions such as that which was going to be held next year at Wembley, but ordinary kinds of Exhibitions like the Motor Show. Every time he went to Paris and saw the admirable arrangements which existed there in the Grand Palais, he always wished there was a similar building in the heart of London. The White City and Olympia were all very well in their way, but they were far off. His thoughts always went back to those very delightful Exhibitions—he thought the first one was the Health Exhibition, which was followed by the Fisheries Exhibition and lastly, and best of all, by the Inventions Exhibition—which took place in the '80's, and which were held on the ground now occupied by the Natural History Museum and the Science Museum, and where there were delightful gardens, to which everybody could get from the West End of London in a few minutes. He had always thought that those Exhibitions had been most charming—perhaps because at that time he was rather younger than he was at the moment!

Sir Philip Magnus, Bt., in seconding the motion said he ventured to think that few persons could have been found with so characteristic a knowledge of what Exhibitions had been and what Exhibitions should be as Lord Askwith, who held the position of Head of the Exhibitions Committee of the Special Department of the Board of Trade, and who had given time and thought and years of service in connexion with matters appertaining to Exhibitions. Lord Askwith had given a most interesting history of International Exhibitions from the year 1851 to the present time, and had pointed out the several principles on which Exhibitions should be conducted, and had carefully explained—although perhaps the audience had not all fully understood it—the difference between vertical and horizontal Exhibitions. Lord Askwith had said that few persons could carry back their memories to the Exhibition of 1851. He was one. He remembered visiting that Exhibition on more than one occasion but he could not say from those visits that he could give anything like the full particulars of it which had been given by Lord Askwith. He could not even remember whether it was vertical or horizontal! He believed it was both. He was quite certain, however, that it must have been carried out with due preparation and with proper organisation, and that it had aroused the interest of all persons visiting it. The Exhibition of 1851 had been attended with results which possibly had not followed from any other Exhibition. The public owed to the Exhibition of 1851 the Art Museum at South Kensington; they owed to it the Science Museum which had recently been erected; the Imperial College of Science and Technology; the Natural History Museum, and many other buildings and institutions for the promotion of those objects which the Prince Consort had at heart. It was pleasant to realise that the organisation of the Exhibition of 1851 had been very largely effected by the Royal Society of Arts. Lord Askwith had not only stated what were the chief features of all the Exhibitions to which he had referred, but he had indicated very clearly with almost prophetic vision some of the principal results which might be expected to follow from the Exhibition of 1924. All he, personally, could hope was that the results of the Exhibition of 1921—which, after the description given by Lord Askwith, everybody would be most desirous of visiting—might be as great and as lasting, and as conducive to the advancement of civilisation as the Exhibition of 1851.

The vote of thanks was then put and carried unanimously.

Lord Askwith, in acknowledging the vote, said he was especially glad to have unearthed a very learned man who had visited the Exhibition of 1851, and who remembered nothing about it, but who recognised the great changes and results which had come from it. He trusted that Sir Philip Magnus would go to Wembley, would try to hunt about in his memory in order to compare the Exhibition of 1924 with the Exhibition of 1851, and that next year he would give the Society the result of his conclusions.

The proceedings then terminated.

NOTES ON BOOKS.

Crystallisation of Metals. By Colonel N. T. Belaiew, C.B. London: University of London Press, Ltd. 7s. 6d. net.

Colonel Belaiew's research on the crystalline forms assumed by metals, and of structures derived from crystalline forms are now presented to the English reader in a matured and revised form for the first time. The Author delivered a special course of lectures on the subject at the invitation of the University of London, and the present work is the text of the lectures, together with many illustrations in the letter-press, and a series of 21 photographic plates.

Beginning with a concise but profound study of the nature of a crystal, he emphasises the cleavage and space-lattice aspects as criteria for distinguishing between a vitreous mass and crystal; the influence of vectorial force in crystallisation is then touched on. Apart from the usual six systems as set forth in the text books, we have (pp. 35-88) a comprehensive study of dendritic groupings, skeleton forms and interlocked dendrites; this portion including the study of the Wiedmanstätten figures in meteoric iron and their parallels in artificial iron.

Structural equilibrium in solids is touched upon from the point of view that there is latent energy in an extended or out-spread form, whether by dendritic growths, lamellar condition, or broadly speaking any irregular form which arises during a dynamic stage, such as fusion and a resulting crystallisation; this energy constantly straining to reduce the total surface of the crystal or its complement, and to force it to assume or approximate to that form which has the minimum area, to wit, the sphere (p. 125). If the crystals are small, this spherodisation may be easier and more complete than if large. Thus this second-stage action of surface tension is studied and illustrated in wonderful and lucid detail, so charming and manifold, that description in a short notice is out of the question: but this aspect culminates in a unique but short account of the Damascene process and the working manner of an aged smith whom our author's old master and venerated tutor (p. 18), Tschernoff met at Zlatoust (p. 139); a smith, who by gentle heatings and subsequent forgings, under occasional tests by scrubbing and etching, knew how to spherodise thoroughly all the cementite particles.

This remarkable work will interest the student of physics, instruct and give thought to the ironmaster, and the illustrations, which culminate in plate XXI. Damascene blades, may give suggestions as to the near kinship of fine or spiritual art with technical fitness.

THE LONDON CITY CHURCHES: their Use, their Preservation and their Extended Use. Compiled and issued by the London Society. London: T. Fisher Unwin, Ltd. 1*s*.

A great deal of public interest was recently roused in the controversy which was carried on for some time in the press and elsewhere, over the problem of the London City Churches. People with an eye for the historic and the beautiful were aghast at the proposals for the demolition of some of Wren's masterpieces; others, intent upon the utilitarian, were equally shocked by the spectacle of valuable sites encumbered by buildings which were hardly ever used. In view of these divergent opinions it was a happy thought on the part of the London Society to issue this booklet which contains in the first place historic notes by the well-known antiquary, Dr. Philip Norman, on each of the forty-five churches; secondly, a tabular list of the churches and their present uses, and finally some suggestions for extending these uses, by the Rev. Arthur G. B. West, Rector of St. Dunstan's in the East. The great virtue of the pamphlet is that it gives one, in very brief space, a clear idea of the historic and architectural value of the churches, and of the extent to which they are at present being used. In several of the buildings much-needed rest-rooms are provided for work-girls, who, in order to take advantage of cheap workmen's tickets, have to come to the City long before their work begins; in others lectures are given, or organ recitals, or rooms are provided for boys' and girls' clubs; but when one looks through the tabular list of the churches one cannot help feeling that a great deal more use ought to be made of them before they can justify the continuance of their present existence.

ELECTRICAL MEASURING INSTRUMENTS AND SUPPLY METERS. By D. J. Bolton. London: Chapman and Hall, Ltd. 1923. 12*s*. 6*d*. net.

LINE CHARTS FOR ENGINEERS. By W. N. Rose. London: Chapman & Hall, Ltd. 1923. 6*s*. net.

These are volumes for the engineer's bookshelf, and they form part of Messrs. Chapman & Hall's "Directly Useful Technical Series," a series in which ready reference with practical instruction is the leading concept; while theoretical comments references or proofs are added when required.

Mr. Bolton's book of 328 pages gives a good insight into the use and nature of the whole range of present day electrical measuring devices. In illustration of its full detail, we may mention the double-sided plate which is inset between p. 132 and p. 133, this plate showing a single phase induction supply meter, a three-phase arrangement, maximum demand fittings, pendulum escapement for Aron meter, Aron meter with maximum demand fittings, and the mechanism for allowing prepayment.

In a concluding section modern electric pyrometry is treated of in a notably thorough manner; resistance method, the thermo-couple method and the many aspects of the radiation methods being considered. The optical aspects, as developed by Le Chatelier, Morse, Tinsley and others are considered at some length, the great advantage being the facility of taking a series of rapid measurements as to different parts of a furnace.

Mr. Rose in his treatise gives the engineer practical instructions as to making calculations instantly by means of line charts, the instructions for making the charts being lucid and detailed. One special advantage of the chart method is the elimination of casual or oversight errors to which calculations must always be liable. Naturally the accuracy of chart results depends on the care with which the charts are made, and also on the size of the chart. We may perhaps give a hint as to the convenience of flat-rolled sheets of zinc or aluminium about one-tenth of an inch thick and scribed with a fine steel point, then filled in with black. Chart No. 47 for powers and roots, is a good example of a moderately complex chart which is easy to construct or to use; while No. 44, a chart for Unwin's welded steel flue formula is an example of many charts quite special to engineering practice.

Mr. Rose deserves high praise for the thoroughly practical way in which he presents his subject to the reader, and as an illustration of his thoughtfulness we may mention Nos. 21 and 22 charts for proportion, each suited to a slightly different mentality.

We may conclude by remarking that both the books under notice can be unreservedly recommended.

THE CANTON FEATHER INDUSTRY.

Feathers of two kinds—those used for filling cushions, pillows and mattresses and those classed as ornamental or fancy feathers and used for hats and dresses—have been exported from China for many years. In the Canton district, writes the United States Vice-Consul at Canton, feathers of the ordinary type are gathered up-country by pedlers who go from village to village collecting small quantities of duck, fowl, and other kinds of feathers.

What the pedlers gather is passed on to larger dealers, who in turn ship the feathers by junk to Canton and Fatshan. At these two places the feathers are half sorted and sold to the eight or ten large Chinese feather merchants who supply the foreign commission houses.

There are 25 or 30 grades of these feathers, all of which are sold by the picul of 133⅓ pounds. The chief demand in Europe comes from France and the Scandinavian countries, where feathers for use in making feather beds are in favour. Feathers sorted for Europe may contain 30 per cent. dirt. A better grade is demanded for the American market, the maximum of dirt being fixed at 15 per cent.

When the feathers reach the foreign commission houses at Canton, the dirt and the long feathers are removed by hand. Some firms use an electric blowing machine to test samples before packing. This machine removes the dust so that the feathers may be inspected more closely. When ready for export, the feathers are packed either in loose bales of 1½ piculs or in hydraulic pressed bales of 3 piculs.

There are many kinds of ornamental or fancy feathers exported from Canton, the most popular of which are the silver and golden pheasant, numidae, and peacock feathers. In 1919, 1,542 U.S. dollars' worth of ornamental feathers were exported from Canton in 1919, 3,171 dollars' worth in 1920, and 3,920 dollars' worth in 1921.

THE BARBADOS ALOE INDUSTRY.

At a recent meeting of the Barbados Agricultural Society, Mr. Bourne, Acting Director of Agriculture, stated that he believed it would be profitable to grow aloes again in that island for the American market. In the opinion of Mr. Bourne, there are about 3,000 acres of waste land along the coast in Christ Church, St. Lucy, St. Philip, St. John, and St. Joseph Parishes suitable for the growth of the plant. Aloes were raised in Barbados for commercial purposes as far back as 1657, and the industry was kept up until the early part of the present century. It was abandoned then, writes the United States Consul at Bridgetown, because Curacao and other Dutch Islands had begun growing aloes, which resulted in over-production and a consequent drop in price.

The aloe plant grows to an average height of 2 feet, with a number of leaves which are about 4 inches broad, three-quarters of an inch thick, and 18 inches long. The commercial value of the aloes lies in the juice contained in these leaves. The leaves are ripe for cutting at the end of the first year and bear every year for six years, after which the yield falls off. The average yield for full-grown plants is about 500 pounds per acre. When the plant begins to bloom, which is in February and March, the leaves are cut off and the juice is collected in gourds, boiled, and allowed to cool.

Aloes are planted in rows about 2 feet apart, the distance between each plant being one foot. All that is required in the cultivation of aloes is to manure the soil well before planting and then to keep the land weeded. One advantage of this crop is that other crops, such as okra, guinea corn, and yam, can be grown between the rows; also the gourd vine, the gourds of which are afterwards used to contain the juice of the aloes.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

November 28.—Sir Henry John Gauvain, M.A., M.D., M.Ch., Medical Superintendent of the Lord Mayor Treloar Cripples Hospital, "The Effect of Sun, Sea and Open-air in the Treatment of Disease." Lord Dawson of Penn, G.C.V.O., K.C.M.G., M.D., F.R.C.P., will preside.

December 5.—Arthur William Hill, M.A., Sc.D., F.R.S., F.L.S., Director of the Royal Botanic Gardens, Kew, "The Work of the Royal Botanic Gardens, Kew." Charles Albert Seward, M.A., F.R.S., F.G.S., F.L.S., Professor of Botany in the University of Cambridge, will preside.

December 12.—Sir Frank Baines, C.B.E., M.V.O., Director of Works, H.M. Office of Works, "The Preservation of

Historic Buildings and Ancient Monuments." **Sir Aston Webb**, K.C.V.O., C.B., P.R.A., will preside.

INDIAN SECTION.

Friday afternoons, at 4.30 o'clock.

December 7.—William Foster, C.I.E., Historiographer, India Office, "The Archives of the Honourable East India Company." (Sir George Birdwood Memorial Lecture.) **The Rt. Hon. Viscount Peel**, G.B.E., Secretary of State for India, will preside.

DOMINIONS AND COLONIES SECTION.

Tuesday afternoon, at 4.30 o'clock.

November 27.—Viscount Burnham, C.H., LL.D., D.Litt., M.A., "The West Indies." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

December 17 (Monday.)—**Wm. C. Noxon**, Agent-General for Ontario, "Settlement within the Empire."

PAPERS TO BE READ AFTER CHRISTMAS.

G. Albert Smith, "Cinematography in Natural Colours—further developments" (with illustrations—scenes from H.R.H. The Prince of Wales's Tour in India).

Iyemasa Tokugawa, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Sir Richard Arthur Surtees Paget, Bt., "Fused Silica and its use as a Refractory Material."

H. Maxwell Lefroy, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle."

Percival James Burgess, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

Charles S. Myers, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

T. Thorne Baker, "Photography in Industry, Science and Medicine."

Sir Richard M. Dane, K.C.I.E., Commissioner North India, Salt Revenue, 1898-1907; Foreign Chief Inspector, Salt Revenue, China, 1913-18, "Salt Manufacture in India and China."

Brigadier-General Henry Alfred Young, C.I.E., C.B.E., late R.A., Director of Ordnance Factories, India, 1917-21, "The Indian Ordnance Factories."

Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Colonel H. L. Crosthwait, C.I.E., R.E., retd., late Superintendent, Survey of India, "The Survey of India." Sir Thomas H. Holland, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, will preside.

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

F. W. Walker, "The Commercial Future of the Backward Races, with Special Reference to Papua." **Sir George R. Le Hunte**, G.C.M.G., will preside.

INDIAN SECTION.

Friday afternoons, at 4.30 o'clock.

January 4, 18, February 15, March 21, May 2.

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons, at 4.30 o'clock.

February 5, March 4, April 1, May 27.

CANTOR LECTURES.

Monday evenings, at 8 o'clock.

Aldred F. Barker, M.Sc., Professor of Textile Industries, The University, Leeds, "Recent Progress in the Wool Industries." Two Lectures. December 3, 10.

Eric Keightley Rideal, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University Cambridge, "Colloid Chemistry." Three Lectures. January 21, 28; February 4.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

COBB LECTURES.

Monday evenings, at 8 o'clock.

Dr. T. Slater Price, Director of Research, British Photographic Research

Association, "Certain Fundamental Problems in Photography." Three Lectures March 24, 31; April 7.

DR. MANN JUVENILE LECTURES.

(Special tickets are required for these Lectures).

Wednesday afternoons, at 3 o'clock.

DR. WILLIAM ARTHUR BONE, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology. "Fire and Explosions." Two Lectures. January 2, 9. The Lectures will be fully illustrated with experiments.

MRS. JULIA W. HENSHAW, F.R.G.S., Croix de Guerre, "Among the Selkirk Mountains of Canada (with ice-axe and camera)." One Lecture. January 16. The Lecture will be fully illustrated with hand-painted lantern slides.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, NOVEMBER 26..Health, People's League of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Dr. Saleeby, "Sunlight and Health." (Lecture IV.)

University of London, King's College for Women, 61, Campden Hill Road, W., 5 p.m. Prof. V. H. Mottram, "Newer Aspects of Nutrition." (Lecture VIII.)

Swiney Lecture, King's College, Strand, W.C., 5.30 p.m. Dr. W. T. Gordon, "Gem Minerals and their Uses in Art and Industry." (Lecture IV., Diamond.)

Faraday Society, at the Institution of Electrical Engineers, Victoria Embankment, W.C. Conference on Electrode Reactions and Equilibria, 3 p.m., Part I. 1. Dr. E. K. Rideal, Introductory Address—"The Mechanism of the Reversible Electrode". 2. Prof. E. Billmann, "Oxidation and Reduction Potentials of Organic Compounds." 3. Dr. J. Heyrovsky, "The Process at the Mercury-dropping Cathode. Part I.: The Deposition of Metals." 4. Prof. A. W. Porter, "Note on the Standardisation of the Sign of the Potential." 5. Dr. J. N. Pring, "The Determination of Affinity Constants by the Hydrogen and Quinhydrone Electrodes." 6. Prof. E. Baur, "Electrode-Potentials in Non-Aqueous Solutions." 7. M Shikata, "Concentration Cells and Electrolysis of Sodium Ethoxide Solutions." 8 Mr. J. A. V. Butler, "Studies in Heterogeneous Equilibrium" 5.30. Part II., "Irreversible Electrode Phenomena." 1 Prof. A. J. Allmand and Mr. H. J. T. Ellingham, "Introductory Address." 2. Prof. A. Smits, "Electromotive Equilibrium and Polarisation." 3. Mr. N. V. S. Knibbs, "The Gas Film Theory of Overvoltage." 4. Mr. U R. Evans, "The Influence of Obstructive Films in Anodic Processes."

TUESDAY, NOVEMBER 27..University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. W. J. Perry, "The Pan Pacific Congress."

At King's College, Strand, W.C., Mr. E. F. Jacob, "Some Popular Misreadings of Mediæval History" (Lecture I.). 5.30 p.m., Miss Hilda Oakeley, "The Roots of Early Greek Philosophy" (Lecture I.). 5.30 p.m. Prof. H. C. H. Carpenter, "Metallic Crystals and their Properties" (Lecture I.).

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Captain C. H. Armitage, "The Gambia, our oldest West African Colony."

Anthropological Institute, at the Royal Society, Burlington House, Piccadilly, W., 8.15 p.m. Dr. E. H. Hunt, "Hyderabad Cairn Burials and their Significance."

WEDNESDAY, NOVEMBER 28..University of London, University College, Gower Street, W.C., 5.30 p.m. Dr. P. Harting, "Vondel's Lucifer and Milton's Paradise Lost."

Swiney Lectures, King's College, Strand, W.C., 5.30 p.m. Dr. W. T. Gordon "Gem Minerals and their uses in Art and Industry. (Lecture V., Corundum.)"

Automobile Engineers, Milton Hall, Deansgate, Manchester, Mr. L. Murphy, "The Misuse of the Internal Combustion Engine and Suggestions for its more Efficient Application."

Microscopical Society, 20, Hanover Square, W., 7 p.m. 1. Mr. C. Beck, "A New Projection Microscope for measuring Fine Wires and Fabrics to 1-50,000th inch. 2. Messrs. Adam Hilger, "Dr. Müller's X-Ray Spectrograph for the Examination of Sub-Microscopic Crystalline Structures." 3. Mr. J. E. Barnard, "The Characteristics of a Microscope for general and special purposes. The Tests for Mechanical Efficiency that should be satisfied." 4. Dr. S. H. Browning, "The Application of the Microscope to Industrial Diseases." 5. Mr. C. A. Newton, "The Microscope in the Examination of Condensed Milk."

Japan Society, 22, Russell Square, W.C., 5 p.m., Commander O. T. Tuck, "Some Comic Mediæval Plays."

THURSDAY, NOVEMBER 29..Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Sqdrn.-Ldr. Maycock, "Airmanship at Sea."

University of London, University College, Gower Street, W.C., 5.30 p.m. Sir William Collins, "The Life and Doctrine of Sir Edwin Chadwick"

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr H. G Williams, "Foreign Exchange: its Effect on Industry and Cost of Living"

Antiquaries, Society of, Burlington House Piccadilly, W., 8.30 p.m

Linnean Society, Burlington House, Piccadilly W., 5 p.m.

Electrical Engineers, Victoria Embankment, W.C., 6 p.m. (Joint Meeting with the Physical Society.) Discussion on "Loud Speaking Telephones."

Mining Engineers, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 11 a.m. Annual General Meeting. 1 Prof. R. W. Dron, "Hydraulic Stowage at the Dalzell and Broomside Collieries" 2. Prof. K. N. Moss, "Some Effects of High Air-Temperatures upon the Miner." 3. Mr. T. D. Jones, "Strata Temperatures in South Wales, including Pembrokeshire." 4. Mr. G. Coles, "The Specific Heat of Coal." 5. Sir William Ellis, "The Position of Mechanical Engineering in Colliery Operations."

London County Council, Geffrye Museum, Kingsland Road, E., 7.30 p.m. Mr. H. A. Tipping, "House Equipment under Elizabeth."

FRIDAY, NOVEMBER 30..Aeronautical Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.30 p.m. Mr. A. H. G. Fokker, "The Result of Twelve Years' Welded Tube Construction and the Development of Cantilever Wings."

University of London, at the London School of Economics, Houghton Street, W.C., 5 p.m. Prof. S. E. Morison, "The Origin of the Monroe Doctrine."

Swiney Lecture, King's College, Strand, 5.30 p.m. Dr. W. T. Gordon, "Gem Minerals and their Uses in Art and Industry." (Lecture VI.)

Junior Engineers, Institution of, 39, Victoria Street, S.W., 7.30 p.m. Mr. S. C. Saunders, "Notes on Designs of Paraffin Motors."

Mechanical Engineers, Storey's Gate, Westminster, S.W., 6 p.m. Prof. A. L. Mellanby, "Clyde Marine Oil Engines."

Journal of the Royal Society of Arts.

No. 3,706. VOL. LXXII.

FRIDAY, NOVEMBER 30, 1923.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2).

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 3rd, at 8 p.m. (Cantor Lecture.) **ALDRED F. BARKER**, M.Sc., Professor of Textile Industries, The University, Leeds, "Recent Progress in the Wool Industries." (Lecture I.)

WEDNESDAY, DECEMBER 5th, at 8 p.m. (Ordinary Meeting.) **ARTHUR WILLIAM HILL**, M.A., Sc.D., F.R.S., F.L.S., Director of the Royal Botanic Gardens, Kew, "The Work of the Royal Botanic Gardens, Kew." **CHARLES ALBERT SEWARD**, M.A., F.R.S., F.G.S., F.L.S., Professor of Botany in the University of Cambridge, will preside.

FRIDAY, DECEMBER 7th, at 4.30 p.m. (Indian Section.) **WILLIAM FOSTER**, C.I.E., Historiographer, India Office, "The Archives of the Honourable East India Company." (Sir George Birdwood Memorial Lecture.) **THE RT. HON. VISCOUNT PEEL**, G.B.E., Secretary of State for India, will preside.

CANTOR LECTURES.

On MONDAY, NOVEMBER 19th, 1923, MR. **SAMUEL HENRY DAVIES**, M.Sc., F.I.C., delivered the second and final lecture of his course on "The Cultivation of Cocoa in British Tropical Colonies."

On the motion of the Chairman, a vote of thanks was accorded to Mr. Davies for his interesting course.

The lectures will be published in the *Journal* during the Christmas recess.

SECOND ORDINARY MEETING.

WEDNESDAY, NOVEMBER 21st, 1923, MR. **BERNARD RACKHAM**, of the Victoria and Albert Museum, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Auckland, George Frederick, London.
Elwell, C. F., London.
Harding, William, Loughborough.
Hodgkinson, Thomas Walter, Purley, Surrey.
Hoyer, Anton Gotfred, Durban, S. Africa.
Joughin, Walter James, London
Levine, Professor Victor E., Ph.D., Omaha, U.S.A.
Lloyd, William Henry, Twickenham.
McEwen, Alfred, New York City, U.S.A.
Medlicott, Samuel Thomas, London.
Sleigh, Arthur Crofton, London.
Trusler, William Thomas, Enfield.
Williams, Samuel Powell, Bradford.

The candidates proposed at the Opening Meeting, on November 7th, of whom a list was published in the *Journal* of November 16th (pages 899-900), were duly elected Fellows of the Society.

A paper on "Forgeries of Ancient Stained Glass," was read by Mr. J. A. Knowles.

The paper and discussion will be published in a subsequent number of the *Journal.*

MANN JUVENILE LECTURES.

Under the Mann Trust a short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, 2nd and 9th January, 1924, at 3 p.m., by **DR. WILLIAM ARTHUR BONE**, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology, on "Fire and Explosions." The lectures will be fully illustrated with experiments.

A lecture will also be given on Wednesday, January 16th, at 3 p.m., by **MRS. JULIA W. HENSHAW**, F.R.G.S., Croix de Guerre, entitled "Among the Selkirk Mountains of Canada (with ice-axe and camera)." The lecture will be fully illustrated with hand-painted lantern slides.

Special tickets are required for these two sets of lectures. A sufficient number to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply to the Secretary at once stating for which lectures they desire tickets.

PROCEEDINGS OF THE SOCIETY.

EXTRA MEETING.

WEDNESDAY, OCTOBER 3RD, 1923.

MR. GEORGE E. BROWN, F.I.C. (Editor of the "British Journal of Photography") in the Chair.

THE CHAIRMAN said that it was hardly necessary for him to introduce Dr. Mees to a Royal Society of Arts audience. They had listened to Dr. Mees in that room both before and after he became Director of the Eastman Research Laboratories at Rochester, U.S.A. They were very fortunate in that circumstances had made it possible for Dr. Mees to be again in this country for a few months.

The Paper read was :—

AMATEUR CINEMATOGRAPHY.

By C. E. K. MEES, D.Sc.,

Director of Research and Development, Eastman Kodak Company.

Amateurs have played a great part in the development of photography. The early workers in photography were naturally amateurs, though the first successful process, that of Daguerre, was utilized chiefly for making portraits and was the process first used by professional photographers. While Daguerre's process was being exploited, however, Fox Talbot discovered his process in which a negative was made and then printed, the practice followed at the present time, and in which the exposure, insufficient to produce a visible image, was followed by development to obtain a negative of sufficient strength for printing. Talbot, in fact, laid the foundations for our modern systems of photography. Scott Archer, the inventor of the wet collodion process, which followed the calotype process of Fox Talbot, and Maddox, who made the first gelatine emulsion, were both amateurs, and all the early work on dry plates was done by amateurs until about 1880, when the manufacture of dry plates on a commercial scale was fully established.

Important as was the work of amateurs, however, the possibilities of amateur photography were necessarily limited by the very cumbersome equipment which was required for the wet plate process, and even when dry plates became available, the portability of apparatus and the simplicity of photography were very far from their present level. Marked as has been the improvement in apparatus for the utilization of dry plates, the greatest step in the making of photography available to everybody was the development of the film camera.

The causes that restricted the use of photography by amateurs have operated to limit the use of motion picture photography by other than professional photographers. The apparatus required is very heavy and cumbersome; the standard motion picture camera, tripod, and magazines form a heavy load for one man, and, in addition the cost of the film is very great. The cost of making a negative and projecting the picture upon the screen is approximately sevenpence for each foot of film which in projection lasts one second on the screen.

Motion pictures are obtained by making a series of photographs of the object upon a long strip of film, each picture being a representation of the object at that particular moment. Sixteen of these pictures are taken every second, and when they are projected upon the screen, the different phases of movement blend together and give the appearance of motion. The film is held stationary while the picture is taken or projected and then is moved forward very quickly to a new position and is held still again so that sixteen times a second the film is moved forward, and sixteen times a second it must be stopped. This movement is accomplished by what is called the intermittent mechanism in the camera or projector, the film being moved by claws which catch in the perforations, pull it down into its new position by the height of one picture, and then come out of the perforations again, leaving the film motionless, until, as the movement of the mechanism continues, they re-engage and pull the film down again. In projectors a sprocket with teeth on it is sometimes moved intermittently to pull the film down instead of claws, which engage intermittently in the perforations.

The whole system of amateur motion picture photography which has been worked out by the Kodak company is founded on a film smaller than that used in the standard camera and on a new process used in finishing it, but of almost equal importance is the design of the apparatus in which the film must be used.

The camera is, on the whole, of standard type. It resembles, in fact, a standard motion picture camera of the highest grade, but in amateur size. No attempt has been made to cheapen the camera by the omission of any necessary feature or by any undue

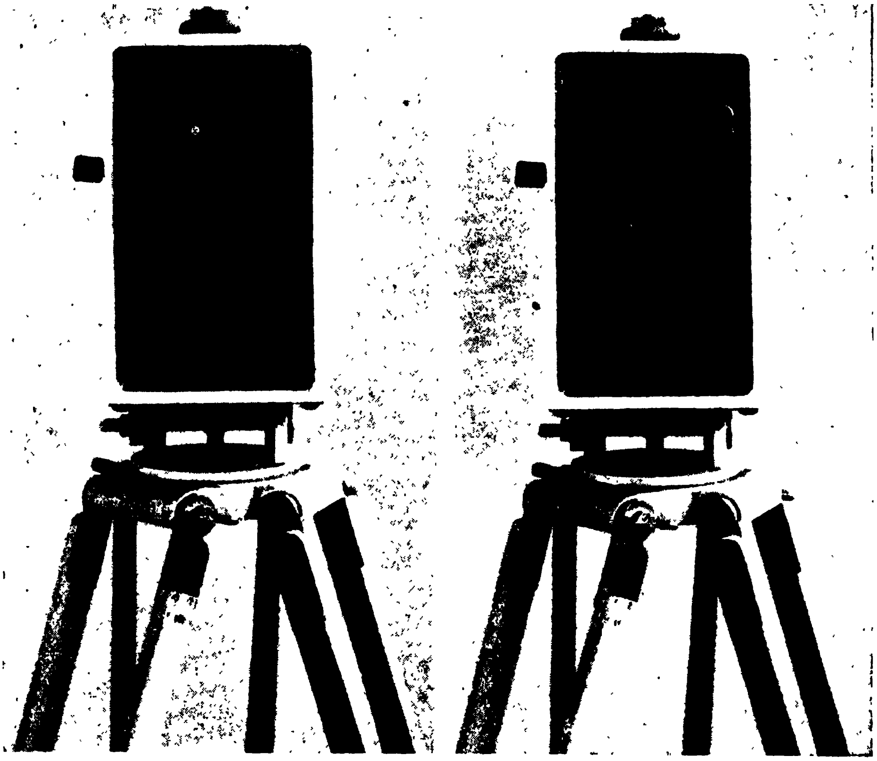

FIG. 1.—Front of the Cine Kodak.

simplification. The object was to produce an instrument which would take pictures equal in every respect to those which the professional could obtain. The weight of the camera loaded is eight pounds and of the tripod with its special head eight pounds, so that the camera ready for use weighs sixteen pounds. The lens is an anastigmat working at *f* 3.5, which enables photographs to be taken under difficult conditions of light. The finder is just above the lens (Fig. 1) and by an attachment changes the position of its image as the lens is focused, thus always showing the image through the centre of the field. The lens has a focusing lever carried through to the back which can be set for any distance from infinity to 4 feet. The diaphragm control is in the left hand corner and can thus be read easily. In the centre of the back is the footage indicator which shows the number of feet of film which have been used (Fig. 2). The crank is put out of the way into a recess when not required (Fig. 3). It is turned normally twice a second, taking pictures at the standard rate of sixteen pictures a second. The mechanism is of the standard motion picture type (Fig. 4), the film being pulled down by means of a claw operated by a cam mechanism.

In order to load the camera, the film spool, (Fig. 5) has its outer cover removed and is then placed on the upper spindle provided for it. To the film there is attached a paper leader of the same width as the film and perforated in the same way. Two feet of this are pulled out and are threaded over the sprocket of the camera on to which it is held by the presser plate, down through the gate, where the claws engage in the perforation, a loop being formed above the gate as is indicated on the camera mechanism, through another loop, which is also indicated, back under the sprocket, and thence to the bottom spool in which the end of the paper is inserted and a few turns made to ensure everything being right. The inner cover is, then removed from the spool, the film being protected for a few seconds only by the paper leader. The door is placed on the camera, the footage indicator at the back of the camera is then set to 96 (indicated by a star) and the four remaining feet of red

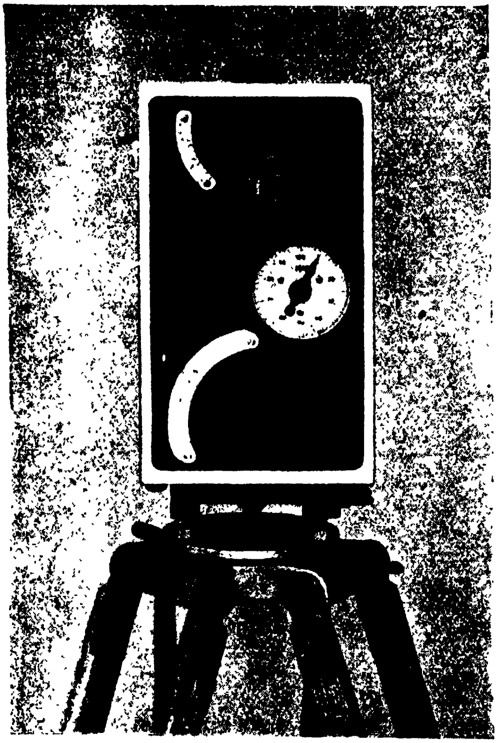

Fig. 2.—Back of the Cine Kodak.

paper leader wound off. The indicator then points to zero, and the camera is ready for use loaded with 100 feet of film. After all the film has been exposed, cranking is continued for six more feet, thus winding up another paper leader on to the exposed film. The camera door can then be opened, the covers put on the spool of exposed film, and the spool removed and sent to the Kodak Company for development.

The camera is used on a special tripod, made to be as light and yet as rigid as possible, the tripod head being made to rotate and to move in a vertical direction for the convenience of the operator, (Fig. 6). It is not intended that the tripod head should be used to produce panoramic pictures by rotating while the camera is being cranked. It is extremely difficult to do this smoothly, and the result obtained rarely gives a pleasing impression when projected. A rotating head is necessary to enable the camera to be moved in direction rapidly in order to follow objects in the field. After the film has been developed, the positive is ready for projection.

The projector, which is called the "Kodascope," is, like the camera, a standard projector of the highest grade with such

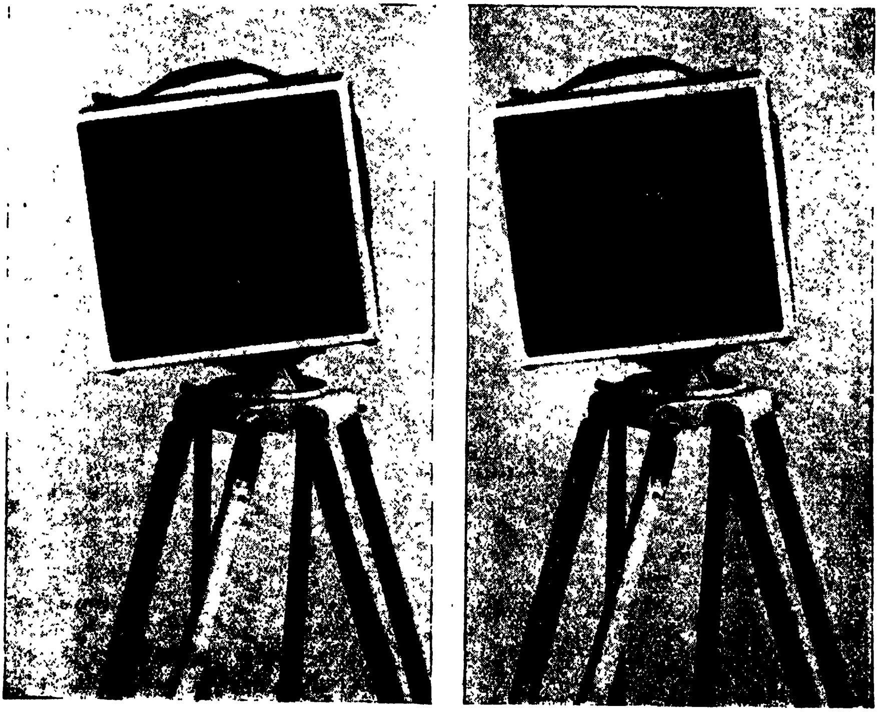

Fig. 3.—Crank side of the Cine Kodak.

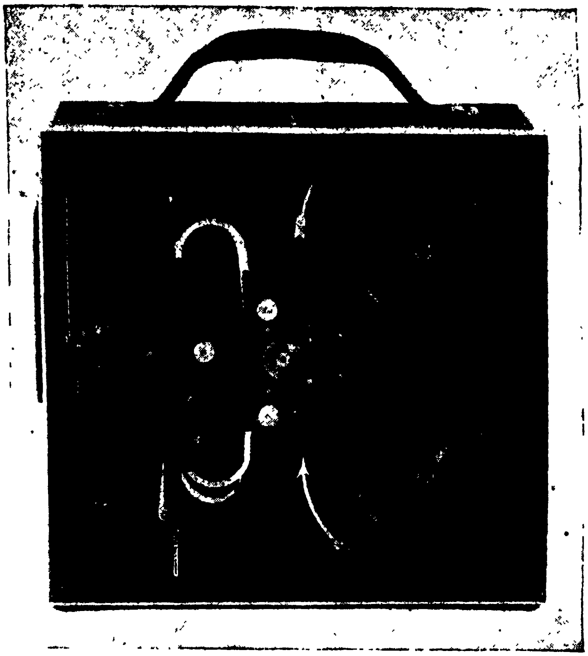

Fig. 4.—Mechanism with the door removed—with film in position for exposing.

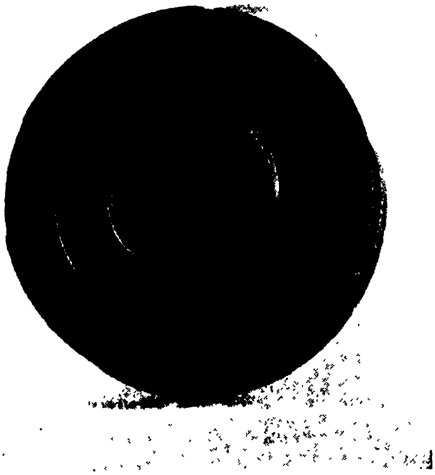

Fig. 5.—Film Spool.

changes as are necessary to make it suitable for use by amateurs and for the small film (Fig. 7). The mechanism is of the same claw and cam type as the camera. The film, which is usually assembled in 400 foot reels which are equivalent to 1000 feet standard reels and last for 16 minutes on the screen, is placed on the upper shaft and the film is threaded on to an upper sprocket which feeds the film in a loop to the gate, then through the lower sprocket to the take up reel, which is placed on the bottom shaft. The Kodascope is driven by a motor, and light is supplied by a lamp through a condenser which is attached just behind the gate. The lens is of very large aperture, specially designed and made, and has a focusing mechanism of a convenient type. This large aperture lens and efficient condenser system give a bright image on a screen with a small lamp, and for home use the apparatus is arranged to give a satisfactorily bright screen of 4½ feet in width, the two standard sizes of screens for home or class-room use being 30″ × 40″, which is large enough for the ordinary room, and 40″ × 54″, which is preferable for very large rooms or class-rooms. By changing the lamp house and attaching a more powerful lamp with a special condenser system, a school can use a seven foot screen and obtain ample light on it. The Kodascope is entirely automatic in its operation. Once a film is threaded, there is no need to go near the machine until the film is exhausted, the user can sit at ease among his friends while his pictures are being shown. The machine uses a lens of 2″ focal length and fills the 30″ x 40″ screen at 18 feet distance

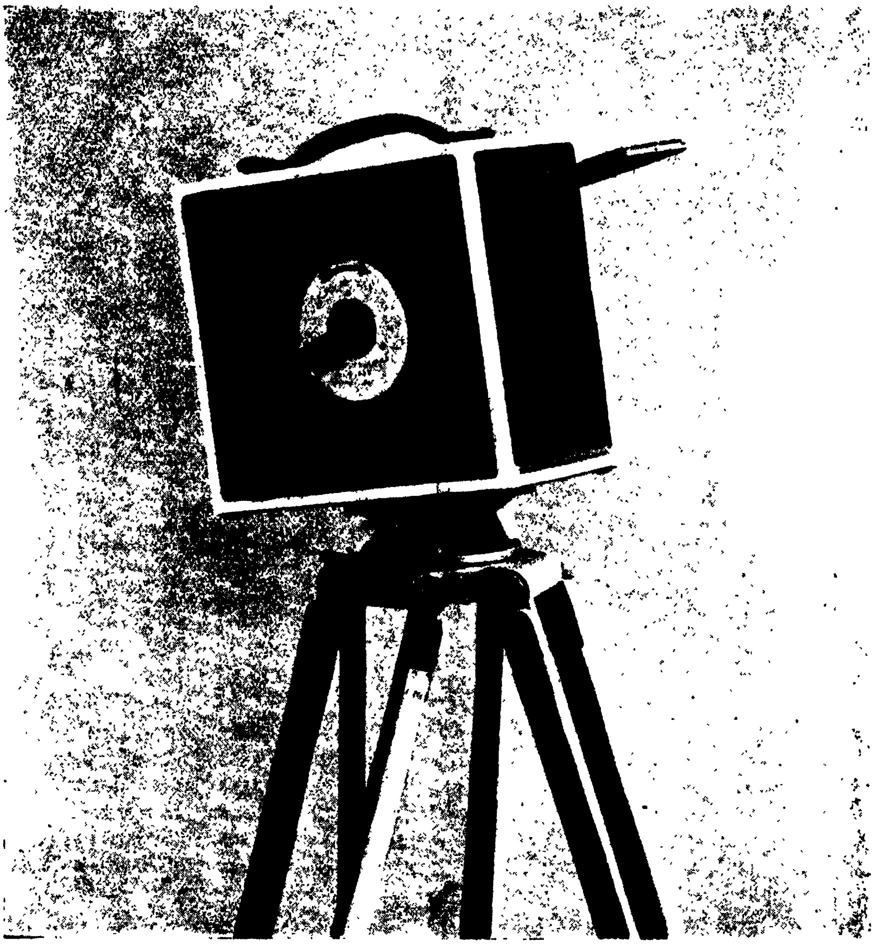

FIG. 6.—Cine Kodak on its Tripod.

and the 40″ x 54″ screen at 24 feet distance. The weight of the Kodascope projector with its motor ready for use is twenty-two pounds.

The quality of the picture depends upon three points: the optical perfection of the systems used in the camera and projector, on which depends the sharpness of the pictures; the mechanical perfection, on which depends the steadiness of the picture on the screen; and the photographic quality of the emulsion and the process used, on which depends the faithfulness with which the brightness in the light intensities in the original pictures are reproduced and its consequent fidelity to nature and also the appearance on the screen as regards any structure or graininess.

Now, when a small film is used for amateur cinematography, the accuracy required on all these accounts is increased, although fortunately the strains both on the film and on the mechanism are decreased. The lenses must be of the highest quality, since the small pictures will be enlarged to a greater degree than big pictures and must consequently be sharper. . The mechanical accuracy must be higher, since any failure in perfection of register will be perceptible. The photographic quality must be at least as good as that of standard size pictures if the user is to be satisfied with the results.

A number of inventors have designed cameras and projectors for amateur use in which the pictures were much smaller than those used on the standard film. The chief difficulty which is introduced when small pictures are used is the graininess which such a small picture shows when it is enlarged upon the screen. A photographic image of any kind is composed of small clumps of the microscopic silver

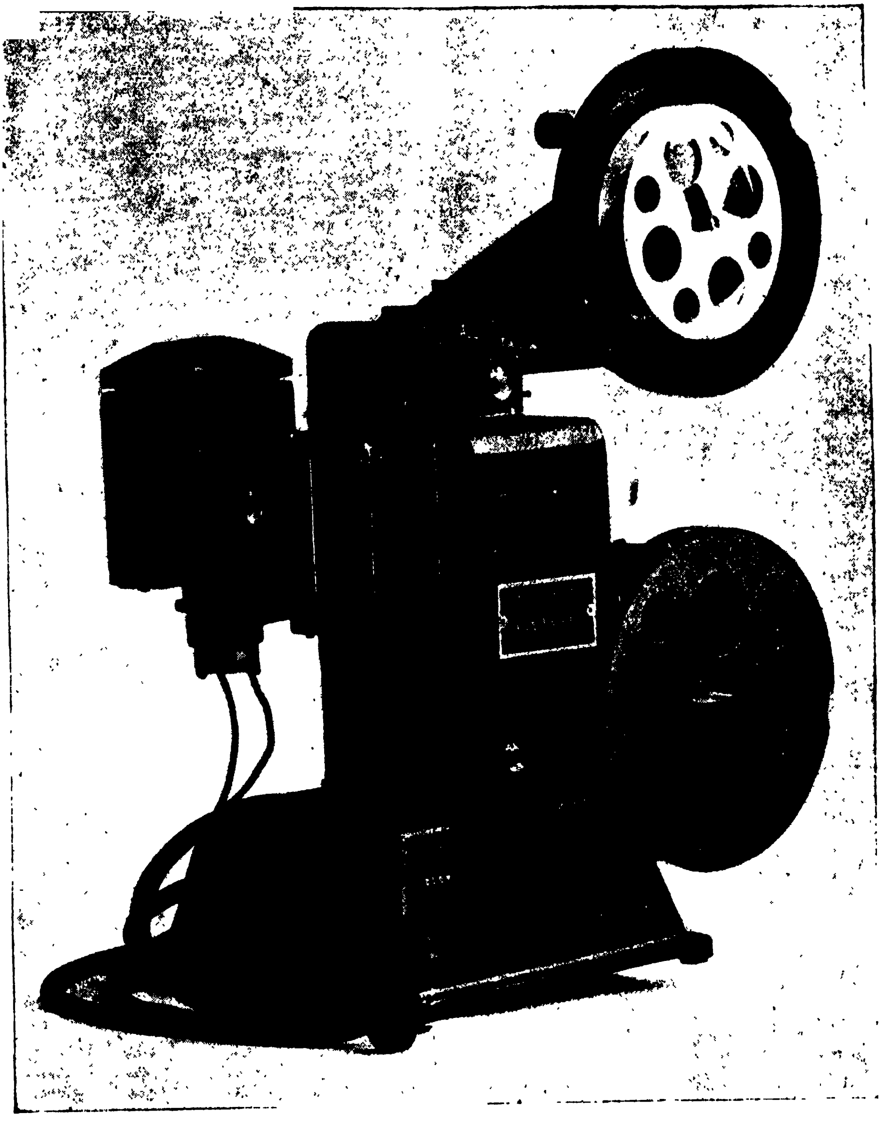

FIG. 7.—Kodascope with lamp house open

grains, and when it is very much enlarged these clumps show and give a structure to the image. In Fig. 8 we see at the left, at A, a very small image, and on the right the same image enlarged 55 diameters. It will be seen that the detail of the image is entirely lost owing to the graininess shown. The graininess in ordinary motion pictures is very slight but is visible when the observer stands close to the screen, and it is clear that if much smaller pictures are to be used on the screen and enlarged to the same extent the results would be greatly inferior to those obtained by the use of standard apparatus and that unless something can be done to diminish the graininess, the results would not be satisfactory in comparison with the pictures shown at the theatres. Moreover, even when a smaller film is used the cost, although diminished, is still high ; a negative must be developed and a positive printed from it. This printing requires very skilled work. It is rare in standard motion picture practice for the first print from a negative to be entirely satisfactory, and to get a single print of high quality from every negative would be very difficult. The use of a small film treated like the regular film

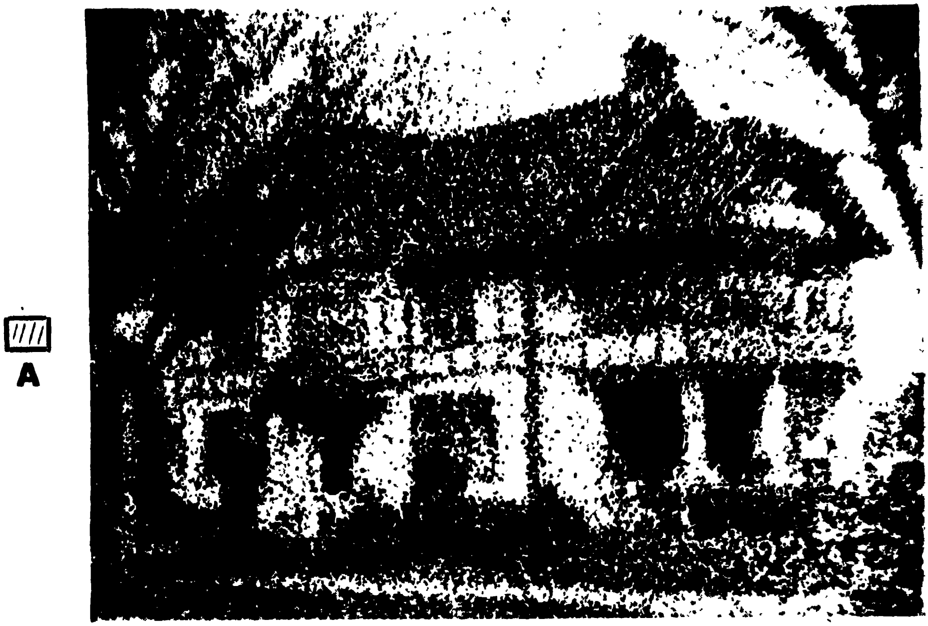

FIG. 8.—On left, small image marked A; on right, enlargement of small image to 55 diameters showing graininess.

would, therefore, present two difficulties: high cost or low quality of results and the graininess of the image.

The ideal process for amateur use would clearly be one in which the original picture was available for projection on to the screen. In still photography it is an advantage to make negatives, because usually a number of prints are required from a single picture, but in motion picture work in most cases an amateur is interested in getting only a single print, and there are great advantages in a process which enables a positive to be obtained by the first direct treatment of the original exposure. The preparation of positives direct is well known in photography. The usual method is to develop the exposed image and then to dissolve out the silver in a "bleaching" bath, as it is called, which oxidises the silver and leaves the undeveloped silver bromide intact. After exposure to light, this remaining silver bromide is developed in its turn and this gives a positive. This process has two disadvantages: It can give satisfactory results only through a very small range of original exposures because, if the exposure is too low, the amount of silver halide undeveloped is correspondingly large, and the final image is dense, while if the first exposure is heavy, there is not enough silver salt left to form a satisfactory image. It is also dependent upon very exact evenness of coating. If the coating is too thick, then the whole positive will be overlaid by a deposit of silver which the first exposure could not reach, and if it is too thin, there will not be sufficient silver to give density in the final image. Variations in the evenness of coating will show very badly in the finished picture. As the result of a good deal of research work, a process was devised in our research laboratory which overcame these disadvantages. This process depends essentially upon the exact adjustment of the exposure which is given to the residual silver bromide left after the removal of the silver image first developed. It is possible now to obtain first-class positives upon coatings of any thickness whatever, the density not being dependent upon the evenness of the coating, and the control over variations of exposure being quite equal to that obtainable by the usual process of making the positive by printing from a finished negative. Moreover, these reversed pictures were found to be astonishingly free from graininess. The graininess is due to the large clumps of silver halide grains present in the emulsion. These large clumps are more sensitive to light than small or widely separated grains, and therefore when a short exposure is made,

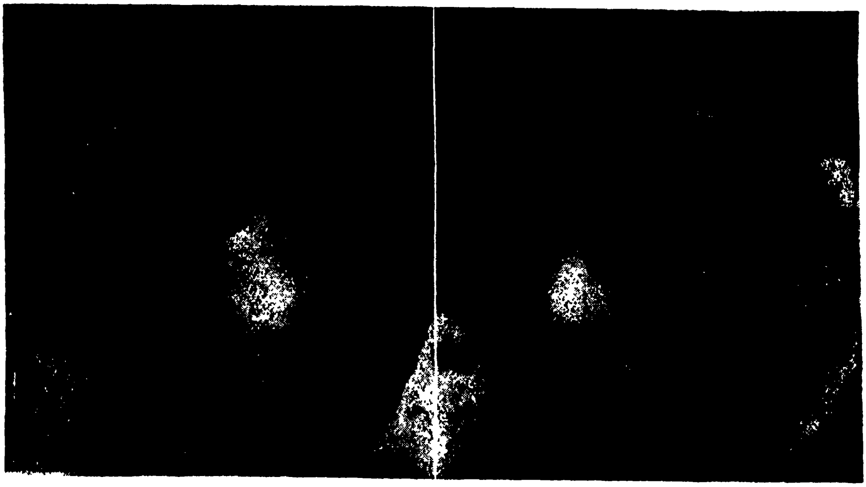

FIG. 9.—Enlargement from standard film and Kodascope positive to same size to show relative graininess, the Kodascope positive being enlarged 2½ times more than the standard film.

the large clumps are the first to become exposed. These are removed in the reversal process, and the final image is made up of the grains of the least sensitiveness. Since these are the smallest grains and the smallest clumps of grains, such a direct positive image shows very little graininess. In Fig. 9 there is shown at the left, an enlargement from a standard motion picture print, and on the right the same scene taken on the small film and enlarged until it is the same size as the picture taken on the standard film. It will be seen that the small film is so free from graininess that a picture of the same size shows no more graininess than if it had been made by the standard process.

The production of the positive by the new

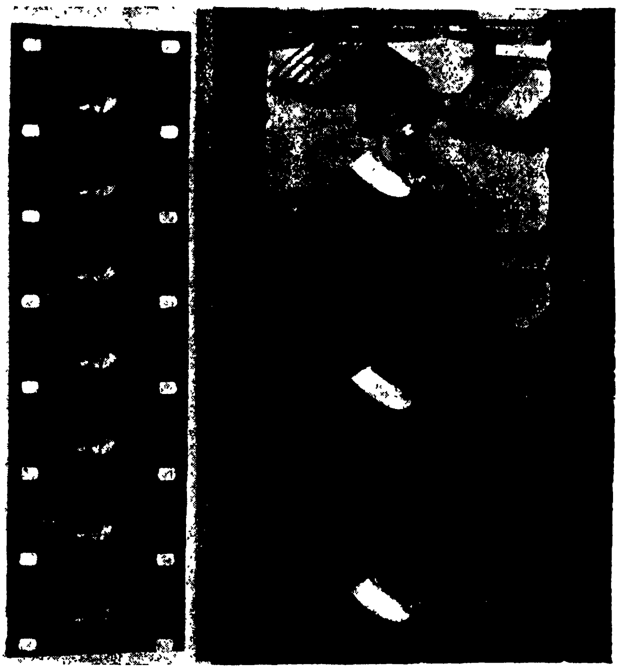

FIG. 10.—Kodascope film side by side with standard film.

process is quite a complicated matter and requires very special and complicated equipment since the film has to go through a great number of treatments compared with the simple operation of developing and fixing to which motion picture film is usually exposed. For this reason it has been decided that for the present, at any rate, the Kodak Company should undertake this work itself, and it is installing equipment which will make it possible to finish all the film that can be taken with the cameras in use.

Naturally, many amateurs will wish to have more than one print for some special reason, and this is provided for by the use of a special printer in which a positive can be duplicated, the duplicate being reversed into a positive in the same way as the original picture. In this way, it is possible to obtain duplicates at the same cost as the original picture, and though this is somewhat higher than the cost of making prints from an ordinary negative, there is no question that the use of the reversal process will greatly cheapen the production of motion pictures by amateurs. The small pictures can be enlarged in special printers to make pictures of the standard size required for theatres. This will, no doubt, not be required very often, but what will be done to a very large extent is that pictures of standard size will be reduced to make the small prints suitable for projection in the Kodascope.

Fig. 10 shows Kodascope film side by side with the standard film. The Kodascope film was standardized at 16mm. in width compared with the standard width of 35mm. The picture is 1 cm. x ¾ cm. or 10 x 7½ mm. compared with the standard picture of 1 inch x ¾ inch so that the area of the picture is approximately ⅙ of that of the standard picture. The film has only one perforation on each side per picture while the standard has four perforations. This has the advantage that it is impossible to misframe the picture. If it is framed at all, it must be framed right on the screen. It will be seen that five pictures on this small film occupy the same length as two pictures on the standard film. The small film, therefore, has 40 pictures to a foot whereas the standard film has only 16 pictures per foot, and while a foot of standard film lasts only one second on the screen a foot of the Kodascope film lasts 2½ seconds. The spool used in the Cine Kodak takes 100 feet of the small film, corresponding to 250 feet of the standard film, and the Kodascope projector reel takes 400 feet, corresponding to the standard thousand foot projection reel, which runs for 16 minutes (Fig. 11). The small size of the Kodascope film naturally makes its cost much less than that of standard film. It costs approximately sevenpence to take a negative, develop it, and make one print on standard film for each second on the screen, that is, for each foot of film: so that to make a standard film of 1,000 feet will cost £30. The Kodascope film will cost about a penny-halfpenny a second, so that a reel running for one thousand seconds will cost £6.

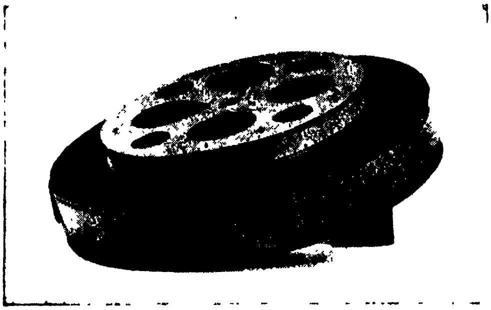

FIG. 11.—Standard reel and Kodascope 400 foot reel.

In order to get some idea of what this means to the amateur, it is necessary to remember how long a picture should be. Experience has shown that a view of a stationary object or one in which the movement is repeated, such as a waterfall or a game, and in which there is no continuity in the action should last on the screen for between 5 and 10 seconds. This may seem short, but trial shows that if a scene of this type lasts for more than 10 seconds the audience wearies of it. When taking pictures with the Cine Kodak, therefore, it is desirable to give about 7 or 8 seconds' exposure to each scene, moving the camera from one point to another in order to get variety. The cost, therefore, of a single scene taken with a Cine Kodak is about tenpence, and this compares well with the cost of taking an ordinary kodak picture, developing the negative, and making one print. On the whole, it appears as if amateur cinematography with the Cine Kodak will not be more expensive to the user than is still photography.

The film base used for making the Kodascope film is the slow burning film made from cellulose acetate. While the cellulose nitrate

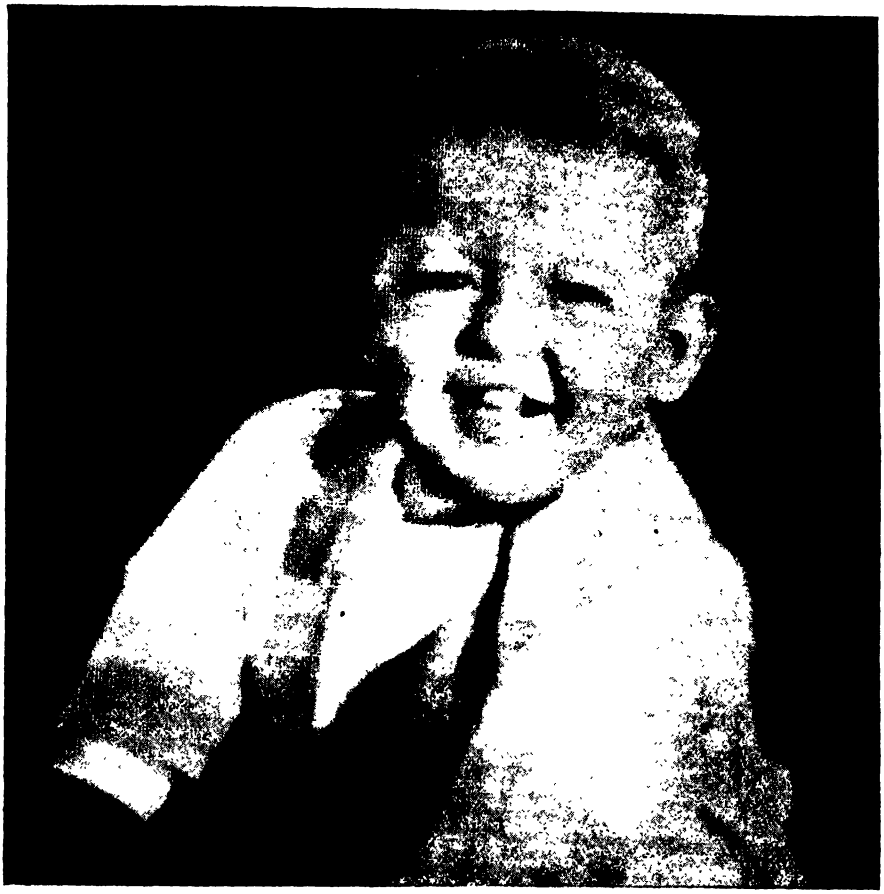

FIG. 12.– Enlargement of single small picture.

film commonly used in motion pictures is entirely safe for theatrical work where proper precautions are taken to prevent any risk of film fires and to quench a fire should it arise, the introduction of such film into the home or school is most dangerous, and one of the great advantages of using a special size of film is that it will not be possible to obtain this film in the fast burning nitrocellulose stock. For the same reason, though to a lesser degree, it is an advantage that this new film cannot be cut from film of standard size by any simple operation. Several small projectors that have been built recently have been made to take half-width film, to be obtained by slitting standard perforated motion picture film in half. While, of course, it is intended that slow burning stock only should be used for this purpose, there is always the danger that someone would be tempted to use the cheaper nitrate stock and to slit it in half for use in the narrow width. The same objection applies with much greater force to the use of projection machines taking film of standard width. It is probable that in the near future there will be a number of projectors on the market and possibly some cameras also taking the 16mm. film, so that the 16mm. size may become standard throughout the entire trade for small film used for amateur film photography just as the professional 1⅜" film used first by Lumiére and Edison became the standard for all motion picture work.

The single small pictures taken on the Cine Kodak can be enlarged, and so fine is the grain and so good the definition that the results of enlargements of these extremely small pictures which, if examined in the hand, need a microscope to see the details are of surprising quality. One of these enlargements is shown in Fig. 12.

The first equipment to be put on the market by the Kodak Company will be in the form of an entire outfit for taking and projecting the pictures. It will include the camera with its tripod and tripod head, the Kodascope with the screen, and the necessary accessories, such as a device for joining the films together. With the outfit an amateur will be equipped to take his own pictures and project them, or those taken by other people.

The introduction of motion pictures into the home will, of course, produce a demand for pictures other than those taken by the owner of the machine, and we are arranging, therefore, to supply for the Kodascope a library of films made by the reduction of standard reels to Kodascope size. We hope later to have several hundred subjects available, including scenic pictures, stories for children, and pictures of all kinds of a type suitable for use in the home. We believe that the spreading use of the motion picture at home will increase the public interest in the motion picture and will rouse the interest of many people who have not, up to the present, been regular attendants at the motion picture theatres, so that they will follow the progress of the art and will take a real interest in the development of pictures as shown in the large theatres. Just as the widespread use of photography by the amateur has been the chief contributing cause to its marvellous development in the last thirty years and to its extension to every field of human activity, so I believe the use of the motion picture by photographers throughout the world will make possible developments in the art of the motion picture that are at present undreamt of, and that the use of the motion picture in schools, institutions, and homes has a future to which the Cine Kodak and Kodascope will contribute in no small degree.

[During the reading of the paper a cinematograph film was taken of the Chairman, the Secretary, and some other members of the audience; this was immediately developed, and the result projected at the conclusion of the lecture.]

DISCUSSION.

The Hon. Stuart A. S. Montagu said that he would like to ask four questions of the reader of the paper. In the first place, was it necessary to expose the whole 400 feet of film before it could be developed and inspected? It might be very desirable for the amateur to see what he was doing. Again, was it possible to insert titles and sub-titles as was done in the case of ordinary film productions? He also wanted to know whether any means was provided for slowing down the speed of projection so as to analyse the movements, a thing which might be very useful in connection with training for sports. Finally, could the film be separated and pieces joined together?

Mr. T. Thorne Baker congratulated Dr. Mees on his paper and on the results he had exhibited. There was very little doubt that the instrument he had brought forward would place amateur cinematography on the same basis as ordinary photography had been placed by the snapshot camera. One point of considerable interest to amateurs arose. The amateur after he had exposed his film had to send it to the Company to be developed, and no provision appeared to have been made for the amateur to develop his film himself. Yet surely to a keen amateur the possibility of doing all the work himself in producing the finished result would bring considerable pleasure. Was there any chance of the amateur in the future being given the opportunity of making his own positive? Dr. Mees was further to be congratulated on the excellent way in which he had got over the difficulty of grain in the film. The fact that the least exposed grains were the smallest was one which was apparent from the researches in chemistry during recent years, and it was delightful to observe how the information had been applied in this case to make the small picture as grainless as the large one. Dr. Mees had said that such pictures as he had projected that evening should not be on the screen more than 7½ seconds, but he thought that a good many in that audience could have wished that particular scenes were shown for rather longer, and indeed in certain of the examples Dr. Mees had shown a particular picture for twice that length of time without in the least boring the audience. He feared that in insisting on a 7½ seconds picture Dr. Mees had been infected with American hustle.

Dr. Mees, in reply, said that the film used for exposing in the camera was not in 400 feet lengths. It was the film in the projector which was of that length. The film for the camera was in 100 feet and 50 feet lengths. Of course, it was necessary to finish that length before there could be any development. He did not think that such reels were too long. A 50 feet length represented a morning's work for the ordinary man in the ordinary way. In the subsequent handling and finishing of the film the cost for a short length was almost as great as for a long one. There was nothing to prevent the amateur making his titles and sub-titles. His firm could make titles very cheaply, and instead of making his titles for himself, the amateur could avail himself of that if he pleased. With regard to cutting the film, a splicing outfit was provided with the equipment, and was indeed part of the equipment, so that the amateur could join his films together as he pleased. With regard to gearing down for slow motion in order to enable the analysis of motion to be made, this would entail running at eight times normal speed, and a standard camera running at eight times normal speed would fall to pieces. His firm had not made any preparations for a high-speed camera, though they might do so eventually. But they had discovered how fast they could run this camera, and they found that they could run it at four times normal speed. It could be started and stopped more rapidly than the standard camera, and a gear could be put on in the laboratory to run four times normal speed

With regard to Mr. Thorne Baker's question, the speaker had no vision of the amateur developing his own film. It was a very difficult thing to do. Moreover, 100 feet of film was quite a serpent to play with in the dark-room. The cost of the development equipment would be at least as great as that of the camera, probably more. He could not see any large number of amateurs wanting to struggle with it. He thought that a means of development might be wanted for scientific work; he had had one or two qualms about that. If there was any demand for it, his firm would try to work out a modified reversal process, although this would not afford such control of exposure and would not be so good for the amateur. He was more concerned to provide means in any part of the globe for getting the amateur's work properly finished than to furnish the amateur with means for, perhaps improperly, finishing it himself. In his experience 7½ seconds was quite long enough for the projection of most pictures of this kind; although, of course, the pictures he had shown that evening had been selected as specially good, and in some cases the projection was allowed to be longer. If people really wanted to use more film he would be delighted, but he thought that experience would show when one came actually to take such pictures that 7½ seconds was about the limit.

THE CHAIRMAN said that that evening would be remembered in time to come as a noteworthy occasion—an occasion on which cinematography had really come into its own. He did not quite agree with the comparative sketch given by Dr. Mees of the development of photography and the development of cinematography. Photography after its invention had at least forty years in which it was chiefly run by amateurs, but in the case of cinematography the art of rendering motion quickly passed into other hands. He believed it was an imaginative Frenchman, M. Pathé, who conceived the idea of acting something that had never actually happened and using the film to illustrate it, and this idea immediately became popular, with the result that there had been enormous commercial and industrial development along these lines. He noticed that very largely in America they measured the value of a film by the cost. A million dollar film was brought out, and this was followed immediately by a two million dollar film, and so on. His own personal view was that the ordinary films on public exhibition were designed for the cure of insomnia. On looking at them he gradually felt himself sinking into a state of coma. But it now seemed possible that there would be some relief from the professional producers of film, and he was glad to hear Dr. Mees say what he did at the end of his paper, because undoubtedly all this complication, all this stage management, all this colossal expenditure, was not necessary for the production of such films as would interest a great many people, especially children. He was quite convinced that the apparatus demonstrated that evening was going to have a very great influence on the future of the cinema. One point which occurred to him was that the ordinary cinematograph production as a result of standardization of film, was current in every part of the globe. Was this sub-standard cinematograph going to have that same advantage? He would be rather interested to know whether there was any likelihood of a sub-standard becoming as international as the full-size standard. He asked the audience to accord a most hearty vote of thanks to Dr. Mees.

The vote of thanks was accorded unanimously.

DR. MEES, after acknowledging the compliment, said with regard to the standards question that his firm had already persuaded many of the firms in the United States who were experimenting on sub-standard machines to adopt this film. His firm had no objection to their making machines, provided they made good ones. He expected this to become a standard film in exactly the same way as the film for the motion picture houses.

RECONSTRUCTION IN JAPAN.

An interesting article in *Commerce Reports* gives an account of the effect of the recent disaster on Japan's economic statement, and the steps towards reconstruction which are being initiated. The greatest economic loss to Japan, apart from the appalling loss of life, is confined more or less to the material losses in and around Tokyo and Yokohama, which are officially stated to be a little less than $1,000,000,000. This, distributed over the Japanese Empire, will mean a per capita loss of only $13, which, together with the already existing national debt of Japan, will still leave the nation in an enviable position in this respect. As fully 75 per cent. of this insured value will be represented by labour in rebuilding, the increased effort of the Japanese will compensate largely for the loss.

About 75 per cent. of all the buildings in Tokyo were burned or wrecked, while the percentage in Yokohama is estimated to be even greater. The Japanese Government has already signified its intention of creating a ministry of reconstruction for rebuilding the devastated area. This bureau will be greatly assisted in its task by taking advantage of France's experiences in rebuilding the area devastated by the war. It is understood that the construction of anything but temporary buildings has been prohibited in Tokyo, pending the completion of plans and specifications for the rebuilding of the new city.

All problems pertaining to the reconstruction programme will be administered by the ministry. Such material as will be required from abroad to carry out this work will be imported by large Japanese importing houses that maintain branches in the foreign markets, or may be supplied by large foreign firms with branches in Japan. Building material will necessarily be imported in large quantities and considerable economy will be effected by the placing of large orders with individual firms having buying organisations in the United States and elsewhere. Until further notice building materials will enter Japan without the payment of the customary duty.

For several years Japan has been planning to reconstruct and modernise the city of Tokyo. The narrow, crooked streets, and the antiquated buildings were entirely inadequate, and it was recognised that such a transformation was necessary in order that the natural advancement of the city should continue. Some progress in the reconstruction had already been made, and the city boasted of many modern steel and concrete structures, which are said to have withstood the shock and are left intact. Some of the streets had also been widened, especially where it was desired to lay trolley lines. Many other streets had been designated for improvement, but the cost of tearing down and rebuilding was so great, and so many other obstacles were encountered, that the work was lagging while the necessity for improvement was becoming more pressing.

In Yokohama the situation was somewhat similar. The port facilities, while they were being modernised as rapidly as possible, were deficient in many ways, especially as regards warehousing and communication by land to the interior.

The reconstruction ministry will not be faced with any of the old objections and difficulties that handicapped progress before the disaster. The cities have been swept away as if by magic, while the inhabitants remain. The desire for modern cities has been replaced by the necessity of building cities to house the people. Their progressiveness, as well as the rebuilding programmes that have been carried out following similar disasters in other countries, makes it certain that within a few years a new Tokyo and Yokohama will be created that will be modern in every respect, and far better equipped to share in the economic progress of the Japanese Empire.

VITAL STATISTICS OF THE AMERICAN NEGRO.

Some interesting particulars of the Vital Statistics of the American Negro are contained in the Statistical Bulletin of the Metropolitan Life Insurance Company. In past years, vital statisticians have been pessimistic with respect to the American negro's chance for survival under the increased concentration of members of this race in the cities. In fact, for years there seemed to be a marked tendency toward increase in the death rate of urbanized negroes with an accompanying excess of deaths over births. This, some students contended, would lead eventually to the extinction of the city negro. But the plain facts for recent years are entirely opposed to this view, and this can best be seen from the mortality records of negroes insured in the Industrial Department of the Metropolitan Life Insurance Company. These negroes are, for the most part, urban dwellers in Southern as well as Northern communities.

Life-tables show more fittingly than do other measures of mortality just what changes occur from time to time in the expected after-lifespan of population groups. In the two years, 1911-1912, the expected lifespan for coloured male policy-holders at age ten was 41.32 years; in 1922, the expectation was 46.74 years, an increase of about 5½ years or 13.1 per cent. This broadening of the lifespan among negro males may be compared with an increase of 6.3 years or 13.8 per cent. for insured white males over the same period. Among negro females at age ten the expectation increased from 41.30 years in 1911-1912 to 46.07 years in 1922, which is a gain of about 5 years or 11.5 per cent. This is a decidedly better record than the increase of 3.8 years, or 7.5 per cent., for insured white females.

These figures show what has happened to promote the general well-being of the American negro. When the lifespan of a people lengthens by as much as five years over a decade, it is indicative of far-reaching changes in conditions of life and labour. There is no longer any room for pessimism respecting the negro's chance for survival. The members of this race have benefited decidedly and are improving their longevity prospect constantly from wider economic opportunities, and from public health measures.

The northward migration of the race in recent years has probably not had any effect, adversely or otherwise, upon the mortality rates of this insured group. In 1922, 41 per cent. of the Company's business on negro lives was done in the South and South-west, and while this figure is slightly less than that for former years, the change of residence has apparently not had any effect on the life-expectancy figures quoted above. The fact is, that North and South, the condition of the urban negro has steadily improved, and there is no indication that this tendency will slacken. While negro mortality is still much in excess of that among white persons, the gap between the rates for the two races is being closed. Tuberculosis, typhoid fever, malaria and other diseases, which were responsible for excessive death rates among negroes a decade ago, are being brought under control. This is being accomplished by the organized public health movement, and by the negroes themselves through their press and other facilities for dissemination of instruction in hygiene. The most powerful factor of all, however, is the rise in the level of well-being for the negro, brought about by better economic conditions.

THE ISLAND OF GUERNSEY.

Guernsey, which was recently visited by a party of members of the British International Association of Journalists, is one of the most interesting of the Channel Islands. The area (only about 16,000 acres) is very fully utilised, about 10,000 acres being under cultivation. It comes as a surprise to learn that in this small island there are no less than 288 miles of roads, and approximately one motor-car for every 30 inhabitants—probably a larger proportion than prevails elsewhere in the British Isles.

Industrially Guernsey is interesting for the fact that many commodities are both exported and imported. Its genial climate (frost and snow are almost unknown) has made the island famous for the intensive culture of fruit, flowers and vegetables. The interior low-lying portion of the island is practically one vast greenhouse. Land is so valuable that it does not pay to produce most common articles of food in bulk. Growers accordingly concentrate on the production of early fruit and vegetables for export, but, during the cheap season, the same produce is largely imported for home consumption. Thus the earliest potatoes (of which about 2,000 tons were exported in 1922) come from Guernsey, but they are nevertheless largely imported during the summer, and the same applies, in a lesser degree, to strawberries, raspberries and other fruit. Tomatoes are perhaps the most lucrative crop, nearly 18,000 tons being exported in 1922. In the same year about 2,000 tons of grapes were shipped abroad.

Flowers, of course, flourish in Guernsey. Hydrangeas, fuchsias and other shrubs grow in the open to immense size. Upwards of 1,700 tons of cut flowers were exported last year. It is not generally known that Guernsey also supplies considerable quantities of bulbs (chiefly Narcissus, Daffodils and Gladiolus) to growers in Holland for the purpose of enriching their stock.

The granite quarries of Guernsey also form a valuable asset. Although the trade has fallen off somewhat during recent years, 196,570 tons were exported in 1922. Most of the houses in the island are built of this excellent stone, but, as many other materials have to be imported, the cost of building is, on the whole, not particularly cheap. Mention should also be made of the small island of Lihou, which, during the war, was the centre of a valuable process for the production of iodine from seaweed. Another flourishing local industry is the preparation of tobacco and cigarettes. These, like whisky, are approximately half the price current in England. The fact that income tax is only 6d. in the £ (and local taxation and rates are insignificant), forms a strong inducement to retired persons living on their incomes to settle in Guernsey, where life is easy and pleasant. There are still people in the island who have never seen a train. The absence of railways and other inducements to hurry is no doubt partly accountable for the general tendency to "make haste slowly."

The chief scenic feature of Guernsey is, of course, the fine range of cliffs, with many delightful coves and headlands, fringing the southern coast and the south-west corner. Sark, easily reached by motor-boat, offers even grander cliff-scenery, while the nearer and smaller island of Herm has, in its shell-beach half-a-mile long, a singular scientific curiosity. There is a delightfully situated and sporting golf course and the bathing during the greater part of the year is unsurpassed.

Most people visit the Channel Islands during the summer, but the months of April and May, when the wild flowers are at their best, are in some respects the best of all, and the mild climate should also make Guernsey a pleasing autumn and winter resort.

These islands have also an intellectual interest. The geological conditions in Guernsey and Sark and their peculiar local flora and fauna are well illustrated in the Guille-Allès museum, to which an excellent library is attached. The local judicial methods, systems of land-tenure, and folklore are unique, and the isolation of the islands has led to the perpetuation of beliefs and customs of very ancient date. All such matters are the subject of ardent study by the Société Guernsiaise, and visitors who desire to learn more of the beliefs alluded to should make the acquaintance of some of its leading members.

In conclusion, the writer wishes to make grateful acknowledgment of the boundless hospitality of the Guernsey Chamber of Commerce, whose guests the British International Association of Journalists were, and of the courtesy of the Southern Railway Company in furnishing free tickets to and from the island and doing everything possible for the comfort of the party.

J. S. Dow.

THE CHILEAN SULPHUR INDUSTRY.

Chile possesses important sulphur deposits scattered along the entire Andes Mountain chain in close proximity to the numerous volcanoes that are to be found within that region. The development of these sulphur deposits, however, is not always an easy matter. At times the extreme altitude makes the work of extraction practically impossible because of the deep snows covering the ground during the entire winter and even late spring. In other cases the location of the deposits in active volcanic regions such as in Chillan, retards their development. Another handicap to the industry is the absence of roads.

From a report by the United States Vice-Consul at Valparaiso, it appears that the most important sulphur deposits in the country and those that have been developed and worked the most are in the northern zone between the Provinces of Tacna and Antofagasta. In Tacna are the Villa Industrial, Aguas Calientes, Tacora, and Chupiquina mines. These, while well inland, nevertheless have good transportation facilities. The quality of the sulphur is excellent and the mines can be operated during the entire year.

In the Province of Antofagasta are numerous deposits of good quality, the principal ones being the Ancauquilcha, Sierra Ancauquilcha, Cerro San Pablo, Carcote, and Gemelos del Azufre mines. Most of these mines are at present either idle or producing only small quantities of sulphur.

Toward the south deposits of considerable size are to be found. Despite the fact that the grade of sulphur is good, these deposits have been worked but intermittently, due to their location a long distance from the coast, within the line of the heavy winter snows, and to their lack of means of transportation. These mines are situated in the neighbourhood of the baths of El Toro in Coquimbo and in the Province of Atacama. Other deposits that are well known but have never been developed are those of Nuble (near the Chillan volcano) and Colchagua Provinces.

The oldest reliable statistics available date from the year 1887. In that year Chile's production of sulphur amounted to only 0.2 ton. From 1887 to 1902 the total output was 15,000 tons; from 1903 to 1908, 20,833 tons. From 1909 to 1919, inclusive, 115,000 tons were obtained. In the year 1918 production reached its highest point, 19,557 tons. In 1920, 13,340 tons, and in 1921 9,670 tons were extracted.

One of the most important establishments in the country produced during the year 1922 and the first two months of 1923 slightly more than 936 tons of sulphur (all of which was absorbed in Chile), divided as follows: Azufre flor (finely ground or powdered sulphur) for vineyards, 12,754 sacks, shipped to Valparaiso, San Antonio, and Talcahuano; azufre molido (ground sulphur), for the disinfection of stock, 1,219 sacks, shipped to Punta Arenas; azufre molido for industrial uses, 600 sacks, shipped to Valparaiso and San Antonio.

The gradual increase in production up to 1920 was due to the greater demand for sulphur in the manufacture of powder for the nitrate mines, to the progress in the manufacture of chemical products in Chile, and finally to increased exportation abroad. From the following figures the diminishing consumption of sulphur by the nitrate mines can be appreciated: Consumption in 1919—4,000 tons; in 1920—3,800 tons; in 1921—3,000 tons. Production was also influenced by the falling off in the demand for the product abroad; during the three years 1919-1921 exports were: 1919—6,000 tons; 1920—500 tons; 1921—300 tons. Argentina is the principal consumer, with appreciable quantities going to Bolivia, Peru and Uruguay.

GENERAL NOTES.

Carnegie Institute, Pittsburgh.—The twenty-third International Exhibition of Modern Paintings in Oils will open at Carnegie Institute on April 24th, 1924. The general method of selecting the European paintings initiated last year will be continued. Information and the necessary forms for those desiring to submit paintings can be obtained from Mr. Guillaume Lerolle, European Representative of Carnegie Institute, 14, rue Brémontier, Paris, or from Messrs. Dicksee and Company, 7, Duke Street, St. James's, London, S.W. 1.

Nigerian Lignites.—A full account is given in the current issue of the *Bulletin* of the Imperial Institute of the lignite deposits of the Southern Provinces of Nigeria, which were discovered during the Mineral Survey carried out under the auspices of the Institute. The deposits exist over a considerable area, some being favourably situated for transport. A detailed study of the lignite in the laboratories of the Institute showed that it was of satisfactory composition and calorific value. It is quite suitable for briquetting, and briquettes used as fuel in firing trials in railway engines and steamboats in Nigeria have proved satisfactory.

Flax Growing in South Africa.—As a result in the decline of flax production in Russia and Ireland, growers have been compelled to seek new sources of supply, and among these the one that promises to be most suitable for flax production upon a large scale is South Africa. An English expert selected the Western part of Cape Province as presenting the most favourable soil, and Russian seed was widely distributed to farmers for experimental purposes. It is stated that these experiments proved very successful. The growth has been very satisfactory and, according to the United States Trade Commissioner at Johannesburg, it is possible that these experiments will finally result in the opening up of a new field for South African agriculture.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

December 5.—**Arthur William Hill**, M.A., Sc.D., F.R.S., F.L.S., Director of the Royal Botanic Gardens, Kew, "The Work of the Royal Botanic Gardens, Kew." **Charles Albert Seward**, M.A., F.R.S., F.G.S., F.L.S., Professor of Botany in the University of Cambridge, will preside.

December 12.—**Sir Frank Baines**, C.B.E., M.V.O., Director of Works, H.M. Office of Works, "The Preservation of Historic Buildings and Ancient Monuments." **Sir Aston Webb**, K.C.V.O., C.B., P.R.A., will preside.

Indian Section.

Friday afternoons, at 4.30 o'clock.

December 7.—**William Foster**, C.I.E., Historiographer, India Office, "The Archives of the Honourable East India Company." (Sir George Birdwood Memorial Lecture.) **The Rt. Hon. Viscount Peel**, G.B.E., Secretary of State for India, will preside.

Dominions and Colonies Section.

Monday afternoon, at 4.30 o'clock.

December 17.—Wm. C. Noxon, Agent-General for Ontario, "Empire Settlement." The Earl of Airlie, M.C., will preside.

Papers to be Read after Christmas.

G. Albert Smith, "Cinematography in Natural Colours—further developments" (with illustrations—scenes from H.R.H. The Prince of Wales's Tour in India).

Iyemasa Tokugawa, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Sir Richard Arthur Surtees Paget, Bt., "Fused Silica and its use as a Refractory Material."

H. Maxwell-Lefroy, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle."

Percival James Burgess, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

Charles S. Myers, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

T. Thorne Baker, "Photography in Industry, Science and Medicine."

Sir Richard M. Dane, K.C.I.E., Commissioner North India, Salt Revenue, 1898-1907; Foreign Chief Inspector, Salt Revenue, China, 1913-18, "Salt Manufacture in India and China."

Brigadier-General Henry Alfred Young, C.I.E., C.B.E., late R.A., Director of Ordnance Factories, India, 1917-21, "The Indian Ordnance Factories and Indian Industries."

Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Colonel H. L. Crosthwait, C.I.E., R.E., retd., late Superintendent, Survey of India, "The Survey of India." Sir Thomas H. Holland, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, will preside.

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

F. W. Walker, "The Commercial Future of the Backward Races, with Special Reference to Papua." Sir George R. Le Hunte, G.C.M.G., will preside.

The Hon. T. G. Cochrane, D.S.O., "Empire Oil: The Progress of Sarawak."

Indian Section.

Friday afternoons, at 4.30 o'clock.

January 4, 18, February 15, March 21, May 2.

Dominions and Colonies Section.

Tuesday afternoons, at 4.30 o'clock.

February 5, March 4, April 1, May 27.

Cantor Lectures.

Monday evenings, at 8 o'clock.

Aldred F. Barker, M.Sc., Professor of Textile Industries, The University, Leeds, "Recent Progress in the Wool Industries." Two Lectures. December 3, 10.

SYLLABUS.

Lecture I.—December 3rd. Raw Materials:—Brief review of developments of the past hundred years. Basic principles revealed by this review. Present-day experimental researches, including the Mendelian Researches of the Universities of Cambridge, Edinburgh and Leeds. Colonial Experimental Research with special reference to Australian and Cape wools. Peruvian Experiments. Colonel Stordy's experimental researches with reference to Alpaca and Vicuna. Mr. Stefansson's suggestion respecting Ovibos Fibre in the Arctic Circle. Introduction of new fibres into the Wool Industry.

Lecture II.—December 10th. Processes:—Brief review of developments of the past hundred years. Basic principles revealed by this review. Recent improvements in the principles of manipulation of the raw materials. Recent mechanical developments. Prospective manipulative and mechanical developments. Distribution of the Industry:—The present distribution and the principles of distribution involved. Prospective distribution.

Eric Keightley Rideal, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University Cambridge, "Colloid Chemistry." Three Lectures. January 21, 28; February 4.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

Cobb Lectures.

Monday evenings, at 8 o'clock.

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures March 24, 31; April 7.

Dr. Mann Juvenile Lectures.

(*Special tickets are required for these Lectures*).

Wednesday afternoons, at 3 o'clock.

Dr. William Arthur Bone, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology. "Fire and Explosions." Two Lectures. January 2, 9. The Lectures will be fully illustrated with experiments.

Mrs. Julia W. Henshaw, F.R.G.S., Croix de Guerre, "Among the Selkirk Mountains of Canada (with ice-axe and camera)." One Lecture. January 16. The Lecture will be fully illustrated with hand-painted lantern slides.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY. DECEMBER 3... Geographical Society, 125, New Bond Street, W., 8.30 p.m. Sir Charles Bell, "A Year in Lhasa."

Swiney Lecture, King's College, Strand, W.C., 5.30 p.m. Dr. W. T. Gordon, "Gem Minerals and their Uses in Art and Industry." (Lecture VII.)

Alpine Club, 23, Savile Row, W., 8.30 p.m. Dr. C. Wilson, "Climbing in the Bregaglia."

Chemical Industry, Society of, at the Chemical Society, Burlington House, Piccadilly W., 8 p.m. 1. Mr. J. Allen Howe, "The Use and Preservation of Building Stone." 2. Messrs. J. J. Fox and T. W. Harrison, "The Chemical Aspects of Building Stone Decay."

Engineers, Society of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Mr. J. W. Gordon, "Railway Surveying by Photography."

Textile Institute (London Section), 38, Bloomsbury Square, W.C., 5.45 p.m. Prof. W. Davis, "Knitted Fabrics."

Electrical Engineers, Institution of, Victoria Embankment, W.C., 7 p.m. Informal Meeting. Discussion on "Electrical Apparatus for the Deaf."

Automobile Engineers, Institution of, The College, Loughborough, 7 p.m. Mr. L. Murphy, "The Misuse of the Internal Combustion Engine and Suggestions for its more Efficient Application."

Transport, Institution of, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C., 5.30 p.m. Mr. C. Travers, "Railways of To-day and To-morrow."

TUESDAY. DECEMBER 4... Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Mr. H. Balfour, "Observations on the Technology of the Nagas of Eastern Assam."

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

Marine Engineers, Institute of, 85, The Minories, Tower Hill, 6.30 p.m. Mr. J. H. Anderson, "Spontaneous Ignition of Coal."

University of London, King's College, Strand, W.C. 5.30 p.m. Miss Hilda Oakeley, "The Roots of Early Greek Philosophy." (Lecture II.)

WEDNESDAY, DECEMBER 5... University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. W. C. Berwick Sayers, "Library Classification in Modern Life."

United Service Institution, Whitehall, S.W., 3 p.m. Vice-Admiral V. H. G. Bernard "The Supply and Training of Officers for the Royal Navy."

Public Analysts, Society of, at the Chemical Society, Burlington House, Piccadilly, W. 8 p.m. 1. Mr. H. Toms, "Crystalline Bromides of Linseed Oil." 2. Mr. M. S. Salamon, "The Plea for Standardisation." 3. Mr. H. T. S. Britton, "Note on the Estimation of Chromium." 4. Mr. R. L. Andrew, "The Colorimetric Estimation of Lead in Cream of Tartar."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. J. Sexton, "Can Industry be divorced from Politics."

Swiney Lecture, King's College, Strand, W.C., 5.30 p.m. Dr. W. T. Gordon, "Gem Minerals and their uses in Art and Industry." (Lecture VIII.)

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. (Wireless Section.) Mr. L. B. Turner, "The Relation between Damping and Speed in Wireless Reception."

Archæological Institute, at the Society of Antiquaries, Burlington House, Piccadilly, W., 5 p.m. Mr. A. Oliver, "Some French Abbeys and Cathedrals."

THURSDAY, DECEMBER 6... Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1. Mr. C. K. Ingold, "The Additive Formation of four membered rings. Part III. A System of Nomenclature for Heterocyclic four membered Rings and the formation and Properties of some Derivatives of β-methylenedi-imineoxide." 2. Messrs. H. J. S. Sand and E. J. Weeks, "The Dependence of Polarisation-overvoltage on Hydroxyl and Hydrogen Ion Concentration. Part I. Polarisation-overvoltage of an Antimony Cathode in Aqueous Alkaline Solution." 3. Mr. H. King, "Stereoisomerism and Local Anaesthetic Action in the β-Eucaine Group. Resolution of β- and iso-β-Eucaine." 4. Mr. A. Green, "β-alizarin. An isomeric form of Alizarin." 5. Messrs. O. L. Brady and F. P. Dunn, "The Isomerism of the Oximes. Part XV. The supposed fourth Benzildioxime." 6 Messrs. W. E. Garner and F. C. Randall, "The alternation in the Heats of Crystallisation of the Normal Monobasic Fatty Acids."

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Mr. L. Brooks, "The Beginnings of Geographical Teaching."

London County Council, at the Geffrye Museum, Kingsland Road, E., 7.30 p.m. Major A. A. Longden, "The Modern Home."

Auctioneers and Estate Agents' Institute, 34, Russell Square, W.C., 6.30 p.m. Mr. H. Ambler, "Tithes and Tithe Rent Charges."

FRIDAY, DECEMBER 7... University of London, University College, Gower Street, W.C., 5.15 p.m. Prof. Karl Pearson, "Eugenics."

Swiney Lectures, King's College, Strand, W.C., 5.30 p.m. Dr. W. T. Gordon, "Gem Minerals and their Uses in Art and Industry." (Lecture IX.)

Philological Society, University College, Gower Street, W.C., 8 p.m. Mr. C. R. Enock, "Euphratean Origin of Man, Language and Place-Names."

Mechanical Engineers, Institution of, Glasgow, 7.30 p.m. Sir Westcott Abell, "The Mechanical Problems of the Safety of Life at Sea" (Thomas Hawksley Lecture).

(Yorkshire Branch). Leeds, 7.30 p.m. Mr. F. Clements, "The Forces of Nature in the Service of Man."

Geologists' Association, University College, Gower Street, W.C., 7.30 p.m.

Timber Trade Lectures, Council Chamber, London Chamber of Commerce, Oxford Court, Cannon Street, E.C., 6.30 p.m. Mr. P. F. Turner, "Chartering for Timber Cargoes."

Journal of the Royal Society of Arts.

No. 3,707. VOL. LXXII.

FRIDAY, DECEMBER 7, 1923.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2).

NOTICES.

◆

NEXT WEEK.

Monday, December 10th, at 8 p.m. (Cantor Lecture.) **Aldred F. Barker**, M.Sc., Professor of Textile Industries, The University, Leeds, "Recent Progress in the Wool Industries." (Lecture II.)

Wednesday, December 12th, at 8 p.m. (Ordinary Meeting.) **Sir Frank Baines**, C.B.E., M.V.O., Director of Works, H.M. Office of Works, "The Preservation of Historic Buildings and Ancient Monuments." **Sir Aston Webb**, K.C.V.O., C.B., P.R.A., will preside.

Further particulars of the Society's Meetings will be found at the end of this number.

DOMINIONS AND COLONIES SECTION.

Tuesday, November 27th, 1923; **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

A paper on "The West Indies" was read by **Viscount Burnham**, C.H., LL.D., D.Litt.

The paper and discussion will be published in the *Journal* of December 14th.

FOURTH ORDINARY MEETING.

Wednesday, November 28th, 1923: **Lord Dawson of Penn**, G.C.V.O., K.C.M.G., M.D., F.R.C.P., in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Avram, Möis H., New York City, U.S.A.
Davis, Neville Ryland, London.
Duitz, Emile A., Amsterdam, Holland.
Gray, Roland, Boston, U.S.A.
Lang, Reginald, Plymouth.
Morrow, George Leslie, Berkhamsted, Herts.
Rayner-Smith, Percy, London.
Williams, Lennard, Tilehurst, Berks.
Williams, Stephen Miller, Arkansas, U.S.A.

The following candidates were duly elected Fellows of the Society:—

Burnham, Walter Witt, London.
Jack, James, New Cumnoch, Ayrshire.
Jacques, Gilbert J.P., Ontario, Canada.
Markgraf, Miss Agnes, The Hague, Netherlands.
Peterson, President Elmer George, Ph.D., A.M., B.S., Logan, Utah, U.S.A.

A paper on "The Effect of Sun, Sea and Open-air in the Treatment of Disease," was read by **Sir Henry John Gauvain**, M.A., M.D., M.Ch., Medical Superintendent of the Lord Mayor Treloar Cripples' Hospital.

The paper and discussion will be published in a subsequent number of the *Journal.*

REPRINTS OF CANTOR AND HOWARD LECTURES.

The Cantor Lectures on "The Vulcanisation of Rubber" by **Henry P. Stevens**, M.A., Ph.D., F.I.C., and the Howard Lectures on "The Development of the Steam Turbine" by **Stanley S. Cook**, B.A., M.I.N.A., M.I.M., have been reprinted from the *Journal* and the pamphlets (price 2s. each) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2.

A full list of the lectures, which have been reprinted and are still on sale, can also be obtained on application.

MANN JUVENILE LECTURES.

Under the Mann Trust a short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, 2nd and 9th January, 1924, at 3 p.m., by **Dr. William Arthur Bone**, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology, on "Fire and Explosions." The lectures will be fully illustrated with experiments.

A lecture will also be given on Wednesday, January 16th, at 3 p.m., by **Mrs. Julia W. Henshaw**, F.R.G.S., Croix de Guerre, entitled "Among the Selkirk Mountains of Canada (with ice-axe and camera)." The lecture will be fully illustrated with hand-painted lantern slides.

Special tickets are required for these two sets of lectures. A sufficient number

to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply to the Secretary at once stating for which lectures the tickets are required.

PROCEEDINGS OF THE SOCIETY.

◆

THIRD ORDINARY MEETING.

WEDNESDAY, NOVEMBER 21st, 1923.

THE SECRETARY announced that Lord Crawford had sent an expression of his great regret that he had suddenly been called to Manchester on urgent business and would therefore be unable to take the Chair as arranged. Mr. Bernard Rackham, of the Victoria and Albert Museum, had very kindly consented to take Lord Crawford's place at very short notice.

THE CHAIRMAN said he would like to add his word of regret that Lord Crawford was not able to be present that evening. It might not be known to everyone that Lord Crawford had lately added to his numerous public-spirited activities by becoming the second President of the Society of Master Glass Painters, in succession to the late Lord Plymouth.

Before reading his address, Mr. Knowles paid a tribute to the memory of the late Maurice Drake, who, he said, had been so greatly interested in the subject of ancient stained glass, and who had made the subject his own.

The following paper was read:

FORGERIES OF ANCIENT STAINED GLASS:

METHODS OF THEIR PRODUCTION AND DETECTION.

By J. A. KNOWLES.

There is no greater enemy of all true lovers of old work and old craftsmanship than the forger. Even to those who feel nothing of the joy of possession, which is the essence of collecting, but who look to make a living, and an honest one, by buying and selling, the forger does the very greatest harm. They are very frequently his victims, whilst his productions have turned up so frequently in auction rooms that both private individuals and dealers are very shy of bidding for something which may eventually prove to be worthless, and, therefore, sometimes absolutely genuine specimens are passed over or sold for a small figure. Unfortunately, glass is a subject which is very little understood, and whilst there must be scores of people who are capable of giving expert advice on an oil painting and hundreds of others who have sufficient knowledge to exercise a very sound judgment in such cases, those who are similarly equipped with a knowledge of glass painting are comparatively few. Yet in spite of the fact that forgers, no doubt, will always exist as long as there are those who can be taken in, though I cannot in any way claim the title of "expert," I will as a practical glass-painter endeavour to show by what means forgeries are produced and some methods of detecting them.

Before going into the subject in detail it may be well to discuss the subject in its general aspects. In the first place there is an essential difference between a forgery and a reproduction. The essence of this difference lies in intention. Reproductions and copies of old work have, for example, been made for museums overseas, where it is next to impossible to obtain original glass. Such are clearly labelled and the names of the artists who were responsible for them stated as a tribute to an excellent and painstaking piece of work. They have also been done in such cases as where glass has been shivered to fragments by having cold water played upon it whilst it was heated when churches have caught fire, and where to remove the glass from the lead would spell disaster. Such a case occurred in connexion with one of our large northern churches, and the copy has preserved to us a facsimile of the original glass so exactly like the original that it would be difficult to say which was which. All such copies should be, and generally are, signed, marked and dated; whilst at the same time no attempt is made to imitate the corrosion of the glass so that they are in no way intended to take the public in. On the other hand, a forgery is an iniquitous piece of work in that it is an attempt to extort sums, and frequently very large ones, under false pretences.

Glass is a comparatively fragile* material, so that old circles where a scene, shield of arms, or what not has been painted on a single piece of glass of six or eight inches in diameter, are generally cracked across in one or two places, and these cracks have been repaired with leads in order that they may appear old. Spurious examples generally have a few cracks across them, too, but as a rule the forger cannot bring himself to cut or break them across the most interesting part, such as the head, where, as we are painfully aware, such breaks, seemingly through the sheer perversity of things, generally do occur, but he cuts or breaks the pane in such a way as to damage the subject as little as possible.

---

* The statement that glass is only *comparatively* fragile has not been made without due thought or consideration. One cannot but marvel for example that pieces of glass are frequently to be seen, such as those in St. Michael's, Spurriergate, York, of the most complicated and difficult shapes to cut and glaze, which have remained intact for hundreds of years without a break or crack in them. Other examples are the quarterings of the shields frequently to be seen in England and France where the charges, three fleur de lys, have been let into a piece of blue glass in which three lozenge-shaped holes have been drilled and cut to receive them, yet the glass has remained intact to this day.

Doubtful examples should, if possible, be taken out of the lead and the breaks examined. If the edges of the various pieces do not fit together as exactly as the two halves of a biscuit which has been broken in two, the specimen is spurious. The edges should also be examined to see whether a diamond has been used to cut the circle up into pieces in imitation of breaks. This can be seen with a good lens, as a diamond slightly scratches and chips the surface, whereas a break is perfectly clean. If the breaks or cracks are many and it has been necessary at some earlier period to re-lead the panel, the pieces may, of course, have been grozed down by chipping off fragments from the edges with the pincers in order slightly to reduce each piece in size so as to make room for the core of the lead. Thus, for example, in a panel, originally of a single piece of glass one foot in diameter, if there are eight cracks across it, and the core of the lead measures 1/16th of an inch ; half an inch would have to be taken off the glass somewhere in order to keep the pane its original width. The various pieces of such a pane, therefore, would not fit exactly together when taken out of the lead, as each one had been more or less whittled down. But old glass is never perfectly flat, but always more or less reamy, wavy, undulated and bubbly. It is, therefore, necessary to notice carefully whether the waves, bubbles and undulations are continuous from one piece to another, such as one would expect in a single piece of glass which had been broken, and that the panel has not been formed of six or more different and distinct pieces of glass in which the waves and bubbles do not pass naturally from one to the other, but go off in different directions.

Forgers even buy up panes of glass from old windows and paint on them so that, though the glass may be comparatively old, the painting is new. But the difficulties of obtaining glass of this kind except in the form of diamond panes or "quarries," are great, and of any size next to impossible ; for formerly windows were leaded in panes which did not average more than six by four inches in size, and much of the glass used for this purpose was not the fine glass of Lorraine, such as the old glass-painter set such store by for painting on, but the Dutch and German glass, or in England, Newcastle glass, which was of an ashen tint and very reamy.

The outside edges of the pane of glass should also be examined to see if it has been cut to shape with a diamond. It might, of course, as previously mentioned, have been trimmed down at some comparatively recent period, but if there is no reason to believe that this has been done, a straight clean cut, such as is obtained by the use of a diamond or a wheel, gives away the panel at once, and any glass which shows this, and which is supposed to belong to a period anterior to 150 years ago, is extremely likely to be modern. I am quite aware that a diamond is mentioned for cutting glass in the fifteenth century Bolognese M.S.,* also that Vasari tells us William of Marseilles employed an emerald for the same purpose. But that these were not used in Jost Amman's time, 1539-1591, is shown by his drawing of a glazier at work. Moreover, these early diamonds cannot have been of much practical value and were probably the cause of the breakage of more glass than they cut. The essence of the process is in the setting of the stone, the cutting edge of which must be in a straight line with the line being cut, otherwise a scratch and not a cut results. The early diamonds mounted in pencil form, which could be twisted and turned in any direction, would do very well for writing on glass ; but would be of little use for cutting it. Le Vieil* tells us that it was not until about 40 years before his time (*i.e.*, about the year 1730) that diamonds were first mounted in a flat ended handle, whilst Shaw's diamond, where the cutting edge is trued up parallel to the edge of a steel block, which when held against the lath causes the diamond to make a clean and continuous cut, was only patented as recently as 1815.

---

* Printed in Mrs. Merrifield's *Original Treatises on the Arts of Painting.* Vol. II.

* *Art de la Peinture sur Verre.* 1774.

Before a really practical diamond was introduced and regularly employed, glass was first roughly shaped with a hot iron and then nibbled to the exact form desired with a grozing-iron. This was a little iron instrument like a small lath or ruler with a notch in the edge, similar to the notch still to be seen in the end of the modern cutting wheel, which is used—though perhaps very rarely, as a pair of pliers does the job much better—for breaking off small strips which are too narrow to be gripped by the fingers. The grozing iron was worked on the edge of the glass so as to break off little chips. The edge of old glass, therefore, is always slightly toothed or jagged. To imitate this, which is such an elementary fact that it is known to all imitators, the pliers are employed. But the result is not quite the same. If we examine the edge of a piece of glass which has been cut in the old way, we see it has a sharp chisel edge, the edge being to the upper or painted side of the glass. But the pliers are very liable to take chips off both the upper and the lower surfaces of the glass, for both surfaces are gripped equally between the jaws.

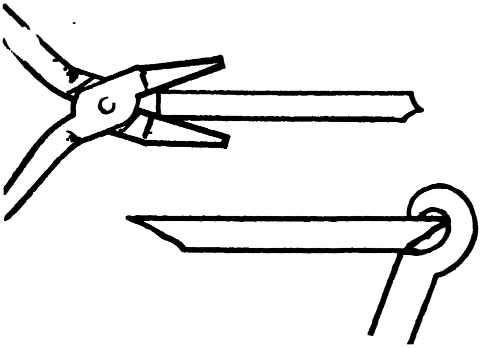

FIG. 1.—METHODS OF SHAPING GLASS.

Modern, with Pliers—Chips break away from both upper and lower faces of the piece.

Ancient, with Grozing Iron.—The edge of the glass is chisel shaped.

We will now leave the question of these panes of glass painted originally on one single piece, and turn to panels of larger size, such as are made up of a great number of pieces of glass of many different colours, as in the case of church windows.

As an aid to determining whether or not a glass painting is a forgery, a thorough knowledge of the technical history of the art is very important, for it is in this and not in dexterity of hand that the forger most frequently gives himself away, through not knowing at what periods the various improvements in the material and methods of working were introduced. A glass painting which, for example, shows the use of yellow stain before the beginning of the fourteenth century, is in the highest degree likely to be a forgery, for the earliest known example is dated about the year 1310.* Specimens presumably earlier than the fifteenth century which show jewels fluxed on or holes drilled and pieces inserted are as likely as not spurious. Glass which purports to have been executed during the fifteenth century, but which shows the use of enamels, is almost certainly a forgery. The use of acid cannot appear before the seventeenth century, and even then would be open to grave doubt; also the use of a pink glass which owed its colour to gold. Panels of church windows which pretend to belong to the second half of the seventeenth century, yet which show a profuse use of coloured glasses, are, doubtless, fakes, for in 1636 Louis XIII. destroyed all the glass factories of Lorraine, and thereby made coloured glass for church windows practically unobtainable. About the same time the secret of making ruby glass was lost, and though it appears again once or twice later, it was not in general use till after its re-discovery in 1826. No panel which contains green glass which, on analysis, proves to have been made from chromium oxide can be earlier than the eighteenth century as that metal was only then discovered by Scheele the chemist. Kilns with separate trays with but one layer of glass on each, which system enables the enamel to be fired up to a bright and glossy surface, were not introduced till 1758, and nearly fifty years later Peckitt, of York (1731-1795), was still using the old way of a pan filled to the top with alternate layers of glass and whitening. Machine-made rolled cathedrals, blown Norman slabs, and coloured sheet glasses are no older than the nineteenth century, as also are anbittie and sanded sheets.

I can well imagine some eminent counsel after much midnight oil and study of the Encyclopædia Britannica, making great play with the above conclusions, and showing to the confusion of a witness that they are quite wrong by pointing out that "fluxed on" jewels are mentioned by Theophilus, a writer of the twelfth century, that enamels were used on hollow ware for centuries before the year 1500, and that Claud of Marseilles, before the beginning of the 16th century, painted a window in enamels for the study of the French Ambassador at Rome. That acid is described in the fifteenth century Bolognese M.S., and a red derived from gold was probably known to the Saracens, and is also described in the MS. previously mentioned more than two hundred years before its reputed inventor, Andrew Cassuis the younger, lived. All this is perfectly true, but it does not prove that any of these things came into general use, or, indeed, that any specimen of them is known in any public or private collection before the times mentioned above.

---

* The Peter de Dene window in the Nave of York Minster.

THE GLASS.

The painting of a forged panel may have been so skilfully executed as to deceive an expert. But unless the glass upon which it has been done exactly corresponds in every particular with glass of the corresponding period of that to which the forgery pretends to belong, it must be rejected. The various characteristics which it must possess are many, and the difficulties of finding glass at the present day which will agree with all of them are great. The material on which the painting has been done must agree in

(i) Thickness.
(ii.) Texture.
(iii.) Wavyness.
(iv.) Tint.
(v.) Ability to stain without "metalling."

(i.) Thickness. As a general rule all ancient glass is thinner than modern. It is perfectly true that the mediæval workers were fully alive to the value of substance in glass and they also knew perfectly well that thick glass tones and filters the light as it passes through it better than thin glass does, even if the two are exactly equal in tint. But they were not always able to obtain it. Inigo Jones complained that Sir Robert Mansell, who tried to corner the glass industry in England during the seventeenth century, made very thin glass, and long before this, in 1485, at Toledo, we read that the cathedral authorities handed Master Henry the glass-painter a sum of 150,000 "maravedis" and told him "to proceed to Flanders or any other part he may desire where good glass is to be had (of white, blue, green, ruby, purple, yellow, and blackish (*prieto*) colours) and *equal in thickness to the sample which he bears*, and bring us thence such quantity as he has need of for the windows of our cathedral."* But to produce a sheet of glass of both large size and of considerable substance requires a large gathering of metal, and a strength of arm and skill in manipulation which the old glass makers were not equal to. Their glass, therefore, was made in both smaller and thinner sheets than ours is. Most of the glass after the fifteenth century was very thin indeed. In speaking of modern glass I am, of course, referring to modern "antique" glass, which is made purposely for stained glass work. That made in England at the present day is undoubtedly the finest in the world. Its thickness gives it a tone and quality which is unequalled by any other, so that glass painters from all over the world send for it for their best work. But this very quality renders it useless to the forger, who has, therefore, to use foreign antique or what are known as sanded, specky, anbituie, and tinted sheet glasses.

(ii.) This brings us to the question of texture. It is very difficult to lay down any hard and fast rule on these matters, but generally speaking, modern antique, and especially that made in England, has more bubbles in it than the old. These are purposely left in the glass as they make it more brilliant. But in glasses which are intended to be used for painting heads upon, bubbles are out of place and another means of obtaining brilliance is resorted to. The marver upon which the bulb of metal (*i.e*,, glass) is rolled before it is blown has lines upon it and these lines appear on the back of the sheet of glass and make it shimmer. This is never seen in old glass. Sanded sheet is formed by sprinkling sand on the floor of the kiln in which the cylinders of glass are flattened out into sheets. The particles of sand cause depressions in the surface and some of them adhere to the glass itself. This, too, is an impossible feature in old work.

(iii.) Though old glass may appear perfectly flat in small pieces, it is nearly always wavy and cockled on the back. This is particularly to be noted in circles and so forth of five or six or more inches in diameter upon which emblems and similar designs were painted. This was caused by the inability of the old glass makers to rub their glass down to a perfectly level surface in the flattening kiln, as is done nowadays in the manufacture of large sheets of glass, such as are used for framing pictures and for windows in houses. This only applies to such ancient glass as was produced by the "muff" process, which was formed from a large cylinder of glass which was slit down the side and opened out into a flat sheet. Old, as well as modern, "crown" glass, which consists of a circular sheet produced by whirling, does not suffer from this defect, as it has not to be flattened like the muff. To simulate the cockling and waviness of ancient muff glass, imitators are in the habit of heating it in the kiln on a tray on which the whiting has not been evenly spread, but has been left in lumps and ridges. The glass is heated to softness when it sinks down into slight hills and valleys similar to the old.

---

* *Documentos Ineditos para la Historia de las Bellas Arte en Espana*, by Zarco del Valle.

(iv.) Tint. Although the use of manganese as a decolorizer was understood and constantly employed, a perfectly colourless glass is never seen in old work. In the mediæval period, whilst greenish tinted glasses are frequent, after the fifteenth century they should be regarded with suspicion, as the old glass-painters greatly favoured the glass of Lorraine for their work on account of its valuable staining qualities, and this glass was slightly yellowish in tint.

(v.) Ability to stain. Whereas modern glass is almost invariably a sodium calcium silicate, analysis has proved that the old was almost always a potassium calcium silicate. In untechnical language, where the old workers used potash as the source of their alkali, we use soda. This fact has a very important bearing on the subject of forgeries, for there is an enormous difference between the way in which a soda-lime glass takes the yellow silver stain, and one in which the alkali employed in its manufacture is potash. For, as Mr. Noël Heaton pointed out in paper read some years ago before this Society,* the stain on a soda-lime glass is not equal to that which is communicated to a potash one. The modern glass also, in staining, very frequently "metals," *i.e.*, if you look on the back of a piece of modern glass where the yellow stain has been applied, it shows as a nasty opaque mustard yellow. Now, I do not mean to say that this effect is *never* seen on old glass, as I have a fragment in my possession which is undoubtedly ancient and yet shows this defect, but it is very unusual indeed, and in this case is only due to the fact that the glass has been so greatly over-fired as to be almost melted.

THE ENAMEL.

So much for the glass itself. We next come to the question of the enamel with which the glass has been painted, and by "enamel" I do not mean coloured enamels. These we will discuss later—but merely the opaque brown, red or black pigment which is used for painting the outlines and giving the various shades and tones of the painting. I will not go into the question of the composition and characteristics of the opaque enamels and their variations at different periods in minute detail to-night, as I fully discussed the subject in a paper read before this Society some years ago, to which I would refer those who wish to pursue the subject further.* As I there pointed out, the colour of the enamel of different periods seen by reflected light can roughly be classified as follows:

12th and early 13th centuries	Black.
13th, 14th & 15th centuries	Purple or red.
16th to 18th century	Black.

When an ancient glass-painting is held up to the light and the enamel is judged by transmitted light, it varies in what little amount of colour it imparts to the glass from a rich warm brown to a cool black. It, however, never suffers from a defect which is very common, though by no means universal, with modern glass-painting enamels, and that is "foxiness." What glass-painters term "foxiness" is a peculiar reddish cast communicated to the painting, to be seen when it is viewed at an angle instead of from a point directly in front, which is caused by a partial reflection of light from the particles of metallic oxide of which the enamel is made, some of the light passing through the panel and some being reflected back from it. Here, for example, on the screen are two forgeries of 16th century medallions, which show this. Again, in a genuine example of ancient work the traced lines must be perfectly opaque where it was so required that they should be without the line having had to be loaded with enamel in order to achieve this result, and thereby stand up above the rest of the surface of the painting. Generally speaking, the modern enamel is greatly inferior in density to the old, and the lines frequently are semi-translucent instead of being perfectly dense and absolutely opaque and, therefore, black.

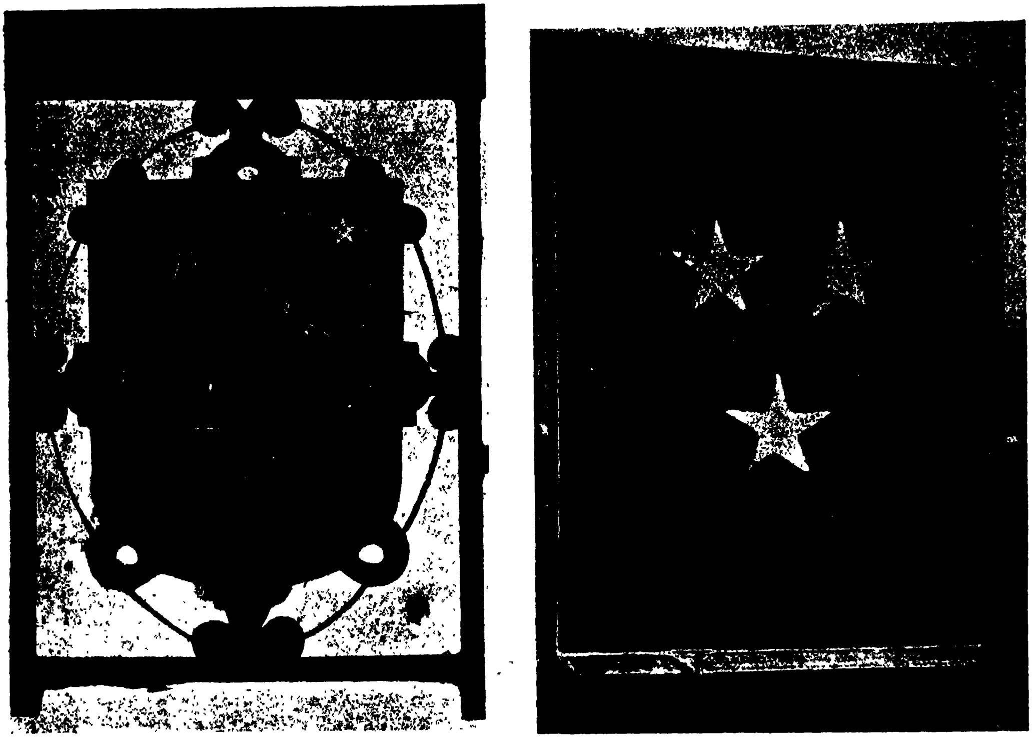
* Technique of Glass-Painting in Mediæval and Renaissance Times. *Journal of the Royal Society of Arts*, May 15th, 1914.

The old enamel, either from atmospheric influence or from insufficient firing, frequently chips off. Winston, the great authority on glass, states that he never came across an old example which could not be scratched off with a knife, and though it would be best to accept this statement with reservations, it is certain that the old enamels are never fired down as tight as the modern. Renaissance glass-paintings are particularly liable to be scratched, owing to insufficient flux in the enamel and not enough heat. The chipping of the mediæval colour in inscriptions and so forth is imitated by moistening the colour, which is held to the glass with gum alone, with an old creased and ragged wet chamois leather pressed against the glass. When this has been lifted off it brings some of the outlines and painting with it, and gives a fair imitation of the real thing.

COLOURED ENAMELS.

We have already discussed the brown or black opaque enamel used on the front of the glass to give the outlines and shading; we will now consider the coloured transparent enamels—blue, red, purple, etc.—which are generally applied to the back of the glass. As a general rule it may be laid down that except in some few exceptional cases that one occasionally comes across, the old enamels were never equal in brilliancy and transparency to those of the present day, and especially to those modern enamels of Continental origin. All this favours the detection of frauds, for most of the forgeries of the present day being made on the Continent, the producers of them employ enamels of French or German make, which, no matter how superior they may be to the ancient ones, do not match them nearly so well as English enamels do. The ancient enamels were very hard. They were, moreover, not laid on a tray in the kiln, but were fired in a pan filled to the top with whiting and glass in alternate layers one above another. They did not, therefore, fire up bright, as the contact of the enamel with the lime or whiting prevented this. At most they have but an eggshell gloss on the surface, and this was in most cases confined to the blue. Modern Continental enamels, on the other hand, are very soft. So much so that if any whiting comes in contact with them when they are being fired, they are ruined as the whiting sinks into the enamel and sticks tight to it, rendering the surface perfectly opaque. They have, therefore, to be fired on trays in the kiln, and they come up with a bright glossy surface equal to that of the glass itself. Some two or three years ago the writer saw nearly a score of panels offered for sale as antiques in a shop in Cologne, which could be condemned at a glance for this reason alone. The English enamels are much harder, they are, therefore, more difficult to fire, and the colours are not so brilliant, but the forgers of glass are not generally aware of this fact. In seventeenth century work, such as heraldry, where the enamel has been applied thickly as it had to be, and in large and broad masses, the surface is generally covered with minute fissures and cracks caused by the co-efficient of the contraction of the enamel not being equal to that of the glass to which it has been applied. On turning the panel over and looking at the enamel through the glass, we see that it has crazed the surface of the glass like frost forms on a window pane in winter. In some places the surface of the glass has given way and the enamel chipped off, bringing the glass surface with it in the form of shell-like flakes. This form of decay looks at first sight as if it would be very difficult to imitate. Yet though I cannot say I have ever seen an example where this has been done, it is in reality very easy indeed to do, and it is well, therefore, to be on one's guard as it is quite possible that an example might turn up some day. This process of decay is exactly the same as that which is artificially produced in the form of decoration known as chipped glass, which is frequently to be seen used on plate glass in doors and so forth in modern shop fitting. The letters or ornament are left clear, whilst the ground is covered with shell-like forms on the surface of the glass itself. This is done by having the parts required to be chipped sand-blasted. White acid will not



Enamel Cracked, bringing away the surface of the Glass.

FIG. 2.—Seen from inside. FIG. 3.—Seen from outside.

do, the object being to obtain a coarse roughened surface. This having been done the whole of the glass is given a coat all over of thin strong glue and allowed to dry in the air. A second coat is then applied and when that is dry a third in like manner, and allowed to dry naturally. The sheet of glass is then placed near some hot water pipes or in front of a fire. The glue then begins to contract and on the polished surface where the sand blast has not been applied, it flakes off, leaving the glass untouched. On the roughened surface, however, it has such a hold, and the contraction is so enormous that it tears flakes out of the very substance of the glass itself, forming a shell-like surface or pattern. It is easy to see how this might be applied to the imitation of the surface of glass from which the enamel has flaked off by having the part required sand-blasted and flaking it with glue, afterwards applying enamel to the surrounding portions. As will be seen by the slide, which is a 17th century glass-painter's assay piece on which he has tried his blue enamel in order to get the right quantity of flux, the crazing of the surface of the glass where the enamel has chipped off is not always the same. Sometimes it is in large cracks and flakes as in the bottom example, at other times it appears as a fine granular or stipple effect. This latter form can be imitated by means of acid, in exactly the same way as the form of decoration, which is known as stipple acid, is produced on plates and which is frequently used in conjunction with chipped glass and white acid in order to obtain various forms of surface in embossed work. The parts not intended to be treated are coated in the usual manner with Brunswick black. The plate is then put in an acid bath of equal parts of hydrofluoric acid and water and powdered mica sprinkled all over it. The acid attacks the glass unequally, being partially prevented from doing so by the flakes of mica, and a stippled effect is produced.

TECHNIQUE OF THE PAINTING.

We now come to the important question of the technique of the painting or "handling," as it is termed in oil painting. It is safe to say in this connexion that a whole book might be written on this subject alone, and then all would not have been said. It is, therefore, hopeless to attempt to treat of it at all thoroughly within the limits of a paper such as this and all that can be done is to lay down one or two main points of guidance. As regards mediæval glass the chief characteristic of glass of this period is the tracing. Though there was much inferior work produced it would be a matter of the utmost difficulty to imitate the freedom and the endless variety of width in the traced lines in the best old work. These sometimes vary from three-sixteenths of an inch or more in width at one end and then taper off till they end as fine as a hair. At the same time the utmost density is kept throughout. Most modern traced lines have blunt points, whilst but few modern enamels can be found which "work" well under the brush and yet keep their opacity when fired.

There is one characteristic of technique which glass of all periods from the earliest to the latest must possess, and it is this. It must never have been passed through the kiln more than once. At first sight it may seem next to impossible to prove whether this was done or not, but it can generally be determined with a tolerable amount of certainty by close examination of the high lights and lines which have been removed with the pointed end of a stick or a quill. In old work the traced lines and outlines were painted on first. The darker shadows were then washed in and removed where not wanted. Another wash was then applied to give the middle tones, and, finally, a thin wash over the whole surface of the glass, out of which the highest lights were taken with the quill or stick. In some places these have removed not only the three (or less) coats of shading colour, but the outlines as well, proving that there was nothing fired on up to that stage of the painting. One occasionally comes across cases where the stick lights pass under

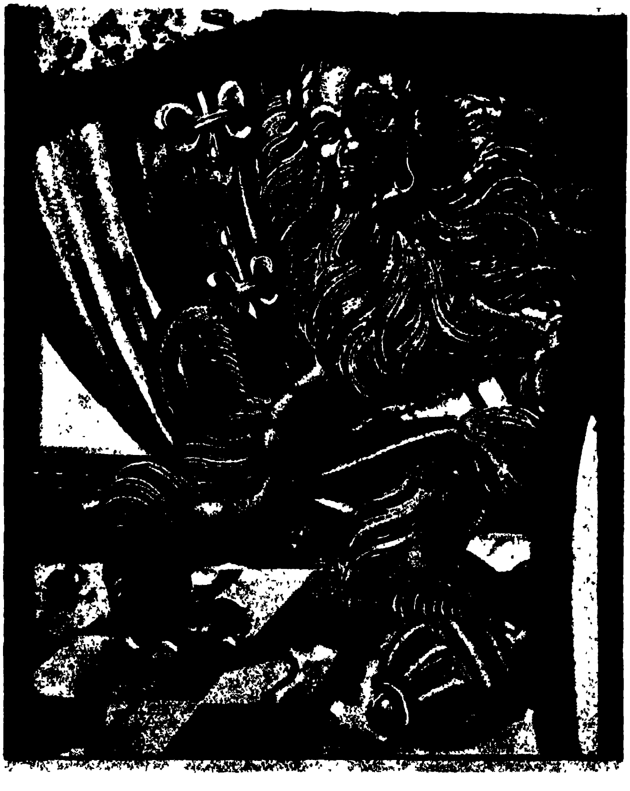


FIG. 4.—Swiss Heraldic Lion.

Strokes taken out with the quill in the mane pass through both traced lines and shading, showing that the work was done at one firing.

the outlines. These, however, are not the main outlines of the drawing, but were embellishments, such as diapers, patterns, etc., which have been painted on freehand last of all.

The only exception to this rule that one is likely to meet with, is in the case where blue enamel has been applied on the back over yellow stain so as to form green. In this case the painting on the front and the yellow stain were done at one fire, and after the superfluous stain had been cleared off the blue enamel was applied and burnt at a separate fire. It is, however, always dangerous to dogmatize in these matters. I should not be at all surprised if some day an undoubtedly authentic specimen of ancient glass turned up which showed undeniable evidence of having been fired more than once and the painting carried further before the glass went into the kiln a second time. One has always to make allowances for such cases as where an artist worked in some place far removed from others of the craft, or for the work of amateurs or beginners.[*]

The more one studies a subject such as stained glass, not from the too frequently narrow point of view, but in all its various aspects—technical, historical or what not the less one is surprised at anything. As I recently showed, for example, in a paper read before the Society of Architects,[*] there is every reason to believe that the east window of St. Margaret's, Westminster, is a re-painting by an eighteenth century artist on the top of early sixteenth century work.

One other point as regards technique. All available documentary evidence proves, and the closest scrutiny of ancient work goes to show, that oil was never used as a vehicle for painting. It was all done in water from the first traced lines to the last wash. This can to some extent be proved by an examination of the strokes removed with the pointed stick or quill. The ease and facility with which they have been taken out shows that the enamel was only lightly held to the glass, whereas had oil been used the stroke would show a gummy edge, the enamel piling up in a fatty ridge of colour. Were the traced lines done in oil, this dries hard so that the quill or stick, instead of passing through them with ease, jumps over or only partially scratches a way through.

ABRASION.

Ruby glass has always been manufactured (and at the present day still is, except in one or two very exceptional cases) in a different way from the other coloured glasses. Instead of the sheet being coloured all through, the red lies in a thin film on the surface like the gelatine film on a photographic plate, the colourless glass beneath merely acting as a support. This peculiar method of manufacture enabled glass-painters to obtain various coloured effects on the same piece of glass by removing the red film where required and applying coloured enamels or yellow stain to the colourless glass beneath. This is nowadays done by applying a protective varnish, such as Brunswick black, to the parts which it is intended shall not be removed, and afterwards placing the glass in a bath of diluted hydro-fluoric acid which eats away the exposed portions of the red film and leaves the ground beneath. In this method the acid eats straight down, leaving the untouched portions which have been protected by the resisting varnish with perfectly straight and vertical edges. It is a great temptation to the forger to use acid, on account of the speed and ease with which it can be employed, but the edges of the film should be examined and if they show that acid has been employed, the piece should be regarded with the gravest suspicion. Before the use of acid was put on a practical basis, or until a still later date when its preparation and use became common

Restaut, a lawyer and amateur glass-painter of the eighteenth century mentioned by the same author.

[*] *Journal of the Society of Architects*, April, 1922.

property, the red film had to be ground away with a grindstone or with either a copper wheel or an iron instrument and some abrading material such as sand or emery. It is obvious that it is impossible by such a method to leave a sharp clean edge. The edge of the film was always either ragged or showed in section a small arc of the circumference of the wheel which had been used for grinding, and this edge had to be covered up with a traced line; otherwise, instead of there being a sharp line of division between white and colour, the one faded into the other, and the effect was blurred.

The traced line, however, does not prevent the edge being tested to see whether it is perpendicular, as it is so excessively thin. On the contrary, the depression, which is saucer shaped when the wheel has been used, can easily be felt with the finger tip. In old work it was not generally polished after being ground out, but remains rough like ground glass.

The reputed inventor of acid for eating away glass was Henry Schwanhard, who is said to have discovered it about the year 1670. Glass cutting is also said to have been invented by Caspar Lehmann, who died in 1622. As likely as not, both these artists are given far more credit than is actually due to them, and their so-called discoveries were, no doubt, little more than improvements, for an acid or "water for cutting glass" is described in the fifteenth century Bolognese MS., and Eraclius, a writer of the thirteenth century, gives a perfectly practical account of glass cutting on the wheel. Moreover, we know that the latter process was well known and regularly employed throughout the whole of the mediæval period for piercing holes in glass for the insertion of jewels and charges on shields of arms. But the case of the use of acid is different, and we must not forget that there is an enormous difference between a process which is merely in the stage of a chemical experiment in a laboratory and the same thing placed on a commercial manufacturing basis. Photography, for example, started as chemical experiments by scientists, it was next known as a secret, and finally understood and worked by all. Fluoric acid was similarly a closely guarded secret known to few in 1721, it was imperfectly described in 1725, and the correct method of producing it was not known until Scheele, the chemist, published it in 1771, whilst long after this glass painters, such as Peckitt, of York, continued the use of the wheel with which process they were more familiar. It is, therefore, necessary to be on one's guard where examples of glass painting, even after the year 1670, shew the use of acid. I have in my possession a circle which I believe is an early example of the use of acid, but such a piece is well-nigh unique.

CORROSION.

Old glass is frequently corroded. Many people think that a piece of glass cannot be old if it is not corroded or pitted; but this has nothing to do with age. Here, for example, we have two heads from the same subject, viz., the Coronation of the Blessed Virgin, in St. Helen's Church, York. The one in a bad state of decay, the other not touched. They are both of the same age and have both been subject to the same atmospheric conditions, yet the one is preserved whilst the other is in an advanced stage of decomposition on both sides. The causes of decay in glass are nowadays well understood, but this is not the time to discuss them as the whole subject has been thoroughly treated in a paper read here some time ago.* But amateurs and novices in collecting are not satisfied unless signs of at least incipient decay are present, so that the forger is prepared to supply the demand.

One form of decay to be seen in old glass is an iridescent film on the surface of the back of the glass. This can be imitated in many ways. It can be done by the method by which the articles of iridescent glass ware to be seen in the shops are produced, viz., by the deposition of metallic tin upon the surface of the glass heated in the kiln by means of the fumes of stannous chloride. But this can be detected. Actual iridescent decay by corrosion can be artificially produced by dilute hydrofluoric acid, as every glass-painter knows who has negligently left the acid bottle in too close proximity to a bin of glass. The same result can be obtained by heating the glass with hydric chloride in an hermetically sealed receptacle.

The commonest form of decay is pitting where the back of the glass is covered, to a greater or lesser degree with holes which vary from the size of a pin head to a crater half an inch or so in diameter. These holes, which before the centre actually

---

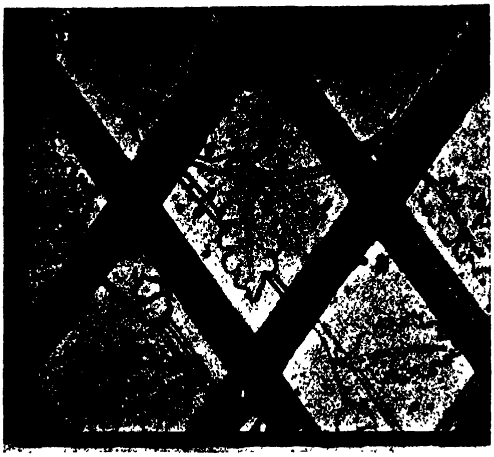

Fig. 6.—Imitation 14th Century Quarry Work.

Examples of spots of colour splashed on the glass to imitate corrosion by pitting.

falls out so as to form a pit, appear as small round black spots, are imitated by "spattering." This is done by sprinting enamel on to the back of the glass by drawing the finger across the hairs of a tooth brush filled with colour, in the same way that black and white artists produce certain shaded effects in the backgrounds of their drawings. This rather crude form of imitation can be easily detected by anyone who is conversant with the process by which it has been produced. Another method of ageing frequently employed in quarry work in order to imitate the rich brown patina which most mediæval glass has, is to apply an unequal coat of brown enamel to the back of the glass, shading it darker towards the edges to imitate the dirt which collects up against the leads. Before the glass has been fired the enamel is only lightly held with gum mixed with the enamel. When this coat of enamel has been allowed to dry, the glass is lightly spattered here and there with clear water sprinkled from the hairs of the tooth brush, or by the operator spitting on it through the closed lips. The glass is again allowed to dry and is then rubbed lightly with the tips of the fingers when holes appear where the splashes of water have been, the dry colour around each spot having acted like blotting paper and sucked the gum out of the wet spots. This, whilst it gives an antique look and might deceive the unwary, would never take in anyone who has studied glass to any extent, for the result is totally unlike the effect of corrosion, which appears as dark spots on a light ground, whereas by this method the reverse is the result. Actual holes can be produced by drilling, but a microscope will at once detect the imposture. As can be seen in these examples of large pits, which are of such size that a lens is not necessary to examine them, the formation is like that of the crater of a volcano, and such an effect cannot be imitated by drilling.

Sometimes old glass has corroded, not into round holes, but into lines caused by the unequal mixing and only partial vitrification of the hard and soft materials of the glass mixture, such as sand, lime, and alkali. The resultant glass, when it has been formed into a sheet by the "crown," or whirled sheet method, consists of lines of hard and soft metal of different densities invisible to the eye, but, nevertheless, existent in the glass. The soft parts corrode, whilst the hard parts do not. The lines of corrosion generally appear as arcs of concentric circles, of which the "punty" mark (or knob of glass in the centre of the sheet by which it was attached to the "punty" or iron rod on which it was twirled during manufacture) forms the centre. This could be imitated by the use of hydrofluoric acid and a resist, such as Brunswick black, painted on the glass in imitation of the corrosion. Such a sham, if well done, would be very difficult to detect. In cases, however, where the glass has corroded in lines and not into round holes, the glass should be closely examined with a lens to determine whether it has been made as a whirled circular sheet with a knob of glass in the middle, (*i.e.*, crown) or as a cylinder slit down the side and flattened out into a rectangular sheet (muff). This can be seen by the direction of the bubbles. If these run in straight lines parallel to each other, the glass was "muff;" if, however, they are in concentric and ever-widening circles of which the knob in the middle of the sheet formed the centre, and the elongated bubbles look like ships racing round a buoy, the glass was "crown" and the lines of corrosion must follow the same direction and not, so to speak, cut across the "grain."

Crown glass, however, is rarely corroded. Being opened out from a round globe into a flat sheet by twirling as a maid twirls a mop, after having been softened by the heat of a furnace, it has not to be rubbed down on to an iron plate to flatten it and so, as it never comes into contact with anything during the process of its manufacture as "muff" glass does, it receives a highly polished surface known as "fire finish" and this seems to help it to resist corrosion.

But though muff glass may not be actually corroded, the surface is nearly always slightly dulled.

To imitate this dulling on the back, the glass is generally given a very thin matt of black enamel. Sometimes the surface has been dulled by laying the glass on an iron or asbestos sheet in the kiln and over-firing it so that it not only is deadened, but runs into pinholes, which look like incipient corrosion. This, however, would not deceive a glass-painter, who is generally only too familiar with such accidents occurring to his work through the negligence of the kiln-man when soft glasses are being fired.

For some reason or other, which has not been as yet fully explained, the yellow stain, which is applied always to the back of the glass, protects it from corrosion, so that pitting rarely manifests itself in the parts of the glass stained yellow. If pit holes do appear they should be regarded with suspicion, as they may have been produced by spattering with paint, or the piece painted on may have been, *e.g.*, an old quarry already corroded naturally so that though the glass is old the painting on it is new.

Corrosion marks appearing in the yellow stain led to the detection of a clever forgery some time ago. Though well done, further examination showed many more of the usual characteristics. The piece was "broken" in the usual way so as to damage it as little as possible and a piece of patch inserted. The glass was too thick; it was perfectly flat on the back without any cockling, and had a bright and highly polished surface, but the bubbles showed that the glass was muff, not crown. The brown enamel was heavily fluxed and had fired down very snug to a bright, shiny surface, and was very transparent, pointing to the use of foreign enamel and a modern gas-kiln, where the glass is fired face up and a single tray at a time, not buried in whiting in a pan as the ancient practice was. The glass had not been outlined first and afterwards shaded, but the reverse process adopted, for the stick-lights passed *under* the outlines in several places. Lastly, the corrosion appeared on the *front* and not on the back and under a lens showed as black dots grouped in a regular pattern of six or eight together in small square patches, showing that they were produced by some artificial method.

SWISS GLASS.

Nowadays there is no glass so much sought after as Swiss panes. Unfortunately, there is only so much of this to go round, and practically all the best pieces have long ago passed into public or private collections, so that if a piece does come into the market it is instantly snapped up at a high price. This has led to a large number of forgeries of Continental origin appearing in antique dealers' shops and in auction rooms, the manufacture of these amounting to almost a small industry. The skill, however misapplied, with which these are executed is amazing, and the knowledge and study of old work which has gone to the making of them is surprising. Some have even found their way into national collections, so that it is hopeless for the amateur to try to detect the good from the bad, as this will often tax the wits of the greatest experts. One of the most skilful of these forgers is at Düsseldorf. Such men are the cream of a shady profession, and like the swell cracksmen, are after big things and high prices for their work. No amount of pains or trouble must be spared, and they must moreover possess an extraordinary degree of skill in technique and craftsmanship. Naturally enough, a man who was particularly good at imitating Swiss work would be hopelessly at sea with that of the 14th century, but by confining themselves to the glass of one period, forgers become extremely clever at imitating it.

It is, therefore, very difficult to lay down any hard and fast rules, and the safest guide is judgment founded on the continual inspection and handling of Swiss glass. Unfortunately, the opportunities for doing this are not very frequent, but I have been particularly fortunate in this respect, as at an early age I was brought into close contact with one of the largest private collections of Swiss glass in the world, consisting of between four and five hundred pieces, which my father was engaged upon in arranging, classifying and re-leading for many years. Whilst it is impossible to treat the fascinating subject of Swiss technique and craftsmanship within the limits of a paper such as this, the following points should be noted :—

The glass should be extremely thin—as thin as that of the specially thin glass upon which the gelatine film of plates intended to be used in the sheaths of hand cameras is coated. Though it is always dangerous to dogmatize in these matters it may, as a general rule, be laid down that the enamel must be absolutely black when seen by reflected light, not brown or purplish, it must also be quite dull on the surface. An enamel which has fired up to a bright glossy surface as most of the modern foreign enamels do, should be at once rejected. The coloured enamels are all applied thinly, excepting the blue. This has been floated on thickly, probably with a spoon and in a very liquid condition, so that it is frequently "staddled," the enamel tending to collect into spots round some particle of enamel larger than the others. When required in small patches it has been applied to a larger surface than that of the robe or what not which it was required to tint, and the superfluous enamel cleared away with a stick, leaving the edge of the coat of enamel standing up with a sharp clear edge as thick as a couple of visiting cards. The blue generally fired with an eggshell gloss, neither perfectly dull nor very bright and shiny.

In Swiss panes the quill work or strokes where the enamel has been removed to form high lights in grass, diaper patterns, etc., is wonderful. Although in many German reproductions this is very well done, it requires extraordinary dexterity of hand and the forgery is very frequently far inferior to ancient work. In some cases it is very badly done. If we compare the treatment of the grass in this subject of "Wildfowling" with the treatment of the foreground in this forged circle the difference between the two will be at once seen. In the trees one sometimes sees examples where touches of paint have been applied to the glass to show separate leaves or tufts of leaves, as in water colour painting on paper. But old work was not done that way. A few traced lines were first applied in the manner of the wood cuts of that period, a wash of enamel was applied to represent the darkest parts and then a flat wash over all, the enamel which had overspread the tree and covered the sky being cleared away, and leaving the tree flat. A few lights were afterwards removed to give the light portions of tufts, etc.

In the architecture at the sides of the panels the lines on the edge of mouldings etc., are in the best old work absolutely straight and parallel and at perfect right angles to each other. This shows that the glass was fixed up on an easel formed of a sheet of glass in a perfectly rectangular wooden frame upon the edge of which a T square could be used as in a drawing board. The glass was waxed up in the usual manner and the lines where scratched out with the pointed end of the stick or the quill pen were, therefore, perfectly straight and square. Indeed, Jost Amman, who as one of the most prolific designers for Swiss glass who ever lived, was, therefore, in a position to know, shows such an arrangement in his wood-cut of a glass-painter at work. Genuine examples where the lines are not perfectly straight and regular, but which have been done free-hand, can be found. They are, no doubt, the work of learners or inferior artists, but, on the other hand, such work is more frequently an indication of the work of an imitator.

In imitations one also frequently sees the technique of the painting of the drapery differs from that to be seen in the best old examples. The operator was fully aware that instead of removing the colour to form the lights with short brushes, the old artists employed nothing but a stick or a quill, but the way in which these implements have been used is incorrect. Long, straight strokes have been scratched out along the length of the folds of drapery, but that was not the method of handling usually employed. If we examine a piece of actual old work closely we see that the lights were taken out in a mass of curly, scribbly lines, which as the lights recede into the shadows give place to a series of dots gradually diminishing in size.

The treatment of the diaper patterns on the backgrounds in Swiss work is very characteristic and they should be carefully examined. Very frequently a stencil * has been employed.

---

* Stencils are mentioned in a MS. on glass-painting of the XVIth century, printed by L'Abbé Texier, in his Histoire de la Peinture sur Verre en Limousin, 1847, p. 107, as follows :—" Et, pour égayer davantage. . . . avec un cuivre ajusté pour afréger, tu traceras dans la conduite des creux (du cuivre) ornements et rinceaux comme jaillissant de vases, et se reliant ou bien formant couronne et bouquets enlacés." The Abbé Texier remarks :—" A la vue des mêmes ornements répétés sur des verres de couleurs différentes, nous avions soupconné que le trait si coulant et si pur des ornements de cette époque peints sur les vitraux était dû trop souvent à un procédé mécanique. La publication de ce fragment ne peut laisser de doute à cet égard "

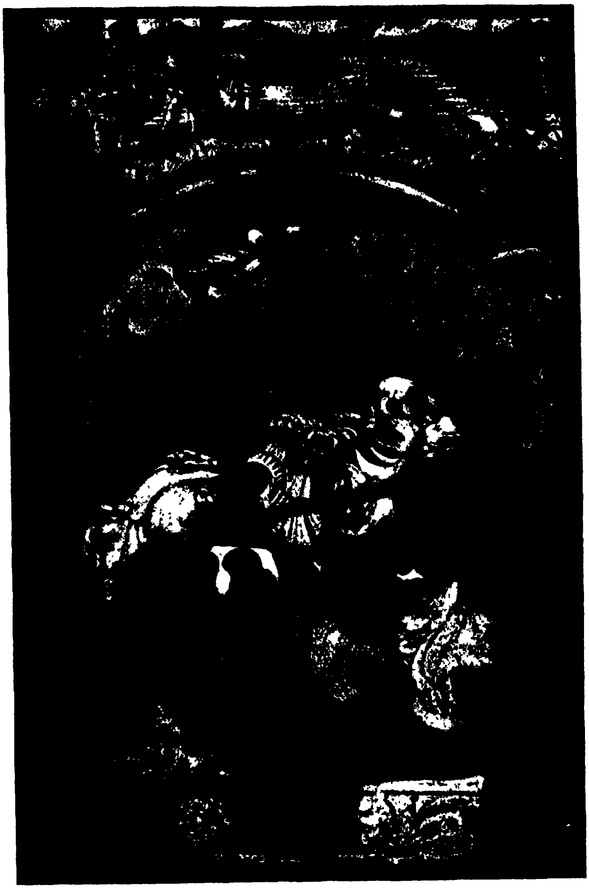

FIG. 7.—Swiss Glass.
Diaper Background Stencilled.

As is always the case with such makeshifts, the pattern when done mechanically never fits and is always too large or too small for its place, and how the old artists could tolerate such rubbish surrounded as it was with work done with the most infinite zest and the most excellent fancy, I can never understand. But there it is, and the fact has to be accepted. Yet though the forger may be perfectly aware that stencils were formerly employed, and he therefore employs one also, he is not always careful to use it in the old way. For nowadays in stencilling on glass—which I blush to admit is still done, especially in the United States and by men who claim to be "art craftsmen"—the glass is first painted with a flat coat of enamel and the stencil laid over it. The paint seen through the holes is then removed with a tooth brush passed quickly over it. By this method the result is never sharp and clean, especially where an old stencil has been used which has become twisted and bent and does not lie flat on the glass. But old work was not done that way, as a close examination shows. The stencil was evidently laid on the glass as before, and a pointed stick or quill passed round each hole in exactly the same way as a glazier cleans away the superfluous cement which collects up against the leads when cementing a light. The ground of the pattern was then cleaned out by hand with a brush. By this method the amount of time saved, if any, would be very slight and the result not worth the small amount of pains taken.

One word in conclusion. It is a great mistake to get into the habit of suspecting everything one sees, like a child who imagines there is a bear lurking in every dark corner on the way to bed, and this is an attitude of mind to which "experts" are very prone, so that eventually they come to suspect their own shadows. A little common sense is often a more reliable and trustworthy guide than an opinion which has to be paid for. It is obvious that a man will not go to ten times the amount of trouble to fake a piece in order that it may pass as old, when he could do a new one in half the time, unless he is going to be well paid for his trouble, so that pieces which are offered at a reasonable figure are generally either perfectly genuine or of the class of obvious shams which are turned out by scores and by hundreds. For example, I have pieces of 13th century grisaille, and circles of 16th and 17th century workmanship which cost less than £2 each and were exposed for sale in shops in Paris, where anyone who was lucky enough could have picked them up. On the other hand, I have seen stocks of similar circles and squares in antique shops in Cologne the products of factories which make a business of it, offered for a few shillings each. In neither case was it necessary to exercise expert knowledge to know that the one was as obviously genuine as the other was transparently the reverse.

DISCUSSION.

The Chairman (Mr. Bernard Rackham), in opening the discussion, said the subject of Mr. Knowles's paper was of the very greatest importance to all those who loved old stained glass, and more particularly to those—and there was an increasing number of them—who collected stained glass, whether on their own account, or as trustees of National collections. There were several points which Mr. Knowles had mentioned which had suggested themselves to him as being of special interest, particularly that of the uneven action of corrosion; an example of which had been shown on a slide representing the Virgin and the figure of Christ. There was at South Kensington a very charming little panel of the Virgin sitting on a bench in the open air which, in the past, had puzzled him very much. The explanation of his puzzlement had been afforded him some time ago by the late Maurice Drake. He desired to take the opportunity of saying that Maurice Drake's death had been a very serious loss to all those who were interested in stained glass. Nobody had a more sympathetic understanding of the art, and a greater love for it than Maurice Drake. Maurice Drake had pointed out to him that it was quite possible that the panel in question might have been unevenly subjected to the action of moisture. The upper part of the panel was perfectly clear; the glass was beautifully smooth, and there was not a trace of decay or corrosion in it at all. The lower part, on the other hand, was badly pitted with corrosion. It was a very strange thing to see, but it could be explained, he thought, by the fact that, by some accident, the lower part had been exposed to the weather, and the upper part had been protected from it.

With regard to the question of glass, he had been shown the other day a representation of some small heads brought from a small village in Normandy, which purported to be of the Thirteenth Century. They were of the Thirteenth Century, but not wholly so. The glass was undoubtedly the ordinary pinkish glass of thick composition which was universally used in the early Thirteenth Century to represent the flesh portions of the figure, but the features painted on the glass were certainly not original. The point was that there was in existence glass which was completely forged glass, but there was a much more dangerous class of forgery, namely, that of which half was composed of the original material but in which the painting and the pattern were not so composed.

There was another point which deserved consideration. It was obvious that stained glass windows must have been subject, if not to forgery, at least to modification. Ever since the day when it had first been made, a Thirteenth Century window was bound, in the course of time, to get broken by some accident or another. A hole occurred in it, and it had to be filled with glass of the period at the time the accident occurred. There must be many stained glass windows, additions to which had had to be made. They were not forgeries, but modifications and additions, which might have happened at any time subsequent to the original erection of the window. That would account for some very puzzling phenomena which were occasionally seen. For instance, Mr. Knowles had shown him some time ago an instance of that in the celebrated East window at St. Margaret's Church, Westminster, which was a very fine interesting piece of work of the Sixteenth Century, but which had been modified at a later date—in all probability at the time when the window had been erected at Westminster. That window showed a great quantity of dusky enamel, which was quite foreign to the style of the period when the original window had been made.

He might mention that at the Victoria and Albert Museum they had not only the glass which was exhibited to the public, but also a collection of small pieces of glass which were too small to be exhibited, but which would be of the greatest interest to all students who desired to come to close quarters with the subject of glass technique. He was glad to have the opportunity of making that announcement because, after all, it was the desire of those in authority at South Kensington, that the collections there should be made as useful as possible. Therefore, if those who loved, and made a study of, stained glass desired to take the advantage of seeing those small specimens at the Museum, they would be heartily welcomed there.

Mr. Noël Heaton expressed his appreciation of the paper and congratulated Mr. Knowles on breaking new ground in explaining the difference between genuine and forged stained glass. It must have been an extremely difficult task to collect all the evidence which Mr. Knowles had produced that night. The author had begun by explaining the difference between a reproduction of old glass and a forgery of old glass. It seemed to him (the speaker) that the line between the two was a very finely drawn one, and he was afraid, in some cases, one might merge into the other. He had not the slightest doubt that in some cases old glass might have been copied for quite honest and genuine purposes but that it had subsequently got into the hands of other people, who, either in ignorance or otherwise, had passed it on as the genuine thing, and therefore what had been orginally an honest reproduction, had passed into the category of a forgery.

There were some who went as far as to say that any sort of reproduction of old work was to be deplored—that when a man restored ancient stained glass which had been damaged, he should not in any case reproduce the original design but leave blank any bits that had been broken out, or at most mat them over so that there should be no mistaking the old and new work. Personally he confessed that he could not altogether approve that idea. He thought reproduction, as long as it was clearly understood that it was reproduction, was all to the good. When reproductions were very well done, in some cases one could easily be deceived by them. He frankly confessed that he had been deceived in that way quite recently by the East window at Auxerre Cathedral. He had begun admiring it as a magnificent example of Thirteenth Century work until, on closer inspection, he began to see the details of the design, and finally he discovered from the guide book that the window had been blown out by a shell in the Franco-German war, so that it could not have been original Thirteenth Century glass.

There were one or two points of detail on which he did not altogether agree with Mr. Knowles—for instance, on the point of thickness of ancient glass. Mr. Knowles had said that mediæval glass was always thinner than modern glass. That held good to any time back to the Fourteenth Century, but surely it did not apply to the very earliest glass, particularly to the early Thirteenth Century. Surely one got there a glass which was characteristically thick, and of uneven thickness, and always in small pieces? He did not think a piece of early Thirteenth Century glass would ever be found which was more than four or five inches long and two or three inches wide. He ascribed that to just the reverse reason to that which Mr. Knowles gave—and which was perfectly correct in regard to later glass. In those early days people could not make the glass thin, because it was more difficult to get it thin than it was to make it thick. In order for glass to be made into thin sheets it had to be pretty fluid and easily blown. In those early days the furnaces were very imperfect; the glass could not be brought easily to a state of great fluidity. Also it was a glass which was of a very stodgy nature. They could not gather very much on the rod; consequently, they got very small and very thick pieces. Later on, as their technical skill grew, they obtained the characteristic thin glass to which Mr. Knowles had referred.

The author had also said very definitely that one never found "foxiness" in the enamel of old glass. He admitted it was very uncommon to do so, but he had seen several examples of certainly genuine stained glass of about the latter half of the Sixteenth Century where that "foxy" colour of the enamel had been quite distinct. He would like to emphasise what had been said as to the enamel or "colour" used in mediæval times never being fired to a glossy surface. This was perfectly true and it was rather an important point from the technical point of view. There was a belief amongst modern glass painters that the enamel could not be permanent unless it was fired to a varnish surface. As a matter of fact, the more fusible and less durable the enamel was the more readily it gave this high gloss. In mediæval times they used an enamel actually harder than the glass and so loaded it with pigment that it fired dead and that was why they could obtain that strength in the fine lines which Mr. Knowles had demonstrated. If one were to offer an enamel of that type to a modern glass painter, he would not use it.

Mr. Knowles had described various ways in which corrosion could be imitated, and had pointed out that those imitations could very easily be detected. He had further said that actually to reproduce genuine corrosion was a thing that could not be done. That was generally admitted to be the case —so much so that it was very often considered the most reliable test of genuineness; he (the speaker) considered that it was quite practicable to produce genuine corrosion by artificial means. This was a very different thing from trying to imitate the effect of corrosion in the various ways described in the paper. Some years ago he had been investigating the causes of the peculiar pitting which took place in glass. There had been a controversy for a long time between those who said this was purely a question of the composition of the glass and those who said that it was due to the action of the growth of certain minute forms of vegetation on the surface of the glass. He claimed that it was entirely a chemical and physical matter. If this theory were correct it should be possible to produce the corrosion artificially if one had sufficient scientific training to carry out the necessary operations. To prove his theory he had set to work, and had actually corroded glass artificially. It was not altogether easy, but it was not a matter of extreme difficulty if one knew the way. He had never published or said anything about the matter up to the present moment, because if it became generally known how glass could be artificially corroded, a very potent weapon would be put into the hands of the forgers. By ageing the glass in the particular way which he had discovered, he would back himself to produce specimens of "'ancient stained glass" which would deceive Mr. Knowles himself.

Finally, on the question of the uneven resistance of glass to corrosion, he endorsed the remarks made by Mr. Knowles. He ascribed the variation of durability to a combination of two or three circumstances. One was the unequal exposure to the weather; another was the difference in the composition of the glass; it was quite easy to see how one could get differences of composition even in the same window; and the third was the way in which the glass had been fired. The firing of glass in mediæval times was very crude and irregular. If one put those three circumstances together, one could easily understand that the resistance to corrosion in glass would vary very considerably. The same thing happened even at the present time. He knew of one case where, even in recent years, in a window which was otherwise perfectly sound, one or two pieces had absolutely gone to ruin already. That was because a particular kind of glass had been used which had been badly made. If that sort of thing could happen in the present day, when technical knowledge in the trade was so great, one could well imagine that the composition in mediæval times might vary to such an extent as to account for the extreme differences which were found.

Dr. T. M. Legge, C.B.E., said the only point at which he found himself at variance with Mr. Knowles was when he said that corrosion always appeared black against the glass. Personally he knew a window of St. Margaret spearing a dragon of Fifteenth Century workmanship, in which the dragon's wings were blue with yellow stain so as to make it greenish, and the ribs in the wings and the spots were all originally in black enamel. Those had been the lines and the particular points on which corrosion occurred. They had all disappeared, so that now there were white lines against the green where formerly there had been black.

Mr. F. S. Eden said there was one point on which he would like to make a few remarks, namely, upon the difference between forgeries and honest reproductions. He had had considerable experience of both, and it had occurred to him that it would be a very good thing indeed if some system could be devised which could be, he would not say universally but at least in this country, adopted for reproductions. So long as there were expert men doing the work in exactly the same way as the workers of the Middle ages did it, so long would there be the danger of so exact a reproduction that it might, in the eyes of the many, amount to a forgery. As Mr. Noël Heaton had pointed out, even if it had been originally an honest reproduction, in the course of time the reproducer died, his executors came into possession of the glass, sold it by auction, and, perfectly honestly, sold it as ancient glass. So long as that sort of thing went on it would depend entirely upon the ability of the original painter as to whether it should be ultimately accepted as an honest reproduction or as a forgery. He suggested that reproductions should be made by some vehicle which could be easily detected by the expert, but which, nevertheless, gave a fairly good representation of the work which it was supposed to represent. All glass painters, and most literary men who dabbled in the subject, knew that in the Fourteenth Century artists painted in varnish colours on white glass, in somewhat the same way as, since the Sixteenth Century, glass painters had painted with colour enamels, but that varnish painted glass was not fired. It gave, at first sight, when put in the window, a fairly good representation of the subject it was supposed to represent, but if an expert looked at it he knew what it was at once. There was no possible question of deceit, and at no time could it ever be put up for sale as a piece of genuine work. If only that plan could be adopted at the present time, it would solve the whole question of forgeries. Nobody, he supposed, had seen more of genuine glass and forged glass than himself, and he quite admitted that he had been over and over again deceived. On many occasions he had at first sight thought that reproductions had been ancient work, simply owing to the extreme ability of the modern painter. If there was some medium of translating old glass to modern folk in a form that could not be mistaken by experts for ancient work there would be no more trouble.

Mr. Walter Tower remarked that no mention had been made in the paper about the date of forgeries. He enquired whether Mr. Knowles could state what was the earliest known forgery. He imagined himself that most forgeries began about one hundred years ago, but if there were known forgeries earlier than that, it would be interesting to hear of them.

One point which had struck him was that in connection with corrosion, Mr. Knowles had stated that the pit holes nearly always stopped when they came next to stain; that was to say, the stain acted as a kind of protection against the corrosion. One had often seen cases where the pit holes seemed to skirt the edge of the stain in a very decided way, but, on the other hand, one had seen exactly the contrary of that, where the pit holes had gone across the stain. That was rather an interesting point, the explanation of which might be that given by Mr. Heaton, who had said that it had to do either with the manufacture and quality of the original glass, or the nature of the firing: that being the reason why corrosion had stronger effects on some pieces of glass than it had on others. Whether that was the reason why pit holes stopped against stain he was not personally prepared to say, but he would like to have the author's opinion on the point.

Mr. F. C. Eeles gave instances of certain forgeries which he had come across, and said that he felt it was really essential that there should be some way by which, on close examination, one could detect what was old work and what was new. in cases where anything of the nature of reproduction was held to be desirable. With regard to the thickness of old glass, he knew of cases of undoubted Fifteenth Century glass where, in the same window, the glass in some parts was very thick indeed, and in other parts was of extreme thinness. The instance of the Sherborne glass mentioned in "The Times" that day, showed that there could be a very great variation in the thickness of the glass in the same window of the same date. Again, in some Kentish glass which he had been handling recently, the glass in the tracery of Fifteenth Century windows was really very thick—as thick as Thirteenth Century glass—whereas, in the same window for the glass in the main lights, the glass-makers of the period seemed to have selected about the thinnest glass they could find.

Mr. Knowles, in reply, said in regard to those cases where the glass was old and the painting new, that was an instance where half a truth was ever the blackest of lies; and unfortunately, such things were very frequently done.

With regard to Mr. Noël Heaton's point about thickness, he had not the slightest doubt that Mr. Heaton was right. He would also not attempt to argue with Mr. Heaton on the other points he had raised, because Mr. Heaton had made himself an expert on the subject of corrosion.

He did not know when the earliest forging took place, but it could not have been very long ago. When the collections of Swiss glass were brought to England, one could have had the glass for the asking. Nobody thought anything of it. It was only quite recently that old glass had been thought much of. Horace Walpole told how he sent an Italian to the Continent who fetched back 450 pieces, for which, and for the expenses of the journey he paid only thirty-six guineas. Therefore, forgery must be quite a modern thing.

With regard to the difference between a forgery and a reproduction, he could see no good at all in making a copy of anything excepting for educational purposes for the Museums, and so forth; but there must be the very greatest temptation for a man who became clever in making such things to make small pieces which could easily be sold and deceive people. It perhaps might be a good thing if the British Society of Master Glass Painters devised some rules with which everyone of their members who made a copy had to comply, in order to prevent any mistake.

With regard to stain protecting the glass from corrosion, the yellow stain very frequently did that. He did not say that corrosion was never seen where the stain had been applied, but he did say it was very rare to see it.

Mr. A. A. Upjohn (Master of the Glaziers' Company), in moving a hearty vote of thanks to Mr. Knowles for his paper, said all those present were lovers of paintings on glass, and as such it had been of great interest to them to listen to the paper which had been read by Mr. Knowles, who was the great master glass painter of York. Mr. Knowles was not only well known in York, but throughout the whole of the kingdom, as an authority on the subject. It was clear that Mr Knowles had been reared on glass, and that the great city of York which contained so much old painting on glass had been a great field for him. He was sure those present were greatly indebted to Mr. Knowles for the amount of time and thought he must have given in the preparation of the paper, and he would ask them to give him a very hearty vote of thanks.

The vote of thanks was then put and carried unanimously, and the meeting terminated.

Mr. G. Wüthrich, M.I.E.E., writes: When I am on the eve of a new panel acquisition, I naturally ensure that the "leading" is of the right mould, and that the dust of lead oxidation is not overdone—that is, of course, if the lead is supposed to be contemporary. The glass must be of the correct texture, tint and thickness, and, above all, of the epoch corresponding with the heraldic and architectural design, and the production and application of the enamels and stains used; the grinding off of "flashing" must be "hard" and not "soapy," "washy" and acid borne; the corrosion pits must be of the right shape and correctly edged, not "tooled" or "acid etched." The cracks in repaired panels, if made good, must be "bridged" and not "filled," otherwise the panel must be deformed and wider by the total thickness of all the lead fissures inserted. The caligraphy of the dates, must be strictly of the correct period, and there must be no "halo" coming from the grinding out of figures, especially the century numeral in, say, 1682, which the forger very much likes to change into a 5, making it 1582; thus pre-supposing that the discrepancy between the heraldic or ornamental features and the new "old period" will escape the eye of the innocent collector.

The perusal of Mr. Knowles' paper demonstrates that there are a hundred and one things which must be observed to ensure protection against the craftmanship of the forger. He is only too right in stating that the modern forger does not frequently operate so clumsily; the forger is an expert craftsman incarnate, and I am afraid that the only real protection against his handiwork lies in that flair, instinct and touch which comes from the sad contemplation of many and costly errors. Much more reliable than the application of text books and rule of thumb methods is the advice of an expert such as Mr. Knowles, or, in Swiss stained panels, of Dr. H. Lehmann, Director of the Swiss National Museum of Zürich. Then one can enjoy the consciousness of possessing "the real goods," and need not suffer under the stealthy uneasiness that is inseparable from half-knowledge.

The modern forger should be fought tooth and nail. Collectors should sink their bashfulness and assist potential buyers and art experts in ruthlessly bringing the malefactors to book. Art Societies should organise and combine in stamping out this pest.

CORRESPONDENCE.

EXHIBITIONS.

In his fascinationg address on "Exhibitions," Lord Askwith enumerated several of the "material results" we owe to the Great Exhibition of 1851.

There was, however, one that he did not mention which might be commended to the careful consideration of the authorities of the British Empire Exhibition of 1924, as worthy of imitation. I refer to the Science Research Scholarships (including the later Industrial Bursaries) which are provided out of funds derived from the 1851 Exhibition. That scheme affords opportunities for research to students from all parts of the Empire and the list includes several who have made notable additions to knowledge in recent times. Many have subsequently been engaged in industry and thus the scheme has aroused public opinion to an appreciation of the value of applying science to industry.

This aspect of the subject is peculiarly appropriate to the moment, when a drastic change in fiscal policy is suggested as a solution of the problem of unemployment, to a country whose industrial history is full of examples of new fields of productiveness and employment which have been opened up by the application of the results of pure scientific investigation.

WALTER C. HANCOCK.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evening, at 8 o'clock:—

DECEMBER 12.—SIR FRANK BAINES, C.B.E., M.V.O., Director of Works, H.M. Office of Works, "The Preservation of Historic Buildings and Ancient Monuments." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., will preside.

INDIAN SECTION.

Friday afternoon, at 4.30 o'clock.

DECEMBER 7.—WILLIAM FOSTER, C.I.E., Historiographer, India Office, "The Archives of the Honourable East India Company." (Sir George Birdwood Memorial Lecture.) THE Rt. HON. VISCOUNT PEEL, G.B.E., Secretary of State for India, will preside.

DOMINIONS AND COLONIES SECTION.

Monday afternoon, at 4.30 o'clock.

DECEMBER 17.—WM. C. NOXON, Agent-General for Ontario, "Empire Settlement." The EARL OF AIRLIE, M.C., will preside.

PAPERS TO BE READ AFTER CHRISTMAS.

G. ALBERT SMITH, "Cinematography in Natural Colours—further developments" (with illustrations—scenes from H.R.H. The Prince of Wales's Tour in India).

IYEMASA TOKUGAWA, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

SIR RICHARD ARTHUR SURTEES PAGET, Bt., "Fused Silica and its use as a Refractory Material."

H. MAXWELL-LEFROY, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., will preside.

PERCIVAL JAMES BURGESS, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

CHARLES S. MYERS, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MRS. ARTHUR MCGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

ALAN A. CAMPBELL SWINTON, F.R.S., late Chairman of the Council, "Recollections of some Notable Scientific Men." (Illustrated by Photographs.)

Sir Richard M. Dane, K.C.I.E., Commissioner North India, Salt Revenue, 1898-1907; Foreign Chief Inspector, Salt Revenue, China, 1913-18, "Salt Manufacture in India and China."

Brigadier-General Henry Alfred Young, C.I.E., C.B.E., late R.A., Director of Ordnance Factories, India, 1917-21, "The Indian Ordnance Factories and Indian Industries."

Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Colonel H. L. Crosthwait, C.I.E., R.E., retd., late Superintendent, Survey of India, "The Survey of India." Sir Thomas H. Holland, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, will preside.

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

F. W. Walker, "The Commercial Future of the Backward Races, with Special Reference to Papua." **Sir George R. Le Hunte**, G.C.M.G., will preside.

The Hon. T. G. Cochrane, D.S.O., "Empire Oil: The Progress of Sarawak."

INDIAN SECTION.

Friday afternoons, at 4.30 o'clock.

January 4, 18, February 15, March 21, May 2.

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons, at 4.30 o'clock.

February 5, March 4, April 1, May 27.

CANTOR LECTURES.

Monday evenings, at 8 o'clock.

Aldred F. Barker, M.Sc., Professor of Textile Industries, The University, Leeds, "Recent Progress in the Wool Industries." Two Lectures. December 3, 10.

SYLLABUS.

Lecture II.—December 10th. Processes:—Brief review of developments of the past hundred years. Basic principles revealed by this review. Recent improvements in the principles of manipulation of the raw materials. Recent mechanical developments. Prospective manipulative and mechanical developments. Distribution of the Industry:—The present distribution and the principles of distribution involved. Prospective distribution.

Eric Keightley Rideal, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." Three Lectures. January 21, 28; February 4.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

COBB LECTURES.

Monday evenings, at 8 o'clock.

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures March 24, 31; April 7.

DR. MANN JUVENILE LECTURES.

(*Special tickets are required for these Lectures*).

Wednesday afternoons, at 3 o'clock.

Dr. William Arthur Bone, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology. "Fire and Explosions." Two Lectures. January 2, 9. The Lectures will be fully illustrated with experiments.

Mrs. Julia W. Henshaw, F.R.G.S., Croix de Guerre, "Among the Selkirk Mountains of Canada (with ice-axe and camera)." One Lecture. January 16. The Lecture will be fully illustrated with hand-painted lantern slides.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, December 10..Geographical Society, Lowther Lodge, Kensington Gate, S.W., 5 p.m. Dr. A. T. Doodson, "The Work of the Liverpool Tidal Institute."

Swiney Lecture, King's College, Strand, W.C., 5.30 p.m. Dr. W. T. Gordon, "Gem Minerals and Their Uses in Art and Industry." (Lecture X.)

Surveyors' Institution, 12, Great George Street, S.W., 8 p.m.

Farmers' Club, at the Royal United Service Institution, Whitehall, S.W., 6 p.m. Annual Meeting. Mr. A. Mansell, "The Influence of Pedigree on the Ordinary Farming Stock of the Country."

Metals, Institute of (Scottish Section), 39, Elmbank Crescent, Glasgow, 7.30 p.m. Mr. A. T. Adam, "Cold Working of Metals and its Influence on the Properties and Uses."

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Mr. W. Dale, "Egypt in the days of Akhenaten and Tutankhamen."

TUESDAY, DECEMBER 11..Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. L. R. McCollum, "Modern Rotary Drilling Systems."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 8 p.m. Messrs. G. Herbert and R. A. Ives, "Some Applications of Illuminating Engineering in Practice."

University of London, University College, Gower Street, W.C., 5.30 p.m. Baron A. F. Meyendoitt, "Legislative Procedure in Russia before 1905."

5.30 p.m. Miss H. D. Oakeley, "The Roots of Early Greek Philosophy." (Lecture III.) 5.30 p.m. Professor H. C. H. Carpenter, "Metallic Crystals and Their Properties." (Lecture II.)

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Sir William Vincent, "British Rule in India—What it has achieved."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Discussion on Mr. Blocksidge's paper, "Life Saving Appliances on Cargo Passenger Steamers."

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. "The Dusun of British North Borneo."

Metals, Institute of (Birmingham Section), Chamber of Commerce, New Street, Birmingham, 7 p.m. Major R. M. Sheppard, "Extension Problems."

(N.E. Coast Section), Armstrong College, Newcastle-on-Tyne, 7.30 p.m. Messrs. S. G. Homfray and J. Adam, "Admiralty Gun Metal."

Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment. W.C. (Graduate Section). Mr. C. Anderson. "Ministry of Transport Requirements with Reference to Railway Companies."

Master Glass Painters, British Society of, in the Lecture Theatre, Victoria and Albert Museum, South Kensington, S.W., 3.30 p.m. Dr. M. R. James, "The Eton Wall Paintings: Their Relation to Stained Glass and other forms of Art."

WEDNESDAY, DECEMBER 12..African Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi. W.C., 5 p.m. Mr. C. F. Rea, "The Arussi and other Galla of Abyssinia."

University of London, Westfield College, Hampstead, N.W., 5.15 p.m. Professor Craigie, "The Making of a Dictionary."

United Service Institution, Whitehall, S.W., 3 p.m. Wing Commander C. H. K. Edmonds, "Air Strategy."

British Decorators, Institute of, Huddersfield. 7.30 p.m. Mr. W. H. Cantrill, "A Pilgrimage to the Hill Towns of Umbria."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. B. H. Morgan, "The Work of the Imperial Economic Conference."

Civil Engineers, Institution of, Great George Street, S.W., 7 p.m. (Informal Meeting.) Messrs. W. P. F. Fanghaenel and W. N. Booth, "The Lighting of Factories."

Mechanical Engineers, Institution of, Cardiff. 7.30 p.m. Mr. H. D. Madden, "Mechanical Engineering in Modern Gas Works."

Swiney Lecture, King's College, Strand, W.C., 5.30 p.m. Dr. W. T. Gordon, "Gem Minerals and Their Uses in Art and Industry." (Lecture XI.)

Transport, Institute of (N. Western Section). The University, Liverpool. Mr. R. D. Holt, "Ocean Transport."

Textile Institute, St. Mary's Parsonage. Manchester. Mr. E. C. Barton, "Decimal Progress."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., 6.30 p.m. Mr. H. D. Nickinson, "Some Experiments in the Lubrication of Commercial Vehicle Engines."

THURSDAY, DECEMBER 13..Engineering Inspection, Institution of, at the ROYAL SOCIETY OF ARTS, John Street. Adelphi, W.C., 8 p.m. Mr. W. Allsup, "Gauging, Gauge Design and Inspection."

University of London, at the London School of Economics, Houghton Street, Aldwych, W.C., 5.30 p.m. Mr. H. H. Gordon, "The Financial and Municipal Problem of London Traffic."

6 p.m. Mr. J. Lee, "Public Administration from Within—The Psychology of Communication."

At the Royal College of Surgeons, Lincoln's Inn Fields, W.C., 4 p.m. Mr. F. W. Twort, "The Influence of Environment on the Life of Bacteria."

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Linnean Society, Burlington House, Piccadilly, W., 5 p.m.

British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. J. H. Sexton, "Fresco Painting."

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Miss Kate Stevens, "My Trip Round the World."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. Mr. D. Brownlie, "Pulverized Fuel and Efficient Steam Generation."

Metals, Institute of, at the Institute of Marine Engineers, 85, The Minories, E., 8 p.m. Mr. A. H. Mundey, "Some Foundry Problems" (Joint Meeting with the Institution of British Foundrymen.)

Literature, Society of, 2, Bloomsbury Square, W.C., 5.15 p.m.

Historical Society, 22, Russell Square, W.C., 5 p.m. Miss R. Graham, "The English Province of the Order of Cluny in the 15th Century."

Central Asian Society, at the Royal United Service Institution, Whitehall, 5 p.m. Capt. F. K. Ward, "Eastern Tibet and Yunnan."

Tropical Medicine and Hygiene, Royal Society of, Endsleigh Gardens, N.W., 8.15 p.m Laboratory Meeting.

Constructive Birth Control and Racial Progress, Society for, at Essex Hall, Strand, W.C., 8 p.m. Prof. E. W. McBride, "The Inheritance of Mental Defects."

FRIDAY, DECEMBER 14..London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Mr. A. T. Edwards, "Good and Bad Manners in London Architecture."

Aeronautical Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.30 p.m. Mr. W. Loth (of Paris), "Leader Cables for Electrical Steering of Aeroplanes."

Metals, Institute of (Local Section), The University, Sheffield, 7.30 p.m. Mr. J. H. G. Monypenny, "The Metallurgical Microscope—some notes on its Construction and Use." At the University College, Singleton Park, Swansea, 7.15 p.m. Mr. A. L. Norbury, Some Applications of the Brinell Hardness Test."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Professor A. H. Gibson and Mr. H. W. Baker, "Exhaust Valve and Cylinder Head Temperatures in High Speed Petrol Engines."

University of London, University College, Gower Street, W.C., 5.30 p.m. Professor A. B. Charlton, "The Dark Comedies of Shakespeare."

Astronomical Society, Burlington House, Piccadilly, W., 5 p.m.

Medical Officers of Health, Society of, 1, Upper Montague Street, W.C., 5 p.m. Dr. H. Scurfield, "On Lines of Advance in Maternity and Child Welfare Work."

Sanitary Institute, 90, Buckingham Palace Road, S.W., 3 p.m. Conference on "Tuberculosis in Cattle and the desirability of Allowing the Introduction of Breeding Heifers from Canada of Certified free from Tuberculosis."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Swiney Lecture, King's College, Strand, W.C., 5.30 p.m. Dr. W. T. Gordon, "Gem Minerals and Their Uses in Art and Industry." (Lecture XII.)

SATURDAY, DECEMBER 15..London County Council, at the Horniman Museum, London Road, Forest Hill, S.E., 3.30 p.m.

Journal of the Royal Society of Arts.

No. 3,708 VOL. LXXII.

FRIDAY, DECEMBER 14, 1923.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 17th, at 4.30 p.m. (Dominions and Colonies Section.) WM. C. NOXON, Agent-General for Ontario, "Empire Settlement." THE EARL OF AIRLIE, M.C., will preside.

FIFTH ORDINARY MEETING.

WEDNESDAY, DECEMBER 5th, 1923; PROFESSOR CHARLES ALBERT SEWARD, M.A., F.R.S., Professor of Botany in the University of Cambridge, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Clark, John Murray, LL.D., K.C., Toronto, Ontario, Canada.
Cullen, Jos. F., Salt Lake City, Utah, U.S.A.,
Goode, Clarence S., M.Inst.R.E., Hinckley.
Hibberd, Reginald James, M.Inst.R.E., Haslemere, Surrey.
Keith, Charles, Kansas City, U.S.A.
Ledigard, Edgar M., Salt Lake City, Utah, U.S.A.
Life, Professor Frank M., Tucson, Arizona, U.S.A.
Manekshaw, F. H., London.
Mitra, S. B., London.
Rayakar, B. V., Bombay, India.
Sethna, F. M., Bombay, India.

The following candidates were duly elected Fellows of the Society:—

Auckland, George Frederick, London.
Elwell, C. F., London.
Harding, William, Loughborough.
Hodgkinson, Thomas Walter, Purley, Surrey.
Hoyer, Anton Gotfred, Durban, S. Africa.
Joughin, Walter James, London.
Levine, Professor Victor E., Ph.D., Omaha, U.S.A.
Lloyd, William Henry, Twickenham.
McEwen, Alfred, New York City, U.S.A.
Medlicott, Samuel Thomas, London.
Sleigh, Arthur Crofton, London.
Trusler, William Thomas, Enfield.
Williams, Samuel Powell, Bradford.

A paper on "The work of the Royal Botanic Gardens, Kew," was read by DR. ARTHUR WILLIAM HILL, M.A., Sc.D., F.R.S., Director of the Royal Botanic Gardens, Kew.

The paper and discussion will be published in a subsequent number of the *Journal.*

INDIAN SECTION.

FRIDAY, DECEMBER 7th, 1923; THE RT. HON. VISCOUNT PEEL, G.B.E., Secretary of State for India, in the Chair.

The Sir George Birdwood Memorial Lecture, "The Archives of the Honourable East India Company," was delivered by MR. WILLIAM FOSTER, C.I.E., Historiographer, India Office.

The lecture will be published in a subsequent number of the *Journal.*

CANTOR LECTURE.

MONDAY, DECEMBER 10th, 1923; MR. PERCY J. NEATE, M.I.M.E., late Master of the Clothworkers' Company, in the Chair.

Mr. Aldred F. Barker, M.Sc., Professor of Textile Industries, The University, Leeds, delivered the second and final lecture of his course on "Recent Progress in the Wool Industries."

On the motion of the Chairman a vote of thanks was accorded to Professor Barker for his interesting course.

The lectures will be published subsequently in the *Journal.*

MANN JUVENILE LECTURES.

Under the Mann Trust a short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, 2nd and 9th January, 1924, at 3 p.m., by DR. WILLIAM ARTHUR BONE, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology, on "Fire and Explosions." The lectures will be fully illustrated with experiments.

A lecture will also be given on Wednesday, January 16th, at 3 p.m., by MRS. JULIA W. HENSHAW, F.R.G.S., Croix de Guerre, entitled "Among the Selkirk Mountains of Canada (with ice-axe and camera)." The lecture will be fully illustrated with hand-painted lantern slides.

Special tickets are required for these two sets of lectures. A sufficient number to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply to the Secretary at once stating for which lectures the tickets are required.

REPRINTS OF CANTOR AND HOWARD LECTURES.

The Cantor Lectures on "The Vulcanisation of Rubber," by HENRY P. STEVENS, M.A., Ph.D., F.I.C., and the Howard Lectures on "The Development of the Steam Turbine," by STANLEY S. COOK, B.A., M.I.N.A., M.I.M., have been reprinted from the *Journal* and the pamphlets (price 2*s*. each) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2.

A full list of the lectures, which have been reprinted and are still on sale, can also be obtained on application.

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES SECTION.

TUESDAY, NOVEMBER 27TH, 1923.

LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

The CHAIRMAN expressed his pleasure in presiding for his old friend, Viscount Burnham. The Council had hoped that they might be able to have in the Chair one of the Prime Ministers of those Dominions that were interested in the West Indies; for instance, it would have been very fitting if the Prime Minister of Canada, a Dominion which had had much to do with recent developments in the West Indies, had been in this country and had been able to attend. Letters of regret at not being able to be present at the meeting had been received from individuals so interested in the Dominions and Colonies as the Duke of Devonshire, Lord Emmott, Lord Kylsant, Lord Harewood, Lord Inverforth, Mr. W. Ormsby-Gore, and the Master of Elibank. Lord Kylsant added: "I am particularly glad that Lord Burnham is giving this lecture, as I consider it an enormous advantage that a distinguished Englishman like Lord Burnham should personally have visited the West Indian Islands." He (the Chairman) agreed with Lord Kylsant in that statement, and hoped that the personal visit of Lord Burnham was one which many of those present would be able to imitate.

VISCOUNT BURNHAM expressed his pleasure in speaking under the aegis of Lord Askwith, than whom few men were more fitted to deal with matters concerning the British Empire. He (Lord Burnham) would ask them to believe that in talking about the West Indies he was by no means posing as an authority able to speak with fullness of knowledge about them or their affairs; he well knew how dangerous a little knowledge was; he would therefore ask to be permitted to indulge in such remarks upon the present state of the West Indies as were obvious to the least instructed.

The paper read was:—

THE WEST INDIES.

By VISCOUNT BURNHAM, C.H., LL.D., D.Litt., M.A.

The Imperial Conference has come to its appointed or, as the cynic always has it, its disappointed end, and the Prime Ministers of the Overseas Dominions have nearly all bidden us farewell until it meets again. On the whole, it has marked an advance in the organisation of the Empire, even though public opinion in all the Dominions alike shows a definite set against the ideals of federation, which were so popular a generation ago when I was myself a member of the Executive Committee of the Imperial Federation League, of which that great statesman and leader of men, whom we sorely miss, the Earl of Rosebery, was the President. Excepting him, I believe I am the last surviving member of that Committee. Events mock at human foresight and nothing is certain but the unforeseen. In those days we had just emerged from the "calico period" of British history, from the "bagman's paradise," when the Colonies, as they were then called, were regarded as fledgelings fed only by the parent bird until their feathers were grown and then expected to shift for themselves in the full plumage of Parliamentary institutions, after a friendly farewell, such as we bade to the unfortunate people of Heligoland in the early nineties. Even the West Indies were marked out for the same valedictory process. Goods were to be bought in the cheapest market and possessions were to be sold in the dearest market. Every part of the British Empire had its price for the boon of separation or, as it would have been put then, of emancipa tion from the old country, which was intended to be a free market and clearing house after the model of the Hanse Free Cities in the Middle Ages or the Treaty Ports of China in our own time. The Colonial Office of the Victorian epoch up to its culminating Jubilee, which strangely upset the official mind by its inspiring call to Imperial patriotism, had a nicely adjusted plan of operations for dealing with the British West Indies. The first step was to forge a federal union under a Parliamentary constitution, which was then supposed to be a cure-all for human ills, in which without racial distinction or local differences all good citizens would combine for the common good. The constitutional arrangements of the various islands were to be assimilated or, shall I say, ignored, and the result was to be a union of hearts and minds, such as Mr. Gladstone predicted in John Bull's other island. It was not quite clear how the transformation scene would be staged, because of the ugly memories of racial riots and disorders, the embers of which were yet smouldering. Consequences are unpitying and the terrible incidents of the Slave Trade, such as Mary Gaunt has painted in her last book, were still a tradition if not a memory among the coloured people of the Caribbean. Then there was the unfortunate example of Haiti, where the French theories of liberty, equality and fraternity had somehow missed fire and been supplanted by the primitive and regrettable methods of barbarism and a massacre of the white colonists. Still, nothing damped the humanitarian enthusiasm of the old Colonial Office. "Try liberty" was the watchword or what is called in current political slang "the slogan" of middle class humanitarianism, and the West Indies were believed to be not only ready, but anxious to be liberated from the yoke of a stony-hearted mother country. Unfortunately for these well-intentioned articles of the official creed, the British West Indies did not want the panoply of full Parliamentary constitutionalism, and they were not sufficiently prepared for human brotherhood to dispense altogether with fancy franchises and political preferences. They thought that the mother country still owed a duty and obligation to the old and loyal colonies, which had never failed her for two centuries of chronic warfare and mutual trade relations. With all the multitudinous difficulties of race and colour, these colonies still required the guiding hand and the protecting shield of England and they wanted none other. The words of the Latin motto of the town of Kingston, the capital of Jamaica, "Hos fovet et curat servatque Britannia mater," were taken to embody a ruling principle in the government of the British Empire, and the West Indies wished—and I say with sincerity still wish—that they be enshrined in perpetuity under the Empire coat of arms. The grant of self-government was to have led up to either of two alternatives—a federal republic of the islands *inter se* or annexation to the United States of America, which was regarded as what was called the manifest destiny of an overburdened and bank-balanced nation of shopkeepers. Many things have happened since then, and the irony of fate has turned to folly the wisdom of the wise. Curiously enough, however, the latter alternative has cropped up again in the last two years. For a long time after the Civil War, the United States had renounced that form of spread-eagleism, which aimed at increase of territory within the Union with its disturbing effect on party politics, especially as in the first instance these additions to the South obviously threatened the domination of the Republican Party, which had followed the "carpet-bag" régime in the Southern States. California, Texas, and New Mexico took quite a lot of digesting even after the Civil War. Recently, however, the taste for Imperialism has again taken hold of the American people and has been much stimulated by the opening of the Panama Canal and the necessities of the Prohibition Party. This year Senator Reid, of Missouri, raised the question of the British West Indies in the Senate. He said they threatened the mouths of the Mississippi and the entrance to the Canal and moved that negotiations should be opened for their transfer to the United States in part payment of the War debt of Great Britain. Mr. McAdoo, the son-in-law of President Woodrow Wilson, first started this little game and with his tongue in his cheek averred that such a moral surrender would be to the advantage of both nations. It is only fair to say that the United States Government gave no support to the proposal, but it is supported all the same by a considerable part of the newspaper press, including the *Chicago Tribune*, which is the most important journal of the Middle West. Even more serious is the use being made of the claim by the Prohibitionist Party in the course of their internecine struggle with the "bootlegging" industry, for this may in time make it a plank in the party platforms with all the political mischief that may ensue. The Chief Justice of the Bahamas had reason to speak out about the slanders directed against the colony quite recently. A London daily newspaper had actually acquiesced in the monstrous demand that the Bahamas should be handed over to the United States on the ground that it had become a centre of "American crooks and gunmen." The Chief Justice said: "It cannot be too widely known that in no part of the British Empire is there greater security of life and person and property." From what I saw in my short visit this spring, I can heartily endorse this pronouncement, but the need for making it shows how insidiously the machinery of propaganda is at work. The other reasons for the annexation movement are commercial and financial, and there is no doubt that the peaceful penetration of American trading acting with the passive assistance of British apathy has had a great effect upon the social economy of the West Indies.

In Tom Cringle's Log there is a vivid description of the entrance of the *Firebrand*, one of the ships of King George's Navy, into the port of Santiago de Cuba, in the course of which he speaks of the "sleepy folds" of "the golden flag of Spain," but qualifies it by saying: "The Spaniards in their better days were a kind of coral worm; wherever they planted their colonies they immediately set to covering themselves in with stone and mortar." For a long time past the British Government has not been even a "kind of coral worm" in the West Indies. Even in those days Tom Cringle talked of the "political fermentation" caused by the United States "in those countries," but the fermentation is much more commercial than it is political to-day, and it is only fair to say that but for the business enterprise and organising "lay-out" of the United States the British West Indies might well be on the financial rocks of bankruptcy to-day. The West Indian Colonies have been called "Islands of Samples," on account of the multiplicity of their products and the small scale upon which each has been developed: but America resolved to turn the samples into big business and has, on the whole, been very successful. Sir Charles Lucas prophesied that the twentieth century would witness the regeneration of the West Indies as the nineteenth century had been their time of decadence and decay, mostly, as we all know, on account of the callous and selfish policy prompted by short views and economic fallacies pursued by Great Britain at the behest of the Cobden Club. You will all recollect how sternly the elder Pitt in the majesty of his greatness rebuked the Member of Parliament who laughed when in the course of a great speech he uttered the word "sugar," but laughter such as this has nothing but bitterness in it for those who can laugh at the folly and the perversity of the sugar policy of Great Britain in the last century, which enriched and fortified her enemies and confounded and brought nigh to ruin her own plantations and provinces. The Great War caused unexpected revival in the sugar industry of the West Indies. Mortgages were paid off and sugar mills equipped with modern machinery. Even if prices have fallen and fluctuated since, as was only to be expected, the state of the sugar trade within the British Empire is much better and sounder than it has been for fifty years, and the announcement made by the President of the Board of Trade at the Economic Conference will give it an assurance and stability which it has woefully lacked in the past half century. Under the Reciprocal Trade Agreement of last year, Canada gives Canadian products a preference of 50 per cent. at most with a sliding scale downwards, and it is certain that, as the population of the Dominion grows and her vast territories are brought under settlement, their consumption of West Indian exports will increase proportionately, for Canada has no tropical or sub-tropical lands within her borders. The United States, none the less, is still a good customer, although she has lost some of her import trade into the British West Indies, which, according to the Trade Commissioner's last report, showed a falling off last year of 40 per cent. as compared with 1921 against only 24 per cent. in the case of Great Britain and an actual increase in the case of Canada. Canada, indeed, has not only captured some of the American trade, but has also obtained important contracts for railway extensions and dredging works. What the United States have done is very effectively to promote the production of sugar on a large scale in Cuba, where there are mills turning out 100,000 tons and more in the year, and to give a secure preference in their mighty markets to the output of American interests in tropical industries. I use the word "interests" advisedly because I know that Cuba is a Sovereign State and does not accept, even in theory, any suzerainty in derogation of her independence, but in practice the United States treats Cuba as being almost a puppet within her sphere of influence and exploits her resources with vast momentum. Only this year the United States Treasury advanced forty million dollars in aid of Cuba's financial budget and appointed an Ambassador there, who appears to be more of a Comptroller than a diplomatic representative, and in Cuba American business houses have embarked in huge and productive enterprises on the big scale. Havana itself is being laid out and developed by American capital into a Southern city of splendid surroundings on the finest lines of American town planning. All this points the moral of a comparison between the starvation policy that Great Britain has pursued in her colonies, and the characteristic courage of American business, which is statesmanship marked "pr.vate enterprise." The British West Indies need, so they tell us, a combination of British initiation and British resources to undertake their restoration to the prosperity of other days, but, when a West Indian merchant or planter makes a proposal involving the assistance of British capital, he is met, as I had reason to note the other day, by our banking houses with the reply, "Why try to make a British company when you can get the money so much more easily in New York?" That is partly the explanation why the trade in bananas, which has been the salvation of Jamaica, has passed almost exclusively into the domain of American enterprise. The United Fruit Company is a standing credit to the foresight and fortitude of American business, and at this very moment, according to our Trade Commission, an important American Company, almost certainly in alliance with it, is surveying British Honduras, which was at one time a large producing area, with a view to re-establishing the industry there on a big scale. For Jamaica the United Fruit Company has meant the difference between plenty and penury. They go along taking up and developing as much of the land as a somewhat shortsighted policy enforced by penal taxation on estates over a certain size will allow them to do. Everywhere their plantations are well and scientifically cultivated and they have spent large sums of money in fighting against the Panama disease, from which the banana industry has suffered such serious losses. Moreover, wherever they have set their foot, they have seen to it that their labouring workmen are housed in a decent and sanitary fashion, which shows up unpleasantly by way of contrast the noisome and ramshackle hovels in which most of the peasantry live. In flattering testimony to the value of British service and American recognition, it may be mentioned that out of a white staff of some fifteen hundred employees of the Company only four, as I was told, were American citizens. The overseers of black labour are all Englishmen. This shows a delicacy of feeling and an impartiality of selection, such as we have not always been prepared to allow to the conduct of American corporations. There is no mistake about it, all the same, that the banana industry is something very like an American monopoly, look at it as we may, but it admirably illustrates both the strength and the virtues of Americanism in business. The exportation and marketing of bananas is almost exclusively in American hands, and it is a curious fact that nearly the whole crop that is harvested in Jamaica goes to Boston, whence about a sixth finds its way to Canada, whereas the English market is supplied almost entirely from the mainland. This is in no sense a political operation, but is dictated by the economic expediencies of the trade, which lay down the trade routes according to the best drawn scheme of operations in the market places of the world. Meanwhile, one hears not a thin, small voice, but a long-drawn wail, which must appeal to British ears, that whilst there are many independent planters who raise bananas of an excellent quality on their "pens," they cannot get them to the European markets, because the regular line of communications is controlled by the United Fruit Company and they carry no bananas but their own, in which case their cry is veritably "We take no bananas to-day" or any day. That seems a strong argument in favour of a subsidised service between the mother country and the West Indian Colonies, such as existed for forty or fifty years, both for passengers and goods. Lord Kylsant told me that the Royal Mail Steamship Company lost a million on it during the currency of their contract, and it will not be easy to obtain its renewal on adequate terms, but, meanwhile, the connecting lines have been largely cut, and, after holding the Caribbean Sea within the folds of the Red Ensign for two hundred years and more, we are now dependent to a large extent on tramps and tourist pleasure boats. Nor is it any real compensation that the fleets of ships which are employed in the new industry of boot-legging and rum running, which, I understand, to be among the strongest supports of prohibition in the United States, sail under the British flag. This question of sea communications is literally and truly a constant source of irritation and complaint, because, apart from the regular service once a fortnight from England to Jamaica, all communication between the islands has come to depend on the services of tramp steamers with the occasional call of great tourist boats which hail from the United States, even though sailing under the British flag. It was given me as an amusing instance of the attitude of the official mind in England that, when the extra battalions of the West Indian Regiment —which earned much credit and praise during the war—were about to be disbanded and sent by detachments to their home stations, the War Office issued an order that they were to be forwarded so far as possible by train. This gives rise to the laughter with a salt of bitterness that is akin to tears.

It should be borne in mind, too, that American influence in the West Indies is not limited merely to commercial transactions. It is due also to the travel habit of the American people. It has been said that you should form habits in youth in order to shed them in later years, but the mobility of the American citizen is a great national asset, that lasts as long as life itself. It is very difficult in these days of chance and change to run counter to the conveniences of life, and in exchange of goods and persons geography is on the side of the United States. We cannot, however, rest and be thankful in our present stage of colonial relations—at least we cannot rest and the Colonies have not much to be thankful for. The West Indies will not and cannot run themselves; they are formed *ex natura rerum* to be largely dependent, and, although they have all the bounty of the tropics in riotous prodigality, they have all their disabilities and ineptitudes. They cannot stand alone, and assuredly they cannot advance entirely unaided. The West Indies live under the charm of the lotus tree, but they suffer from its enervation and this makes them to some extent dependent on our help and guidance. Cut off to so large an extent from the big movements of men and things, they tend to develop an insularity comparable only to the number of their isles and islets. It struck me that the division of Jamaica into nineteen parishes had infected the colonists with a certain parochialism of outlook, which sometimes stands in the way of the co-operative commonwealth that the British Empire has to be, if it is to continue as a secure and stable reality in a world of illusions. It could not well be otherwise, and it is for us to supply the corrective and the stimulant from the power-house of British vitality by the broadcasting of British ideas and Imperial patriotism.

I am no stickler for forms of government and in the case of the British West Indies there is a great deal of wisdom in Pope's line, "That which is best administered is best," but there is no doubt that too little care and discrimination have been exercised by the Colonial Office in the selection of Governors and high officials for the various colonies. It is more or less true that half the evils of the world arise from putting three-cornered men into square holes and square men into three-cornered holes, and it is a case of mistaken ingenuity to prove that the fear of failure is not always justified. The classic case of Daniel Parke is an early example of what it means to test in this way the loyalty of the Colonies. In the "History of Colonel Parke's Administration whilst he was Captain General and Chief Governor of the Leeward Islands" by Mr. George French, printed and sold in London in 1717, it is narrated that "His Grace the Duke of Marlborough having sent Colonel Parke (his aide-de-camp) express to the late Queen with the first account of the glorious victory obtained at the Battle of Horstet, Her Majesty received the welcome news with great transports of joy and was graciously pleased as 'the messenger of such happy tidings to the nation deserved' to appoint him Captain General and Commander-in-Chief," of the Leeward Islands. He was no doubt a fine figure of a man, but he had been expelled from the House of Commons for bribery and had only escaped prosecution by the favour of a courtier; he had seduced the wife of an officer in the Guards, and he was, in general, a thorough-paced ruffian. His advocate says that "so far as was possible for a Lord Chancellor or Chief Governor in all causes to please each party, he had entirely gained the hearts of the people,' but because he was 'too honest' according to his friends, 'a set of men actuated by malice, envy, self-interest or such like devilish principles, imbrued their hands in his blood' with 'circumstances of cruelty and barbarity." In 1710 he was brutally murdered by a riotous mob headed by the 'Assembly men". . . "accounted the representatives of the people." There may be some doubt as to whether the measures that he meant to take against the French vessels were reasonable or not but he was an arbitrary and unpopular man, and he perished not so much for what he did as for what he was. As you scan the long list of West Indian Governors, you encounter at every turn the names of the proudest families of the British and Irish peerage, but the selection of their heads and members must have been on a par with the nepotism and corruption of the Whig oligarchy like so much else in the politics of the past. Of that in any form there is not much trace left now, but it may well be that our invariable course of official promotion in the colonial service, tempered still by occasional acts of political jobbery, does not always give the Colonies the best men available, I say nothing of the ideal men, who are mostly unavailable. There is a saying that in Jamaica the people receive everybody well except their Governors, and I am far from saying that it is easy to avoid criticism or even censure, if not as in Governor Parke's case by "Articles of Impeachment clandestinely forged" or even "Petitions of grievances, those lights of discontent and dark lanterns of rebellion," at least in newspaper articles and platform speeches. You will never satisfy everybody, but disappointments might be more easily avoided if appointments were subject to confirmation by a Cabinet Committee and if, as is now the case in a conferment of titles of honour by the Crown, a reasoned record and recommendation of every person to be entrusted with such office were published *urbi et orbi*. In the same way, I hold that the representative principle should be applied to the larger group of colonies, instead of always trusting to what Bismarck called "the spirit of the green table," for the pure—and it is pure—officialism of Downing Street is undoubtedly out of date. The jest applied without much reason to the great financial house of Baring—bearing, overbearing, and past bearing—represents more or less what the colonies feel about Whitehall, yet nobody speaking with knowledge can say that the time has yet come or will come for many a long day when Great Britain can scrap her colonial service or when her colonies would be better off if she did.

History never repeats itself except by analogy and to me, as an old Parliament man, the Parliamentary history of the West Indies, with all its moving pageant and all its tragic failures, is a warning written in letters of blood and tears against the facile and ignorant optimism which puts faith in tinsel imitations of our Parliamentary institutions in countries that are petrified by religious castes or a prey to savage feuds and hatreds. The Barbados and the Bahamas have a Parliamentary tradition carrying us back to 1625 and 1647 respectively and Jamaica only surrendered its Parliamentary privileges in 1866 to those whom Carlyle spoke of in "Niagara and After" as "a group or knot of rabid Nigger Philanthropists barking furiously in the gutter." It could not, however, have amounted to much in its latter days. Anthony Trollope has left us a description of a Parliamentary sitting which he attended, where the only Parliamentary bar was a drinking bar, which the members attended and where ribald talk went on without let or hindrance. Parliamentary representation of the West Indian families, like the Beckfords and the Gladstones, when such men as "Monk Lewis" had seats in the House of Commons and West Indian questions were discussed there with knowledge and sympathy has departed for good or ill. The old planter families have died or been bought out, although the "great houses" of Jamaica still bear witness to their opulence when, as Mr. Aspinall puts it, "sugar was king." Representation of that kind has gone beyond recall. On the other hand, just as the Federation of British Industries or the Miners' Federation have their nominees in the House of Commons, so by reviving the wholesome and historic principle of virtual representation, the Associated Chambers of Commerce of the British West Indies and the West India Committee ought to have representative members in Parliament. I can only hope that some of them are among the candidates at the forthcoming General Election.

Then, I again put forward a plea for the constitution of the office of High Commissioner for the British West Indies to take his place in the official world immediately after the High Commissioners for the self-governing Dominions and before, say, the Agent General for the Malay States. In the eighteenth century all the important colonies had their agents at the seat of Empire to transact their business and advocate their claims, for it must never be forgotten that the West Indian islands loomed much larger in the eyes of Old England than they do to-day. Byron's words applied to them in full:

"I longed to see the isles that gem
"Old Ocean's purple diadem.
"I sought by turns and saw them all."

Few English people seek to see them to-day, and, did they seek, they would find the travelling facilities quite insufficient. It is said that the want of confederation or even of co-operation among the West Indian islands makes any joint agreement for the appointment, still more for the payment, of such a high officer of state unlikely, if not impossible. It may be so, but federation will not come into being unless it hangs on a political issue and seems to promise a general advancement all along the line.

Constitutional agreements which are conceived by philosophers and made in the senate seldom fulfil the hopes of their authors. Mr. Gladstone spoke of the constitution of the United States as the greatest achievement of human wisdom that ever came full-fledged from the mind of man, but this is, like so many of the old fallacies of constitutional government, quite a mistaken view. Mr. Beck, the Solicitor-General of the United States, has recently explained in a course of lectures before the Inns of Court in London that the constitution of the United States was made up of a series of borrowings and extracts from the varying constitutions of the different colonies, who first came together in a federated state for the purposes of defence. In fact, in a sense, the constitution of the United States is one big "appropriation clause" from the British Constitution, as broken up in the 17th and 18th centuries among the plantations of America.

To make a constitutional consolidation of West Indian interests will be no easy task, but to begin by having a High Commissioner who can embody the proud traditions of these old colonies would be characteristically British and eminently business-like. He would be at once a political envoy and a commercial agent, and that is not a bad combination in these days, when for want of trade the nations perish. Who represents the West Indies at this moment in the Colonial Office or in the City is wrapt in mystery, but probably you might discover him after a walk down endless corridors in one of the labyrinths of Whitehall and the labyrinth of the office is, to vary Tennyson, the labyrinth of the official mind. When I was young in Parliament, more than thirty years ago, I was appointed to the Royal Commission on Civil Establishments of which Lord Lingen was a member. You may never have heard of Lord Lingen, but for a generation he had been head of our Civil Service as Permanent Secretary to the Treasury, and Lord Beaconsfield had said of him, "the real Governor of England is Mr. Lingen." He was almost unknown to fame, and he hardly figures even in the history of our own times. If you wished to find the Governor-General of the West Indies, you might have to pace the passages of the Colonial Office until you came to a small room indifferently lighted and there you would find in the person of an excellent head of a department the power behind the throne. Who he may be at the moment I do not know, but I am certain that he is a public servant of the highest character. The Tite Barnacles of Dickens's novels were all good men, in their way, but the civil servant of our day is something much better—and you may rely upon it that he is a patriot and a gentleman. Yet, for all that, I do not believe that the Colonial Empire, excluding the self-governing Dominions, can any longer be run on the labyrinthine principle. Hole and corner administration is no longer sufficient for its purposes, and the grotesque mistakes that are sometimes made in the appointment of Governors and Lieutentant-Governors to the Crown Colonies are all due to the labyrinth of the official mind and not to any practical joke department of the State. The British Empire may not be altogether a garden city, for it has its mean streets and its slum areas, but it is assuredly a city of many gardens, "from Greenland's icy mountains to India's coral strand," and its gardens require affectionate understanding and sympathetic tending. "We must cultivate our garden," as Candide tells us, or it will pass to other hands.

The Imperial Conference which has just, to use the official phrase, concluded its deliberations, did something to remove the reproach that in the competition and clash of imperial interests the West Indies were always forgotten. The Under Secretary of State for the Colonies was advised by a Committee on which Sir Edward Davson, an excellent nominee, spoke for the West Indies. It was a step in the right direction, but I hope that at the next Imperial Conference the West Indies will have separate and individual procuration. At the Economic Conference, which was rather a different incarnation of the main Conference than another body, the stabilisation of the existing preference of one-sixth or 4s. 3½d. per cwt., being nearly a half-penny a pound on refined sugar grown within the Empire was recommended for a period of ten years, and the extension of the fruit clauses, although not intended especially for the benefit of the West Indies may have a beneficial effect on their agricultural production. I quote the report of the conclusions arrived at: "It is not possible at present to offer an increase in this preference, but His Majesty's Government are ready to guarantee that if the duty is reduced the preference shall for a period of ten years not fall with it, but be maintained at its present rate of nearly ½d. per pound so long at least as the duty on foreign sugar does not fall below that level. At present dried fruit, figs, raisins, and plums (including apricots), are dutiable at the rate of 10s. 6d. per cwt., if from foreign countries, and enjoy if of Empire origin a preference of one-sixth, i.e., of 1s. 9d. per cwt. It is proposed to admit these goods free of duty from the Empire so that Empire raisins, figs and plums will enjoy a preference of 10s. 6d. per cwt." Unfortunately, owing to the exigencies of party warfare, on the principle of the in and out system or the battles of the kites and crows, a preferential tariff, which includes sugar, has become a plank in the party platform to be alternately attacked and defended, by walking the plank or otherwise. The Cobden Club is clearing its trenches of the debris and the dust heaps of the old struggle of a hundred years and is once more using, as the French had to do in the Great War for want of heavy artillery, the mortars that did duty in the Crimean War. I cannot help expressing my regret that the old cry "What is the Empire to Battersea?" should again echo through the land.

In respect to communication by sea and air, under the sea and above the air, the decisions of the Imperial Conference do not carry us much further. The conditions of transport to the West Indian islands are regrettable in the extreme, and they cannot be set right unless the Imperial Exchequer is prepared to give more liberal terms to British shipping. It will remain nothing short of a scandal that the freight ships of the banana trade should be in the hands of an American Corporation, however enterprising, and that except for tramp steamers it is virtually impossible to travel at all or with reasonable speed and regularity in any case between one colony and another. So far as British shipping goes, the sea routes of the Empire in the West, where our flag was supposed to proclaim our home, are derelict and forsaken.

In regard to telegraphic cables, some progress was reported, of which the particulars have several times been stated, but the rates still present a picture of strange and capricious variation. To the Bahamas via Florida, the press rate from this side is 1/1½d. a word, whereas to Jamaica via New York-Havana it is only 8½d. To British Guiana via Colon it is 3/3½d., but via Key West it is 1/0½d. All these differences are very picturesque but the result is, in regard to such a colony as British Honduras, that all the news service is forced on to the American wires or wireless.

When we turn to the latter branch of intercommunication there is nothing to report. In the part of the world where wireless telegraphy is most wanted, we continue to accept the ridiculous plea that the atmospherics are unsuitable, although Senator Marconi tells us that is a difficulty that exists only to be surmounted.

It is profoundly true in such matters that where there's a will, there's a wire, and it is the will to power, not the skill to power, that is still wanting and to seek.

Aviation has had some share of the attention of the Economic Conference, and it is to be hoped that it will no longer be the case that the only flying service over the Caribbean is that between Miami on the coast of Florida and the Bahamas, which has been carried on regularly for some three or four years. If there was an archipelago which lent itself to an air service it is surely the West Indies. The air ship routes contemplated by Commander Burney may not touch on Central America, but it is well worth the Secretary of State for Air taking into consideration the fine opportunities that are offered in this sphere of British influence. The West Indies suffer from a certain lethargy, which does not amount to slackness, if left by themselves. It was well expressed in a sentence of a complaint from the island of Nevis so far back as in the days of good Queen Anne:—"The people of Nevis expect the Queen should do everything for them, though they do not endeavour to help themselves." Climate and environment always have their effect on national character and conduct, as Buckle explained in so large a way in his "History of Civilisation" seventy years ago. So mote it be, the archaic formula has it.

I cannot finish this subject better than by a quotation from J. A. Froude, who had an easy command of glowing language which is beyond my capacity: "At one time the West Indian Colonies had been more to us than such casual seedlings. They had been regarded as precious jewels, which hundreds of thousands of English lives had been sacrificed to tear from France and Spain. The Caribbean Sea was the cradle of the Naval Empire of Great Britain. There Drake and Hawkins intercepted the golden stream which flowed from Panama into the exchequer at Madrid, and furnished Philip with the means to carry on his war with the Reformation. The Pope had claimed to be the lord of the New World as well as of the Old, and had declared that the Spaniards, and only Spaniards, should own territory or carry on trade there within the tropics. The seamen of England took up the challenge and replied with cannon shot. It was not the Crown, it was not the Government, which fought that battle, it was the people of England, who fought it with their own hands and their own resources. Adventurers, buccaneers, corsairs, privateers, call them by what name you will, stand as extraordinary but characteristic figures on the stage of history, disowned or acknowledged by their sovereign as suited diplomatic convenience. The outlawed pirate of one year was promoted the next to be a governor and his country's representative. In those waters the men were formed and trained who drove the Armada through the Channel into wreck and ruin. In those waters, in the centuries that followed, France and England fought for the ocean empire, and England won it—won it on the day when her own politicians' hearts had failed them, and all the powers of the world had combined to humiliate her, and Rodney shattered the French fleet, saved Gibraltar, and avenged York Town. If ever the naval exploits of this country are done into an epic poem—and since the Iliad there has been no subject better fitted for such treatment or better deserving it—the West Indies will be the scene of the most brilliant cantos. For England to allow them to drift away from her because they have no immediate marketable value, would be a sign that she had lost the feelings with which great nations always treasure the heroic traditions of their fathers. When these traditions come to be regarded as something which concerns them no longer, their greatness is already on the wane."

DISCUSSION.

The CHAIRMAN (Lord Askwith) thanked Lord Burnham for the admirable paper which he had read. Referring to the allusion to the peaceful penetration of the United States with the passive assistance of British apathy, he felt that in our dealings with our Dominions and our Colonies we had come to a new era when by co-operation and working together there might again come a time when islands such as the West Indies would be looked upon as the jewels of our Empire. Lord Burnham had touched on much: there was much that he had had to leave out. He had not even alluded to Jamaica rum, an important thing in the last war and in many other wars before. He had not spoken of the woods of the islands, nor of the asphalte and other oil products, which as a trade were thriving in Trinidad, an island more connected with the mainland than the other islands, but included among the West Indian islands. The rest of the islands were geologically supposed to be the tops of mountains, which originally were connected with Florida by land. Including Cuba, their extent was about 100,000 square miles, as compared with an area of

12,000 square miles of the British Isles. By that comparison one could appreciate the large extent of territory comprised. That territory possessed many kinds of products, although they were "samples," amongst which it might be unwise to mention snakes, adders and insects. There was much to be seen by tourists who could travel from island to island. Captain Marryat, in his splendid novels, had, with that power of description which he possessed, described in a marvellous way the scenery of Barbados and other islands.

Sir Edward Davson offered his congratulations to Lord Burnham on the very graphic and eloquent paper which he had read. He also congratulated the West Indies on having been able to enlist the sympathy and interest of Lord Burnham, who was one of the busiest men in the Empire, a great patriot, and one whose name stood for all that was best in journalism. It was indeed a very happy circumstance for the West Indies that he had been induced to spend a few months last year in those parts, and it was to be hoped that at some time in the near future he would be able to complete his tour of the islands. Meanwhile, he had already left his mark in the West Indies by the formation of a West Indian Branch of the Empire Press Union. If that organisation could lead to any improvement in the press news of the West Indies, it would have done a great work in helping that part of the Empire to understand what was going on at home better than they had done in the recent past. An enterprising editor in the Island of Trinidad had put up a wireless station of his own from which he was able to obtain news which was sent out to the World, and was thus relieved from the necessity of being dependent on news which usually emanated from American sources. The Colonial representation which had been obtained at the Economic Conference was in a large measure due to the work of Lord Burnham, who, in an eloquent speech in the House of Lords, had put forward the need for Colonial representation very forcibly. The Resolutions of the Economic Conference, if confirmed, would prove of very great benefit to the West Indies, that with regard to the stabilised price of sugar being most important. The West Indies and British Guiana were most anxious to show what they could do in the way of sugar production. This country consumed 1,800,000 tons of sugar a year, and British Guiana claimed that given favourable conditions it could produce at least half that amount. There were other Resolutions affecting the welfare of the West Indies, and it was unfortunate from the West Indian point of view that these matters had become the subject of party strife in politics. He was not going to touch on present day politics, because he did not think that was wanted at that meeting, but he hoped, whatever might be the outcome of the forthcoming General Election, that the Resolutions passed at the Economic Conference would be confirmed. It had been intended to send to the West Indies a party of Members of Parliament; unfortunately at the present moment the members of this proposed party were no longer Members of Parliament, and did not know whether they would be re-elected. It was to be hoped that if the party had to be postponed, it would merely mean a postponement and not an abandonment. He did not see why the West Indies should not have a High Commissioner. The title "High Commissioner" was in fact used exclusively with reference to the Dominions and India, but whatever title was best could be used, that being unimportant. One difficulty was that of getting a definite opinion from the West Indies on the subject. He thought Jamaica approved of the idea, Barbados did not altogether approve; Trinidad considered that another scheme might be adopted by which the West India Committee could do the necessary work; British Guiana desired to have a Trade Commissioner, or whatever he might be called, entirely to itself. It was obvious, therefore, that before such an appointment could be made there was a good deal of work to be done in bringing together opinion in the West Indies. He was also rather afraid that if, and when, the gentleman was appointed there might be some difficulty as to who was to control him. He might have about six masters, and when one had six masters, one had not any master at all, while possibly there might be a good deal of jealousy if he advocated the claims of one Colony in preference to those of another. But he was sure Lord Burnham would say these were difficulties which only existed in order to be overcome, and he hoped the attention of the West Indies would be given to these very important matters.

Mr. R. Rutherford (Chairman of the West India Committee) expressed the thanks of all interested in the West Indies for the very interesting paper which had been read. He hoped Lord Burnham would repeat his visit to the West Indies.

Mr. H. Medlicott Rumball said he intended to visit the West Indies. He did not think anybody could have read the papers during the last few years without recognising what a great debt of gratitude was due to Lord Burnham, who had the interests of the Empire so much at heart. Looking back at the condition of London when he was a young man, and considering the changes which had since taken place, he asked himself: Whither are we tending? It was men like Lord Burnham who could lead and advise. The West Indies had glorious traditions; their history was the story of great achievements, and he asked why the same things were not taking place to-day. Surely Englishmen had the same amount of enterprise as Americans. Means of communication were the basis upon which development in the West Indies must proceed. Surely the trade of this country could support a line of British steamers to the West Indies. The mother country must give a little help to tropical products, which we did not, of course, produce ourselves. We badly needed sugar, which was at a high price. Why should we not help the Colonies to produce that sugar?

Viscount **BURNHAM** thanked those who had spoken for the kind things they had said; they had attributed to him more than he could lay claim to. In the House of Lords he had been glad to break the silence as to the West Indies which had existed, he thought, for nearly 25 years. Certainly in both Houses of Parliament the West Indies had not received the attention which they deserved, and that was especially a matter for comment in the House of Lords, where there were great opportunities for raising questions. As Chairman of the Executive Committee of the Empire Parliamentary Association, whose membership included nearly all the Members of Parliament in the Empire, he had thought it of the utmost importance to urge upon his colleagues the desirability of sending out a party of Members of Parliament to the West Indies, though he could not claim to be the originator of the idea, which had been warmly taken up, and, as far as he knew, had not been abandoned. It had been intended that a delegation of Members of Parliament and their ladies consisting of 40 persons should go out. He had seen many of the members of that delegation, and they had been anxious that their going should not depend on re-election to Parliament, and he had felt that if there were a substantial number re-elected—at least three quarters—perhaps the West Indies would not feel aggrieved that there were a small minority who had not secured re-election and would accept their nomination as from the last Parliament. Such a personal tour would be of great benefit, and as a consequence a great deal more would be heard in the House of Commons about the Caribbean than had been said during the last 30 years.

DR. J. A. VOELCKER in seconding a vote of thanks to Lord Burnham, proposed by the Chairman, said the paper had been one full of life and fire, and, coming from such an authority, would carry great weight and draw more attention to the needs of our Colonies, and the West Indies in particular. He personally had never been to the West Indies, though he had had to do with those Islands, chiefly in regard to agriculture. He had heard a great deal of the labours of scientists who had gone out to the West Indies and worked under great difficulties. Greater attention was now being given to agriculture than formerly. Not long since the Colonial Office had moved with a view to the establishment of a college in the West Indies, and a recent Member of the Council of the Society, Professor J. B. Farmer, of the Imperial College of Science and Technology, had made a tour of the islands in order to see what the state of the different agricultural industries was. As an outcome of that mission a number of appointments of botanists, chemists, entomologists, &c., had been made, and there was hope that in the future, whatever had been the position in the past, more attention would be given to the needs of agricultural industries in those parts. It was not a matter which concerned merely the West Indies. In England a large number of scientists were being trained in the Imperial College of Science and elsewhere; very few of those students would be able to get appointments in this country, and there arose the problem as to how their energies were to be utilised. There was a promising outlook in the West Indies and similar places where there were many questions unsolved with regard to plant physiology, the diseases of plants, the attacks of insects, which in many cases threatened ruin, and the removal of which would be of great advantage.

The motion was carried unanimously and the meeting then ended.

MR. ALGERNON ASPINALL, C.M.G., writes:—

Owing to the receipt of several urgent cablegrams from the West Indies which required immediate attention, I was at the last minute prevented from attending the meeting of your Society on November 27th, and of listening to Lord Burnham's Paper, which I have read with much interest.

All connected with the West Indies should be grateful to Lord Burnham for the close and practical interest which he has taken in West Indian affairs since his visit to Jamaica; and perusal of his Paper shows clearly that he has dipped deeply into the romantic history and literature of our oldest group of Colonies.

One has heard of the disastrous attempts to federate the scattered islands in the group, which culminated in disturbances in Barbados in the seventies of last century, but I confess that I was quite unaware that this was to be a preliminary step towards the alternative of a federal republic or annexation to the United States of America, a policy which I am glad to note that Lord Burnham denounced in no measured terms. It is monstrous that any Englishmen and English newspapers should suggest the transfer of our Colonies in the Caribbean Sea, which have aptly been termed the "Cradle of the Royal Navy," to a foreign flag!

Lord Burnham in his Paper referred to lack of British enterprise and initiative in the West Indies. In this connexion it must not be forgotten that though Americans have "put it over" us by developing the banana industry in Jamaica (which they have done with such remarkable efficiency), British capital has been forthcoming recently for development of the diamond industry in British Guiana, for the acquisition and maintenance of Gray's Inn Sugar Estate in Jamaica, and for the development of the petroleum industry in Trinidad (in which at least £6,000,000 is invested) and that at the present moment negotiations are proceeding for the establishment with British capital of a Jamaica Sugar Syndicate under the auspices of the Duke of Atholl and Lord Invernairn, for developing large areas in the South Eastern part of Jamaica under sugar and other forms of cultivation. Moreover, quite lately a loan of £1,000,000 was successfully floated in this country for British Guiana.

I mention these few examples to show that British capital is available for the West Indies where substantial and businesslike propositions are concerned.

The suggestion that a High Commissioner should be appointed for the West Indies is an interesting one; but I fear that Lord Burnham has hardly appreciated the difficulties which exist in harmonising the divergent views and interests of the scattered group of islands before an official can represent the United West Indies. Meanwhile the offer of the West India Committee to conduct a trade commissioner service for the colonies concerned for a nominal annual payment remains open, and with the closing of the Exhibition Galleries at the Imperial Institute imminent, the question of housing the West Indian economic collections there will have to be considered.

Lord Burnham correctly diagnosed the situation generally when he attributed the present insularity of many of the units forming the British West Indies, to lack of communications. Mr. Edward Wood, after visiting the Colonies last year, stated that federation of the West Indies must be "a plant of slow and tender growth." With that statement I entirely agree, and would add that the best fertiliser for the plant would be improved and cheaper inter-insular communication by means of steamships, cables and wireless, and one cannot help feeling that it would pay in the long run if an official could be appointed of the calibre of a Milner or a Cromer, who could constantly tour the islands themselves and preach the advantages of unity and combination.

In conclusion, I should like to express my indebtedness to Lord Burnham for the assistance which he has recently been affording to the British West Indies in many ways, and notably in the direction of securing publicity for their many attractions and the ventilation of their numerous problems.

MR. R. RUTHERFORD writes :—

If I had known that I was to be called upon to speak on the occasion of the meeting on November 27th, I would certainly have said a little more than I did.

I would have liked, for example, to say something about the Imperial College of Tropical Agriculture, which promises, I think, to be one of the most important pieces of constructive work to be carried out by the British West Indies for many years. With headquarters at Trinidad, it will cater for the Empire as a whole in the direction of providing facilities for education in Tropical Agriculture and allied sciences, and what to my mind is, if anything, even more important, practical research.

The College is now recognised as a training centre by the Empire Cotton Growing Corporation, which has sent several students to it, and I hope that Lord Burnham may be induced some day to pay a visit and inspect its well-equipped laboratories.

As Chairman of the West India Committee, I would like to have said something also about the proposed Parliamentary Delegation to the West Indies, the arrangements for which are being carried out by the Committee in co-operation with the Empire Parliamentary Association, the Governments of Trinidad and British Guiana and the Jamaica Imperial Association, which suggested that Lord Burnham on the occasion of his visit to the West Indies earlier in the year, might be accompanied by representatives of the Parliament of the United Kingdom.

PRODUCTION OF RESIN BY THE HARZGESELLSCHAFT.

The annual report of the Harzgesellschaft shows that in the year 1922, 127 metric tons of resin were extracted. The sources were as follows :—55,000 kilos from leased land, 51,000 kilos from the Prussian Staatsforstverwaltung (Prussian Bureau of Forestry), and 21,000 kilos from the Bavarian Staatsforstverwaltung. From this amount 88,000 kilos of finished resin and 20,500 kilos of turpentine were obtained.

The cost of production was considerably below market prices and a large profit was made, enabling the company to declare a 50 per cent. dividend and to put aside 1,500,000 marks for scientific research work. Negotiations were made with a view to obtaining new leases from the Prussian and Bavarian Staatsforstverwaltung for the two new fiscal years—one a short one from January 1st, 1923, to March 31st, 1923 and one from April 1st, 1923, to March 31st, 1924. An agreement for this purpose was signed in January with the Prussian Ministry of Agriculture, but negotiations with the Bavarian Staatsforstverwaltung did not materialize, so that the extraction of resin in Bavaria will only be undertaken by the head foresters, who, in turn, will sell the product to the Deutsche Harzgesellschaft. However, contracts for deliveries were signed last year, and both the Bavarian Staatsforstverwaltung and the Prussian minister of agriculture, domains, and forestry have given instructions to the places in question to continue the extraction of resin as quickly as possible. An agreement with Saxony is pending. The production from this part of the country is limited, owing to the scarcity of pine.

It appears from a report by the United States Vice-Consul at Frankfort-on-Main that the Deutsche Harzgesellschaft has enlarged its works and has leased new ground. At present it has 1,500 hectares (3,706 acres) at its disposal, with a sufficient number of trained employees in view. The company anticipates extracting 800 kilos of raw resin per hectare, which contains about 70 per cent. pure resin, 17 per cent. turpentine and 13 per cent. waste. Private owners have been approached with a view to obtaining leases for new resin ground and it is hoped that they will, in one way or another, lend assistance to the industry. The outlook for the new year is quite favourable and an increased production of resin by the Harzgesellschaft is anticipated.

CHICLE INDUSTRY IN BRITISH HONDURAS.

Chicle is a crude gum used as the base in the manufacture of chewing gum. The best quality of chicle is produced in the States of Yucatan and Campeche in Mexico, in Guatemala, and in the northern half of British Honduras. This gum is derived from the sapodilla trees which grow in the mahogany forests. The average yield is from two to six pounds per tree, the maximum yield for certain regions having been stated at 25 pounds, but in Mexico and in British Honduras the yield of gum per tree is reported to have reached as high as 61 pounds.

The chicle season extends from the first of July to the end of June. In July, the beginning of the rainy season, the trees are tapped for the gum, which is then boiled, kneaded, and moulded into blocks weighing 30 pounds each, and sent to the port of shipment. Practically all of the chicle from the three principal producing countries is shipped from the port of Belize in British Honduras. According to a report by the United States Consul at Belize, the first shipment of chicle to the United States from British Honduras was in 1892. Within a few years the industry in British Honduras had assumed important proportions and has continued to develope to such an extent that it now holds first place in respect to the value of exports and as a source of revenue to the Government on account of the export duty. In 1896, 925,199 pounds of chicle were exported from British Honduras, and in 1922 exports amounted to 2,032,102 pounds. The highest peak in the interval was reached in 1920, when 3,690,641 pounds were exported.

A number of the larger American manufacturers of chewing gum have established agencies in Belize in order to buy, test, and ship the gum to the United States. The price of chicle has dropped from an average of 2s. 11d. per pound in 1920 to an average of 2s. in 1922. The quality of the gum, however, has improved notwithstanding the decrease in price. During the war and immediately thereafter, owing to the high prices asked for chicle, many of the manufacturers of chewing gum experimented with other ingredients in the hope of finding a satisfactory substitute for chicle. A cheaper gum from the Far East was used with a degree of success, but no substitute has been found which equals chicle in value.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, DECEMBER 17.. University of London, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C., 4 p.m. Mr. F. W. Twort, "The Influence of Environment on the Life of Bacteria." (Lecture IV.)

Geographical Society, 135, New Bond Street, W., 8.30 p.m. Rev. W. Weston, "The Influence of Nature on Japanese Character."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 7 p.m. (Graduates' Section). Mr. F. E. A. Manning, "The Management of a Sand and Flint Quarry."

Engineers, Junior Institution of (North-Western Section), at the Manchester Geographical Society, 16, St. Mary's Parsonage, Manchester, 7.15 p.m. Mr. H. M. Knight, "The Application of Fuel Oil to Modern Industry."

British Architects, Institution of, at the Royal Society of Medicine, 1, Wimpole Street, W., 8 p.m. Mr. R. Unwin, "Higher Buildings in relation to Town Planning."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal meeting.) Discussion on "Students in Electrical Undertakings."

Textile Institute (London Section), 38, Bloomsbury Square, W.C., 7.30 p.m. Discussion on "Comparative Methods of Testing Textiles."

East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Sir Alfred Chatterton, "The Future Development of Indian Industries."

TUESDAY, DECEMBER 18.. Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m.

University of London, King's College, Strand W.C., 5.30 p.m. Baron A. F. Meyendriff, "The Russian Constitution of 1905."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Mr. J. Stuart, "Tshaka, the Great Zulu Despot."

Civil Engineers, Institution of, Great George Street, S.W. 6 p.m.

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. W. Seilar, "A Basis for the Explanation of Marine Gear Troubles."

Transport, Institute of, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C., 5.30 p.m. Mr. H. T. Chapman, "Arterial Roads and their Effect upon Transport."

WEDNESDAY, DECEMBER 19.. University of London, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C., 4 p.m. Mr. F. W. Twort, "The Influence of Environment on the Life of Bacteria." (Lecture V.)

Metrological Society, 49, Cromwell Road, S.W., 5 p.m.

THURSDAY, DECEMBER 20.. Photographic Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Mr. Will Day, "Kinematography and its Antecedents." (Inaugural Meeting of the Kinematography Group.)

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. (1) Mr. W. E. Downey, "The Relation between the Glow of Phosphorous and the Formation of Ozone." (2) Mr. T. M. Lowry, "The Origin of Mutarotation and the Mechanism of Isomeric Change." (3) Messrs. F. Challenger and F. Pritchard, "The Action of Inorganic Haloids on Organo-metallic Compounds." (4) Messrs. J. F. Wilkinson and F. Challenger, "Organo-Derivatives of Bismuth. Part VII. Iodo- and Nitro-Derivatives of Triphenylbismuthine."

London County Council, at the Geffrye Museum, Kingsland Road, E., 7.30 p.m. Major A. A. Longden, "The Modern Home."

Mechanical Engineers, Institution of (Local Section), Engineers' Club, Albert Square, Manchester, 7 p.m. Prof. A. H. Gibson and Mr. H. W. Baker, "Exhaust Valve Cylinder Head Temperatures in High-Speed Petrol Engines."

(Local Section), University Buildings, Edgbaston, Birmingham, 7.30 p.m. Mr. H. C. Young, "Engineering Uses of Rubber."

Mining and Metallurgy, at the Geological Society, Burlington House, Piccadilly, W. 5.30 p.m.

Journal of the Royal Society of Arts.

NOTICES.

COUNCIL.

Competition of Industrial Designs.

A meeting of the Council was held on Monday, December 10th ; Present :—

Lord Askwith, K.C.B., K.C., D.C.L. (in the Chair) ; Sir Charles S. Bayley, G.C.I.E., K.C.S.I. ; Sir William Henry Davison, K.B.E., D.L., M.P. ; Mr. Edward Dent, M.A. ; Mr. P. M. Evans, M.A., LL.D. ; Rear-Admiral James de Courcy Hamilton, M.V.O. ; Major Sir Humphrey Leggett, D.S.O., R.E. ; Sir Philip Magnus, Bt. ; Dr. William Henry Maw, M.Inst.C.E.; Sir George Sutton, Bt. ; Mr. James Swinburne, F.R.S. ; Mr. Alan A. Campbell Swinton, F.R.S. ; Mr. Carmichael Thomas ; Dr. J. Augustus Voelcker, M.A., Ph.D. ; Sir Frank Warner, K.B.E. ; and Sir Philip Watts, K.C.B., LL.D., F.R.S. ; with Mr. G. K. Menzies, M.A. (Secretary of the Society).

The Regulations for the first Annual Competition of Industrial Designs, to be held at the Victoria and Albert Museum in June, 1924, were finally approved. On this occasion competitions will be held in the following sections :—Textiles, Furniture, Book Production, Pottery and Glass, and Miscellaneous. Over £1,000 will be offered in Travelling Scholarships and Money Prizes in the various sections, and the Society's Diploma will be conferred on any candidate whose work reaches a very high standard of artistic ability and shows practical knowledge of the materials and processes of his trade. Copies of the Regulations can now be obtained on application to the Secretary.

Adjudicators for the Swiney Prize were appointed.

Arrangements for papers to be read in the last part of the session were further considered.

Other formal business was transacted.

SIXTH ORDINARY MEETING.

Wednesday, December 12th, 1923 ; Sir Aston Webb, K.C.V.O., C.B., P.R.A., in the Chair.

The following candidates were proposed for election as Fellows of the Society :—

Alexander, Philip, London.
Fletcher, John Kyrle, Newport, Mon.
Graydon-Bradley, Mrs. E., London.
Margerison, William Joseph, Leeds.
Rhead, Frederick A., Wolstanton, Staffs.

The following candidates were duly elected Fellows of the Society :—

Avram, Möis H., New York City, U.S.A.
Davis, Neville Ryland, London.
Duitz, Emile A., Amsterdam, Holland.
Gray, Roland, Boston, U.S.A.
Lang, Reginald, Plymouth.
Morrow, George Leslie, Berkhamsted, Herts.
Rayner-Smith, Percy, London.
Williams, Lennard, Tilehurst, Berks.
Williams, Stephen Miller, Arkansas, U.S.A.

A paper on "The Preservation of Historic Buildings and Ancient Monuments" was read by Sir Frank Baines, C.V.O., C.B.E., Director of Works, H.M. Office of Works.

The paper and discussion will be published in a subsequent number of the *Journal.*

DOMINIONS AND COLONIES SECTION.

Monday, December 17th, 1923 ; The Earl of Airlie, M.C., in the Chair.

A paper on "Empire Settlement" was read by Mr. Wm. C. Noxon, Agent-General for Ontario.

The paper and discussion will be published in a subsequent number of the *Journal.*

MANN JUVENILE LECTURES.

Under the Mann Trust a short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, 2nd and 9th January, 1924, at 3 p.m., by Dr. William Arthur Bone, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology, on "Fire and Explosions." The lectures will be fully illustrated with experiments.

A lecture will also be given on Wednesday, January 16th, at 3 p.m., by Mrs. Julia W. Henshaw, F.R.G.S., Croix de Guerre, entitled "Among the Selkirk Mountains of Canada (with ice-axe and camera)." The lecture will be fully illustrated with hand-painted lantern slides.

Special tickets are required for these two sets of lectures. A sufficient number to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply to the Secretary at once stating for which lectures the tickets are required.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

WEDNESDAY, NOVEMBER 28TH, 1923.

LORD DAWSON OF PENN, M.D., B.Sc., F.R.C.P., in the Chair.

THE CHAIRMAN said that the audience was to enjoy a disquisition by a master of his subject on the scientific application of three great natural agencies—namely, air, water, and sunlight, which belonged to man's environment (though the experience of the last few days might create a fear that light was no longer one of them). The beneficial effects of climate, sunshine, and life by the seaside, belonged to the common experience of mankind. What had not been apparent was the how and the why of their actions, so variable in their effects on different people. They had only to try and imagine the world without sunshine to bring home to their minds not only the necessity of the sun to human existence, but the part it played in giving activity, joy, and laughter. All this had been known and applied in a loose empirical way for ages. Then came method and scientific application. For bringing intensive sunshine and air into a system of treatment a great debt was due to Dr. Rollier, who, at his clinics at Leysin, amidst beautiful surroundings and abundant sunshine, brought healing and happiness to hundreds every year. Then in our own country arose the late Sir William Treloar, a man of vision, hope, and heart, who showed the supreme quality of youth in age, and for whose life they were grateful, and for whose death sorrowful. Treloar conceived the idea of treating child cripples, so many of whom were tuberculous, by air and sunlight, and he had the good fortune to press into his service Sir Henry Gauvain, who combined scientific distinction with skill in administration. It required faith and courage to organize such a scheme in our country, where the sun showed itself so fitfully, and sometimes so little, and where winters were apt to be gloomy and sunless. But it had been accomplished, and with that accomplishment under the climatic conditions of this country the proof of the success of the treatment was the stronger. Let anyone who had not already had the pleasure of doing so pay a visit to Alton or Hayling Island. There they would see sickly children made whole, helpless children made useful, and children so uniformly happy and mirthful as to bring sunshine to all who saw them. The great results which had followed the systematic use of sunlight and fresh air in this and other countries had stimulated research as to the means whereby light exercised these beneficent actions. The ultra-violet rays would appear to raise the resisting and fighting power of the blood against infection, thereby opening up a possible field of successful treatment of many diseases at present baffling. But here caution was necessary, for already there had been ample evidence to show that any application of such treatment beyond what careful research had indicated was likely to inflict harm and not good. In short, like all effective weapons, they could be powerful alike for healing and for destruction. The influence of light upon the growth and vigour of the young had yielded the most fascinating results. Sir Henry Gauvain would give his experience, and the brilliant researches by workers sent out by the Medical Research Council to Vienna to inquire into the influences of light on the cure of rickets stood out as landmarks in our knowledge. If he allowed himself to indulge in prophecy he would say that both in the region of diagnosis and treatment there was no direction in which the power of knowledge over health and disease would be more prolific of results within the next few years than in the scientific utilization of the action of radiations and the action of air. When the world realized the power of daylight in the maintenance and restoration of health, was it to be supposed that public opinion would longer suffer tens of thousands of town dwellers to be immersed in eternal gloom to the detriment of their health and energies and to the saddening of their lives? When once the gain in effectiveness and happiness afforded by light and air was understood, smoke abatement would be insisted upon, the demand for clean air would give such an impetus to investigation that a way out would be found against the smoke nuisance which would furnish the prime necessity of health without any undue crippling of industry; and just as years ago a great movement of public health gave us the blessings of pure water, pure food, and good drainage, so the public would demand and support a like campaign for the equally vital blessings of light and air.

The paper read was:—

THE EFFECT OF SUN, SEA AND OPEN-AIR IN THE TREATMENT OF DISEASE.

BY SIR HENRY GAUVAIN, M.A., M.D., M.Ch.,

Medical Superintendent, Lord Mayor Treloar Cripples' Hospital.

It is perhaps of academic interest to note that sunlight has been used spasmodically and to some extent in the treatment of disease from the earliest times. There has long existed an almost instinctive recognition of the value of sunny localities and sunny climates in the treatment of the sick, particularly during convalescence. But for real practical purposes the solid value of light treatment commenced with Finsen, and the sun cure, as we now recognise it, only dates from this century, and owes much for its systematic application to Rollier, its first really enthusiastic advocate, who opened his first clinic in Leysin in 1903.

Quite unconscious of Rollier's work I first noted the value of sunshine in 1908, started treatment in 1909, and became really enthusiastic during the fine summer of 1911, since which date it has been employed systematically for every suitable patient at Alton. I first heard of Rollier and his methods in 1912. I mention this because it is of historic interest to note that the sun cure was evolved independently in this country and, as far as I am aware, first utilised in England at Alton. Comparatively little interest was evoked until 1921, when the most wonderful summer in living memory, coupled with increasing advocacy of an extended summer time, compelled universal notice in England of the effects of abundant sunshine, and directed an almost embarrassing attention to our work at Alton. Quite suddenly this method of treatment attracted widespread notice and nobody was more surprised than we were at the interest aroused in our work, which had been carried on for years in almost unnoticed obscurity.

It is a comment on the human powers of deduction that while the tonic stimulus following exposure to sunshine, open air and sea-bathing, had been accepted instinctively, so little had been done to employ these natural therapeutic agents intensively and in the cure of disease, or enquire into the manner in which they could all be utilised systematically for treatment in appropriate cases.

Indeed I must confess that we physicians who were using sun treatment with success were to a large extent employing it empirically. We recognised that, carefully practised with suitable precautions, we had in our possession a wonderful aid to cure. We knew that certain effects could be constantly anticipated. We observed that the patients who tanned well generally did well; that the greater the area of skin that could be exposed the better for the patient; that the blood became richer in quality and anaemia disappeared; that the metabolic activity of our patients increased to a surprising extent and atrophied limbs swelled out and acquired muscular tone, associated rather with the athletic than the bedridden; that the mental condition of the patient improved, and the modern sun-worshipper was the happiest and brightest of mortals, in strange contrast to the peevish and irritable creature drawn from dingy urban hospital wards. Strangers perhaps, even more than we practitioners, drew attention to the robust health of the patients who, treated otherwise, were pallid, listless and apathetic, and marvelled accordingly. Visitors would constantly remark that they had anticipated that a visit to the Hospital at Alton would reveal sorrow and depression, but that nowhere had they seen healthier looking or happier children, abounding in animal spirits. On local lesions we soon discovered that no longer was it necessary to swathe wounds in costly dressings, but exposed to the sun they changed in character, became no longer foul and healed in spite of surgical aid, not because of it.

Gratifying as it was to note these phenomena and see returning health rapidly transform our patients, it was a corrective to conceit for one perceived that it was due to the employment of these free and natural aids to cure and not due to surgical skill or medical knowledge. Many other clinical efforts might be noted, but with these I need not detain you. But how were these results obtained? Only slowly was the question being answered, but recently a great addition has been made to our knowledge, chiefly by the labours of pure scientists, physiologists and others, amongst whom the names of two call for especial praise—Professor Leonard Hill and Dr. Sonne. One fact demands special notice. In the recent expansion of scientific knowledge, treatment of disease has been generally based on the researches and investigations of the laboratory worker. They discover principles and we clinicians then apply them in practice.

But in sun treatment, in sea-bathing and in the therapeutic use of open air, the reverse has taken place. Here I am glad to say clinicians have led. In the face of opposition, criticism, scepticism, or even worse, indifference, we have employed these aids to cure and the results have compelled attention and investigation. It has been especially interesting to me to note the changed attitude that has followed these investiga-

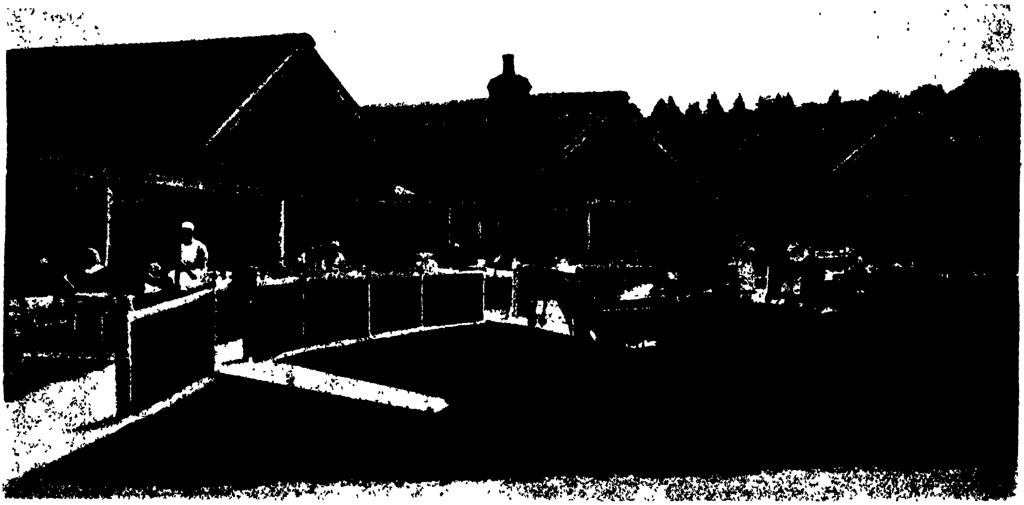

FIG. 1.—On the balconies at Alton. Sun and Shade Treatment.

tions, a change based on discoveries of profound importance, which discoveries will enable us to apply those methods of treatment with greater assurance and certainty, and make their application an exact science where formerly it was empirical practice.

In the short time which your kindly attention will permit I can perhaps best and most briefly describe the therapeutic action of sunlight under three headings: 1, Its psychological a tion on the mind; 2, Its direct or local effect; 3, Its indirect or remote action.

Of the first I will say little other than that sunlight has a powerful stimulating and tonic effect. It exhilarates and enlivens. It induces gaiety, liveliness and a sense of well being. It braces up and cheers the soul. Like all stimulants, if pressed to excess it intoxicates and then exhausts. Its action may not be unfairly likened to a draught of good champa ne.

Norman Davey well describes the effect of sunshine when he says:—

"The sun is a dispeller of ill-humours. He is the healer, the life giver. He is the only true doctor to the troubled mind. He is the best apothecary in the world. There is no tonic sold for gold over any chemist's counter so remedial as that celestial pick-me-up which is poured for nothing at daybreak, over that wide counter which is the rim of earth."

Not only is the vivacity of the patient increased, but his mental capacity is also raised and testimony to this is provided by the reports of teachers engaged in instructing children in "Schools in the Sun."

(2) The local or direct action. Sunlight has a powerful direct bactericidal action. It has been described as the world's great antiseptic. This property is especially strongly possessed by the ultra-violet rays in the sunlight. Unhap ily, the direct bactericidal action of light is strictly limited as the ultra-violet rays have very little penetrative power. They do not even traverse the human skin. The tubercle bacillus exposed to its direct action is speedily slain, but the penetrative power of the light is so limited that it is said that a similar bacillus. lying directly under the one exposed, would be protected and survive. When we consider how minute an object the tubercle bacillus is we can realise the limitations of light in this respect. Nevertheless it may be usefully employed for its direct action on local lesions. Unprotected organisms lying on the immediate surface of a wound will be slain, those more deeply situated are attacked by the beneficial inflammatory action which exposure to light, adequate in intensity and suitably timed and controlled, may provoke. In blanched anaemic tissues its penetrative action is increased and this fact is utilised in the Finsen light, where the lesion attacked is rendered anaemic, and an intense source of ultra-violet radiation is employed. In this way lupus, that disfiguring manifestation of cutaneous tuberculosis, may, if not too deep seated, be successfully treated.

(3) The indirect or remote action. The study of the remote effects of sunlight constitutes the most fascinating problem presented to the heliotherapeutist. Why and

how can deep-seated lesions protected by a mass of superjacent tissue which by no conceivable means can be reached by ultra-violet radiation, be favourably influenced ?

Let me give some examples of such conditions which may be favourably influenced and even cured by the action of the sun's rays, and here let me again state that these effects have been produced for years by means which we had not been able to explain.

(*a*) A patient had recurring attacks of severe stomatitis,—inflammation and ulceration of the mucous membrane lining the mouth. The condition proved very resistant to treatment and always recurred. Three exposures of the patient's back —not mouth please note—were given to a source of ultra-violet radiation. All the ulcers were soundly healed within one week, the stomatitis cured and the trouble has not recurred.

(*b*) A patient suffered from severe neuritis for years. No source of sepsis was discovered. No treatment was of any avail. Two exposures to ultra-violet light removed the pain and after five exposures the patient felt quite well and the condition has remained cured.

(*c*) A patient had symptoms of intestinal ulceration and later of obstruction. Laparotomy was performed and at the operation an intussusception was found which was reduced. In the abdomen was discovered a mass of mesenteric glands which it was deemed unwise to remove. After a course of sun-treatment during one summer the patient became completely well and remained cured.

(*d*) A patient suffered from multiple pyaemic abscesses of bone, and septic arthritis of the hip-joint. The casual organism was the staphylococcus. Numerous operations leaving sinuses had to be performed. One summer's sun cured all.

I could multiply such examples by hundreds, but need not weary you. But how can we explain these cures ? Recent research has thrown much light on the subject. For the explanation it is necessary for us to analyse the effects of the various wave-lengths of the solar spectrum. The solar spectrum consists of rays of varying wave-lengths, the infra-red, the luminous and the ultra-violet. The wave-length decreases in the order named and the penetrability likewise. The infra-reds especially heat the surface of the skin and produce severe superficial inflammation, even charring if exposure to a strong source is prolonged. Sonne has shown, by a series of very remarkable experiments, that the luminous rays have considerable penetrative power, are absorbed by and heat the blood-stream. Indeed their heating effect is so great that the blood may be locally raised to a very high temperature. By means of a thermopile inserted into a vein draining the irradiated surfaces he recorded temperatures of 115°F! Had the body generally been raised to such a temperature the effect would have been fatal but the body temperature is raised little above the normal, for the heated blood passing into the portal system is rapidly cooled. Remarkable also is the fact that though the blood beneath the irradiated skin is so hot, the temperature of the skin itself is only slightly raised. Now at such temperatures as this many bacterial toxins are said to be destroyed and the obvious step to take next was to see what effect was produced on such toxins injected into an animal. Accordingly lethal doses of diphtheria and typhoid toxin were injected into rabbits and guinea-pigs. Certain of these were irradiated with luminous rays from a carbon arc, others not irradiated remained as controls. Many of the irradiated animals survived, the controls died. It does not need a scientific mind to foresee what an enormous influence such a fact may have in its practical application in medicine.

Remarkable as were Sonne's observations I have others even more striking to announce. Only last month investigations were commenced by Professor Leonard Hill, Dr. Eidenow and Dr. Colebrook to ascertain if exposure to light rays had an effect on the power of blood to destroy micro-organisms. The haemobactericidal power of the rabbit is naturally very low. This animal was accordingly chosen and the organism selected for test was the staphylococcus, one of the most frequent of the micro-organisms infesting wounds. The blood of rabbits after exposure to sunlight, carbon arc, mercury vapour lamp and cadmium arc (the two latter especially rich in ultra-violet rays) was found then to have enormously increased bactericidal power. The further interesting observation was made that the bactericidal power of blood irradiated after being drawn was not increased, the increase only occurred after irradiation through the living tissues of the animal. The significance of these observations is very great. They, of course, need confirmation, but that will be certainly forthcoming. They need investigation in

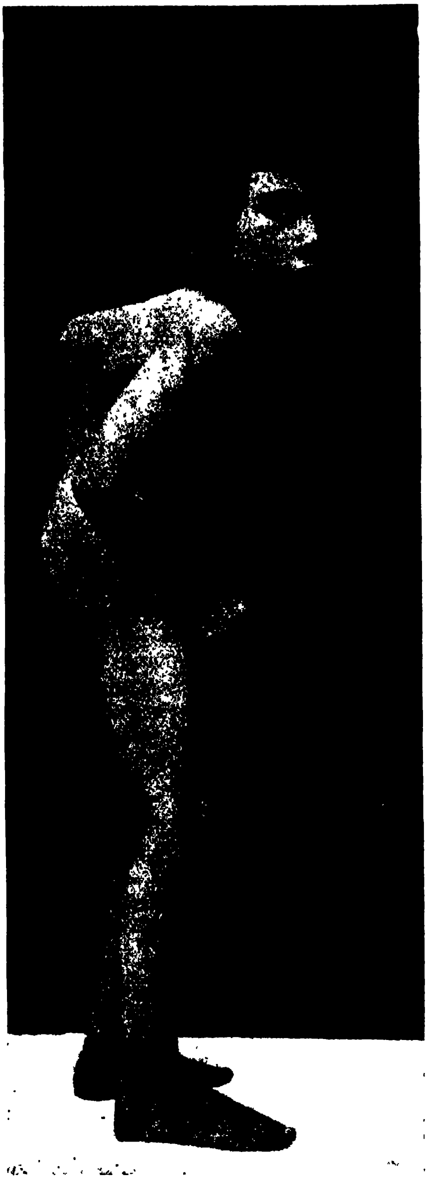

FIG. 2.—Tuberculous Disease of the Spine, before Treatment.

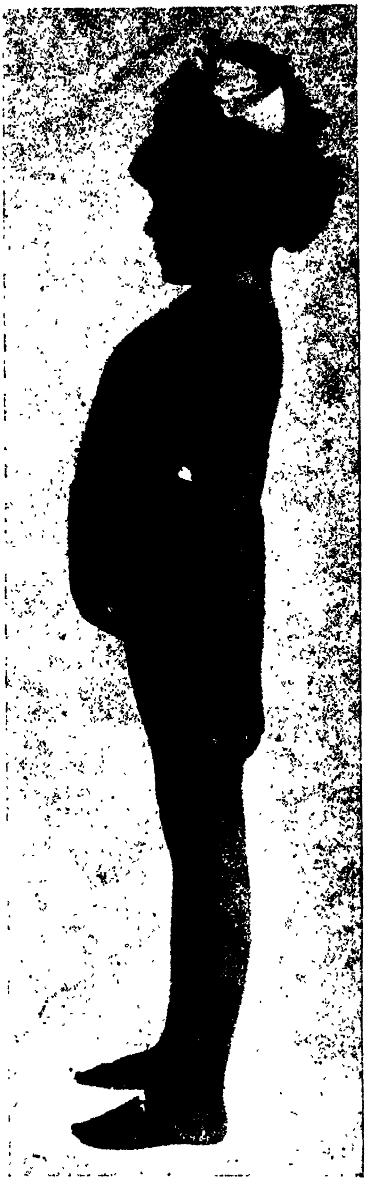

FIG. 3.—The same Patient with Disease arrested and Deformity corrected.

man but that also will be easy. But if confirmed in man, as I have little doubt they will be, a great and entrancing new chapter in therapeutics will have been opened. The manner in which sunlight acted on those cases I have described may probably be thus explained.

But confirmation of this property of ultra-violet light must be obtained and I would utter the warning that we must await patiently such confirmation which will certainly be speedily forthcoming or the fallacy, if one exists, exposed. The increased haemobactericidal power in rabbits remains for some two hours after exposure but may be repeated apparently indefinitely by further exposures.

Other functions of ultra-violet light I must not delay to describe: how it causes pigmentation of the skin and the prognostic, protective and other functions of that pigment: how it is a food sparer inasmuch as it will replace vitamines in a vitamine free diet and thus prevent or cure rickets; how it has an extraordinary analgesic power and can thus be utilised in the relief of pain (possibly this is but a result of its specific bactericidal power—future research can alone determine that).

There appears to be an antagonistic action of one series of waves of sunlight to others. Thus Professor Hill has shown that paramoecia exp. sed to a definite dose of ultra-voilet radiation are slain in a constant time. The addition of luminous rays markedly lengthens the lethal time and thus I suggest it is possible that harmful effects are guarded against in the varying wave-length of the solar spectrum. Pigment formed in our skins on exposure is also protective and thus longer exposures may be safely tolerated in the pigmented than in non-pigmented. During such polonged exposure the luminous rays continue their beneficent action, heating up the blood and thereby helping the ultra-violet rays to increase its bactericidal action.

In short, continued research but confirms Vignard's picturesque simile: "the skin becomes a vast keyboard on which the light strikes, awakening deep resonances throughout the body."

In the light of these recent investigations it becomes necessary and increasingly hopeful to modify technique in applying sun-treatment.

The value of the natural sun cure as at present practised is confirmed by weighty scientific evidence, but it may be enhanced and improved by logical utilisation of known facts experimentally obtained.

Professor Hill has devised an instrument by which the biological action of light may be accurately measured, and it now is possible to give definite known doses of ultra-violet light designed for particular purposes, instead of, as formerly, merely guessing from clinical observation and experience the amount of light which should be employed.

To the natural sunlight, which is likely to remain the best method of treatment for many cases, may be added particular radiations for especial purposes. Various wave-lengths may be utilised separately or in combination. Thus a very septic patient whose blood is swarming with pathogenic organisms and who is toxic to a dangerous degree may conceivably be first usefully irradiated with luminous rays to destroy dangerous toxins. Next he would receive ultra-violet light to increase his haemo-bactericidal power to slay living germs. Again, he would be irradiated with luminous rays to destroy the toxins liberated in the destruction of the pathogenic bacteria. Local superficial lesions might then be irradiated with infra-red rays to increase local inflammatory response and engorge these tissues with blood of high bactericidal power, and constantly natural sun baths over continous periods may be given to combine all effects and for their psychological value. Finally, as the patient can stand it, seabathing with the definite object of raising high his metabolic activity may be given, and other combinations of these natural therapeutic aids employed as individual requirements indicate.

On these lines the future light treatment at Alton will be conducted. There is obviously urgent need for extensive clinical research. By the generosity of Mr. Courtauld, to whom I would express my grateful thanks, a handsome donation of £1000 has been given to the Treloar Cripples' Hospital, earmarked for scientific research and apparatus, and the initial necessary apparatus is being purchased for the establishment of a great light department at Alton which I have long desired but have hitherto for financial reasons not been able to obtain.

I have occupied so much time in describing developments in light treatment, important and essential though they are, that my further remarks on open-air and sea-bathing in treatment must necessarily be very curtailed.

These subjects are themselves so important that the whole of the time at my disposal could have been profitably employed in their consideration alone.

Exposure to the sun has been known to be associated with increased metabolic activity in patients treated, and was formerly supposed to be the result of insolation. That may be partly true, but Professor Hill and Dr. Argyll Campbell after extensive investigations on our patients at Alton and Hayling Island, have demonstrated that this high metabolic activity, or increased capacity for work and tissue change, developed in these patients following sun-treatment, is due rather to exposure to cold air than to light. With insolation

FIG. 4.—After the Bathe. Patients are dried in the pens before the radiant heat of a fire, their feet are put in hot water, and they are given a hot drink. This is for the purpose of obtaining a brisk reaction. Patients then receive a sun-bath.

Such exposure to the air necessarily occurs, and increased metabolic activity was not unnaturally ascribed to the action of sunlight.

It was found that patients who pigmented well could tolerate exposures to sunlight for lengthier periods than non-pignenting patients, but the increase of metabolic activity was common to each class provided both were exposed equally to cold air. The progress made by good pigmenters was usually more rapid, and their average body weight higher than that of non-pigmenters, but increased metabolic activity was common to both, and was greater in winter than in summer. It is much higher in old patients acclimatised to the open air than in new. The further important observation was made that it remains high for a considerable period after exposure to open-air ceases. Thus the effect is a lasting one, and the benefits of such treatment remain for a considerable time after exposure has ceased. The effect of this high metabolic activity is to encourage tissue change. Greater oxygenation is effected. There is a greater ability of the patient to exercise his powers of response to stimuli. More body work is done, more food has therefore to be consumed and digested and generalised improvement becomes speedily manifest. It is important to note that there is an optimum metabolic activity, varying in individuals but which should not be exceeded. Excessive exposure to cold leading to shivering is not only unnecessary but actually cruel and harmful, and should always be avoided. It is, however, noteworthy that in well pigmented patients a considerable degree of cold can be borne not only without discomfort, but with very definite benefit. In very young patients, in the feeble and cachectic, and in the aged, great care must be exercised, and only very gradually should this treatment be attempted. In the vigorous, however, exposure to cold air is well tolerated, and when properly dosed not only causes no discomfort but is highly beneficial. The improvement in bodily tone and in general condition under specially graduated aerotherapy is remarkable especially when the long period of immobilisation in splints of those suffering from bone and joint disease is considered. The average basal metabolism of our immobilised patients is about 40 per cent. above that of the normal child. While exposure to cold air is gradually effective in securing an increased metabolic activity, paddling in the sea, spraying with sea water or total immersion affords us a means of very rapidly, accurately and, with due precautions, safely, obtaining similar results. Indeed metabolic activity during sea-bathing may, and often is,

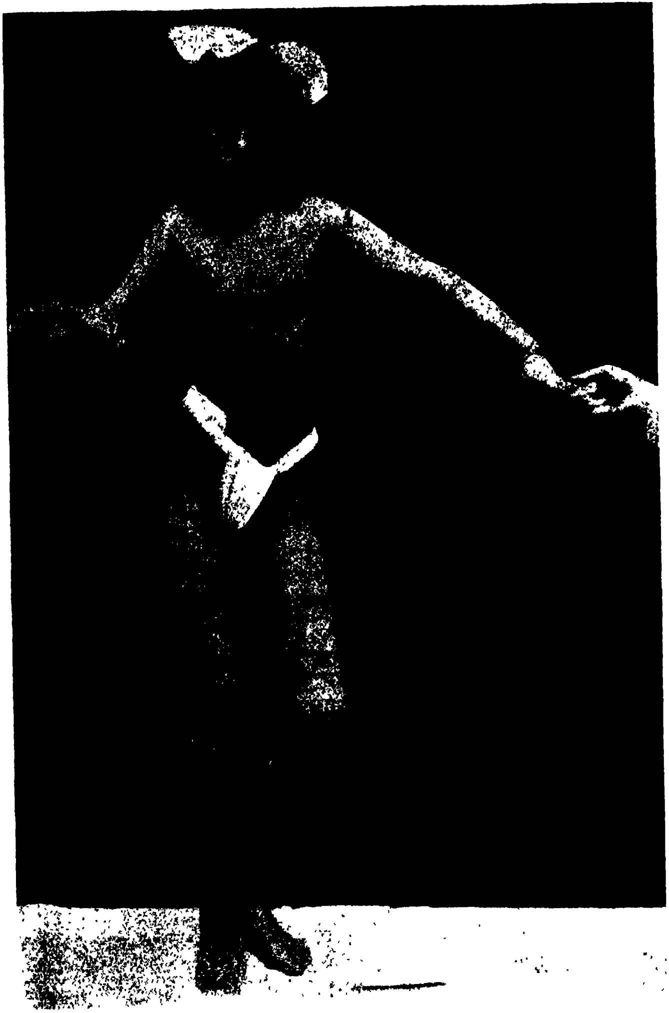

Fig. 5.—Tuberculous Disease of he Hip and Pubes.

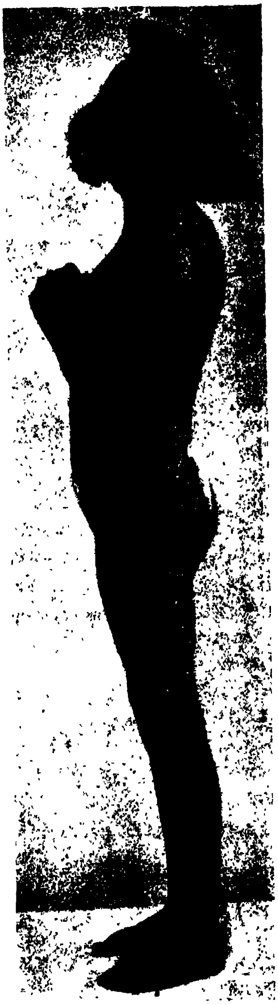

Fig. 6.—Same patient after Sun, Sea and Air Treatment. Note the excellent muscular development.

raised no less than 1000 per cent. above the normal. We thus have a very ready means of rapidly and intermittently increasing tissue change and stimulating heat production. This enhanced working capacity of the body is of great value to the patient suffering from surgical tuberculosis.

The stimulating effect of a sea bath in the open is much greater than of a bath in river water. Immersion is followed by deeper respirations which effectually expand the lungs and expel waste products. The circulation is profoundly modified. The first chilling effect causes contraction of the superficial capillaries, followed during the reaction stage by their dilatation. All parts of the body are, in phases, flushed by an increased volume of blood and lymph, which exercises its healing action on diseased bones and tissues. There is added excretion from the lungs and kidneys, and later from the skin, as well as absorption by the skin. Properly timed sea-bathing, followed by brisk towelling and a graduated sun bath, produces a sense of exhilaration and well-being which nothing else can convey. The amount of food consumed by the patients at Hayling Island during the bathing season is much greater than the proportion used at Alton, and is followed by marked muscular development and increase of tone.

On local lesions the effect is yet more striking. Discharging wounds secrete at first more; but the character of the discharge is changed, it becomes less purulent and more serous. The diseased tissues are flushed with lymph, which under the influence of the sun has acquired great bactericidal power. Later, the discharge diminishes, and in a large number of cases the sinuses dry up and leave supple and healthy scars. Fibrous tissue, which is fixing and rendering useless diseased joints, tends to become absorbed and movement regained. The improvement both general and local is, in suitably selected cases, rapid and striking.

Sun Treatment is more effective at the sea-side than inland. The mirror surface of the sea reflects the actinic and luminous rays but absorbs the heat rays. For some patients the stimulus at the seaside is too great, their powers of response are inadequate. This is especially true in the more toxic and younger cases. For these, inland treatment is to be preferred. But in the majority of cases alternation between inland and marine treatment provides the best and most speedy results, and the ability to obtain it greatly increases our powers for good.

CONCLUSIONS.

Bacteriological research, though of supreme and incontestable value, has had the effect of perhaps too much concentrating our attention on the cause of disease rather than on the patient attacked. We have assiduously studied the seed but neglected the soil. May I illustrate my meaning by simile ? There are plants of the mountains, the plains and the marshes. A mountain plant put in a marsh would soon die and *vice versa*. A potato would not flourish in a marsh, but drain the marsh and make the soil suitable and you may secure an abundant crop. The bacteria which attack us are but minute parasitic plants. To restrict or prevent their growth the soundest logic is so to change the nature of our bodies that they cannot successfully propagate or multiply. The methods of treatment I have described to-night are methods designed to this end. Doubtless, many other means will be discovered but here, at any rate, utilised wisely, exist means which nature freely places at our disposal and which need to be developed and widely used.

I have been at Alton now over 15 years. Colds and catarrhal conditions are almost unknown even in this bleak November weather. I cannot recollect one single patient having contracted broncho-pneumonia or even simple bronchitis. A change has been effected in their constitutions which prevents such conditions arising. I maintain the lesson to be learned is not to confine such advantages to our patients but make them generally available. Schools in the sun for weakly and healthy children should become general. Insolation during convalescence in isolation Hospitals would do much to prevent more serious infections which are notoriously deadly at a time when the danger of such infections is greatest, and little imagination is needed to suggest wide and general applications of the principles I have laid down. But while advocating this I feel it is my duty to warn those interested that these measures must be wisely and carefully introduced. Graduated exposures are essential and all needed precautions should be taken or methods of great hope and promise will inevitably fall into disrepute.

(At the conclusion of his paper Sir Henry Gauvain showed a long series of slides illustrating the treatment of patients at the Lord Mayor Treloar Cripples' Hospital.)

DISCUSSION.

MR. A. J. GREEN (L.C.C. Open-air Schools) said that, as he was only a schoolmaster, he felt rather doubtful whether he ought to make any remarks before such an audience containing several well known experts in this particular line. But he had this in his favour, that he was master of the first or almost the first open-air school in London He had been in this department of the London County Council service for fourteen years. Last year Sir Henry Gauvain came to Stowey House Open Air School, Clapham Common, and suggested the starting of a sun-cure class. Although the past summer, from the climatic point of view, was an appalling one, it was possible just to get the experiment in. The month of June and a part of July were available and even in that short time the results of this sun-cure class held on Clapham Common would amaze the audience. The class consisted of thirty-six youths from the slum areas of South London, such as the Borough and Bermondsey, the New Cut, and the Lower Marsh. They came into the garden of a private house on Clapham Common, and ran about in very short shorts and no shirts, and just socks and clogs. They were in the open all day long, and the result, thanks to Sir Henry Gauvain, was highly successful. The children became much more alert, their mental capacity certainly increased, as also did their appetites, and he looked forward next year, given a better summer, to an extension of the experiment with still more remarkable results. He was very proud to have been invited to Alton to see Sir Henry Gauvain's work at close quarters. It was a glorious work he carried on there. The children were amazing, and if anyone present had not seen them he should certainly make a point of doing so. He himself had been in open-air school work for fourteen years, and he thought his children were happy, but his children were a "wash-out" compared with Sir Henry Gauvain's. He had never seen anything which could approach the cheeriness and brightness of the children at Alton.

Dr. Rushton Parker said that he had been associated for twenty years with a sanatorium for consumption in the Lake District, and he could corroborate everything that Sir Henry Gauvain had said. One very severe winter—and winter was exceptionally severe in the Lake District—a stranger came at Christmas to look round the sanatorium and he made the remark that one problem at least which confronted the mother of a large family had been solved, for here were patients in a severe winter, each of them sleeping in an open air shelter under one blanket, and quite unable to tolerate two. The fact was that they were so thoroughly well fed that they were able to keep themselves warm by their own internal heat and could bid defiance to the climate. While he was in practice one of his horses got a very large abscess in the neck. He himself did not pretend to be able to extend his medical practice to animals, and so he put the horse under the care of a veterinary surgeon. After six weeks of cutting with knives and so on, there was no improvement, and so he took the animal away from the care of the "vet," hired a field, turned the horse into it, and did nothing else. In a very few weeks that horse got perfectly well. There was, however, one point that puzzled him. While he believed in open-air treatment and sunlight, how was it that fish got on so well at a depth of 2,000 fathoms, where they had no sunlight whatever? In the Natural History Museum there was a case-full of fish taken from that depth, and apparently they had been flourishing and had had very good appetites.

Dr. H. Chick said that she had been watching Sir Henry Gauvain's photographs with the liveliest admiration, and had also been greatly interested in the introductory part of his lecture. As one who had had a little experience of laboratory work on this subject, she felt that on the laboratory side they were still only on the threshold as yet, simply groping in the dusk. They hoped that the years would reveal something, but at present all was misty and dim. And sometimes the laboratory worker was inclined to envy people like Sir Henry Gauvain who could see the results before their eyes. She remembered in Vienna, when observing some young infants with rickets, being thrilled on more than one occasion by the sudden improvement shown in the monthly or weekly X-ray photographs of their bones following an exposure to the sun. It was the month of March, and as often happens at that time of the year in Vienna, the sun was streaming down although the air remained cold. Under such conditions the children were put out on the verandah, and within twelve days one of the infants showed a marked calcification of the rachitic bone as testified by the X-rays. This was accomplished without the slightest alteration in management or diet except that instead of being in a well-lighted and well-aired ward, the child was put out into the rays of the sun. Those were the sort of thrills that did not come quite in the same way to the laboratory worker. Her admiring congratulations were tendered to Sir Henry Gauvain for his wonderful results.

Mr. J. G. Thornton asked whether these methods of treatment were likely to be of advantage to the old as well as the young.

Miss Beadon said that she felt the more interest in what Sir Henry Gauvain was doing because in 1903 she and four other ladies set up a sort of sun-cure in Hampshire, quite close to Alton. The arrangements were very rough, but still some most wonderful things were achieved. The beginning of her interest in this matter was through being taught while at Nice, at a private international conference there, when she was quite a girl, the value of sunlight as a curative agent. The conference was held at the house of Mr. George Bishop, whose philanthropy had done so much for tuberculous patients and also for patients on the borderline. In 1900 she applied the same principles among some people in Wales, and in every single case the result was perfectly astounding. She herself was one of the last patients that Sir William Jenner saw, when she was only twenty-two. She was pronounced tuberculous, but she went out to the Isle of Wight and once or twice to Switzerland, taking the sun treatment, and she had never had a doctor since, except for slight accidents.

The Chairman (Lord Dawson) said that he was sure he was expressing the feeling of the entire audience when he thanked Sir Henry Gauvain for his most informing and encouraging lecture. His words must have brought to everyone present a feeling of gratitude and of hope. They would ask themselves earnestly how far these results would shape the treatment of the sick in future. One thing which this subject brought home to them was the need for a greater development of hospitals outside our cities instead of within them. With more hospital accommodation established in the country, it would be necessary to keep patients in the city hospital for a much shorter period than at present; cases which involved a long stay in hospital would be removed by a regular system of organisation further out. In the matter of education and preventive medicine, which were associated, the paper must also raise some very serious considerations. He called upon the meeting to accord a hearty vote of thanks to Sir Henry Gauvain.

The vote of thanks was passed unanimously.

Sir Henry Gauvain said that he was deeply grateful for the very kind reception that had been given to his remarks, and he thanked Lord Dawson especially for the great honour he had done him by coming there that evening. He felt very much indeed the value of his approbation in this work; it was an enormous encouragement to those engaged in heliotherapy. He thanked Dr. Chick for her more than kind remarks, and he wished to say how much he appreciated the wonderful work she had done in Vienna. She had opened up a new chapter in the treatment of rickets. One or two questions had been asked in the course of the discussion. Mr. Thornton had inquired whether these methods of treatment were applicable to older people. They were, but in the very aged, as in the very young, it was necessary to be careful, for they could not stand sudden exposure to extremes. Adult cases were, however, being treated by his friend Dr. Wood. He remembered the place Miss Beadon had mentioned, close to Alton, quite well, and she was entitled to special congratulation because her work synchronized with that of Dr. Rollier, at Leysin. The testimony of Mr. Green, a headmaster of long experience, as to the value of "schools in the sun" on the mentality of children, was valuable and encouraging.

The proceedings then terminated.

THE NEWCOMEN SOCIETY.

The Newcomen Society was founded in 1920 for the study of the history of Engineering and Technology. It is a subject which has certainly been much neglected in the past: while history has lavished her attention on the great soldiers and statesmen of the world, she has taken small notice of the engineers and inventors, whose labours have been mainly responsible for the world's advance in material well-being. The Newcomen Society aims at remedying this evil, and has amongst its objects the following:—(1) To disseminate historical information among its Members by meetings, intercourse, discussion, correspondence, circulation of notes and papers, and visits to objects and places of interest; (2) To act as a channel of communication between Members who are engaged on similar lines of research or study; to indicate as far as possible where information is to be found; (3) To collect and preserve or cause to be preserved, locally or nationally, examples, records, MSS., drawings and illustrations of or relating to engineering work and industrial processes; (4) To collect and preserve in a similar way biographical matter concerning those men who have contributed to engineering or industrial progress; (5) To print and issue to Members each year a volume containing original memoirs by Members, bibliographical notes and historical material not generally accessible; (6) To form by collaboration among its Members a card index of published information on the historical aspect of engineering and technology.

Two volumes of the Society's transactions have now been published, for 1920-21 and 1921-22, containing between them some fifteen papers, dealing with a great variety of subjects. Mr. Loughnan St. L. Pendred, now the President of the Society, contributes an interesting article, entitled "The Mystery of Trevithick's London Locomotives." It is remarkable that, in spite of the enormous influence exercised by Trevithick's work in the development of the steam engine, you may, as Mr. Pendred says, "search all the magazines, encyclopædias, and books on the steam engine issued during the first fifty years of the 19th century and find no more facts about Richard Trevithick and his work than would fill a column of *The Times*." Unfortunately much the same may be said about most of the world's great engineers and inventors, and this fact alone justifies the addition of one more to the already appallingly long list of learned and scientific societies.

Not the least interesting among the papers published in these volumes are those which deal with some of the earliest mechanical inventions. Thus, Mr. G. F. Zimmer, in "The Early History of Mechanical Handling Devices," shows a picture of an "Animated Bucket Elevator," taken from an alabaster slab in the British Museum, c. 700 B.C., while Sir George Greenhill, in the discussion following this paper, recalls a feat of Archimedes, c. 250 B.C., in hauling a laden ship over dry land. Mr. R. C. Skyring Walters gives an account of Greek and Roman engineering instruments, the excellence of which will surprise many engineers of to day, and help to explain some of the marvellous tunnelling feats mentioned in the paper. Mr. East Lones' account of "Mechanics and Engineering from the time of Aristotle to that of Archimedes" shows that engineering, like almost every other science and art, owed an enormous amount to the genius of the Greeks.

A word of praise must be added in recognition of the admirable manner in which the Transactions are printed and illustrated.

LA VIE INDUSTRIELLE EN FRANCE.

[The Council are of opinion that it would be useful to Fellows of the Society to publish a series of notes of important industrial developments in France. Through the kind offices of the Société d'Encouragement pour l'Industrie Nationale they

have been fortunate in securing the services o Monsieur Paul Calfas, Ingénieur des Arts et Manufactures, who will contribute such information from time to time.]

Les Turbo-Alternateurs de Grande Puissance de la Société Alsacienne de Constructions Mécaniques.

De même qu'en Angleterre et aux États-Unis, le besoin s'est fait sentir en France, d'employer, dans les stations centrales électriques, des groupes électrogènes de puissance unitaire très élevée. En même temps, on a augmenté la vitesse de ces groupes électrogènes, le plus souvent actionnés par des turbines, de façon à en augmenter le rendement et à en abaisser le prix.

Nous prendrons comme exemple de ces perfectionnements récents, d'après les renseignements donnés par M. Roth, ingénieur en chef de la Société Alsacienne de Constructions Mécaniques, les grands turbo-alternateurs à vapeur que construit cette Société dans ses usines de Belfort. Sa plus belle fabrication, jusqu'ici, est représentée par les groupes de 45.000 kva, tournant à 1500 tours par minute, qu'elle a installés en 1922 à la supercentrale de Gennevilliers, près Paris. Cette usine appartient à l'Union d'Electricité, et fournit le courant à toute la région parisienne.

Les problèmes à résoudre dans la construction de ces turbo-alternateurs sont à la fois d'ordre mécanique et d'ordre électrique. Le rotor cylindrique, massif ou lamellé, est encoché par fraisage ou par étampage, de façon que les dents font corps avec la masse du rotor. L'acier employé pour celle-ci, ainsi que pour l'arbre rotatif, est un acier au carbone supportant un effort de rupture de 50 à 55 kg. : mm2 avec une limite élastique de 35 à 40 kg. : mm2, et un allongement de 18 à 20%.

Pour le refroidissement des enroulements par ventilation, dans les très grands alternateurs, la Société Alsacienne emploie un système mixte consistant à faire passer l'air radialement dans les évidements du rotor, et à le faire circuler axialement dans le fond des encoches du stator, qui sont plus creuses que ne le comportent les enroulements. L'air échauffé est ensuite refroidi par de l'eau, par exemple l'eau sortant du condenseur.

La protection des enroulements contre les effets des courts-circuits est souvent obtenue au moyen de bobines de réactance extérieures à la machine ; mais, dans les grands alternateurs modernes, on supprime ces bobines et on donne à la machine une grande réaction d'induit, ou bien on augmente artificiellement les fuites ; en outre, on consolide fortement les têtes de bobines : la Société Alsacienne emploie concurremment ces divers procédés.

La Construction Automobile Française et la Salon de l'Automobile de Paris.

(Octobre-Novembre 1923.)

La construction automobile française s'est de nouveau brillamment affirmée au dernier Salon de l'Automobile. L'année 1923 aura vu mettre en service plus de 120,000 voitures neuves, et la petite automobile populaire fait rapidement son chemin. Nos plus grandes firmes : Citroën, Renault, Peugeot, Voisin, etc., lancent dans le public des voiturettes de 5 à 8 chevaux, assez bon marché (10,000 à 12,000 francs), très bien construites, commodes, légères, et de conduite facile, grâce au démarrage électrique.

D'autre part, la voiture de luxe et de forte puissance continue à être fabriquée pour une large clientèle d'élite, par des constructeurs de haute réputation, tels que Panhard-Levassor, Lorraine-Dietrich, de Dion-Bouton, Delahaye, Delage, et bien d'autres encore.

Le Salon a permis de constater que les moteurs fonctionnent actuellement avec de plus grandes vitesses et de plus hauts rapports de compression. Pour cela, il a fallu placer les soupapes dans une culasse démontable, alléger les pièces mobiles et surtout les pistons, par l'emploi d'alliages d'aluminium, perfectionner l'équilibrage des masses en mouvement, améliorer le réglage des distributions, etc.

La grande majorité des moteurs sont à 4 cylindres, et quelques-uns à 6 cylindres ; les autres nombres sont à peine employés. Un quart des moteurs ont de 1½ à 2 litres de cylindrée totale, et un autre quart ont de 2 à 3 litres ; un petit nombre seulement ont plus que 3 litres de cylindrée. Les quatre vitesses sont également de règle sur les trois quarts des châssis ; les voiturettes n'ont que trois vitesses.

La formule du bloc-moteur est généralement adoptée ; très souvent, le bloc est fixé en trois points et porte les pédales, ainsi que les leviers, pour laisser au châssis toute facilité pour se déformer.

Le freinage sur les quatre roues se développe rapidement, et s'imposera bientôt sur toutes les voitures de 10 chevaux et davantage, en raison des vitesses élevées qui sont usuelles aujourd'hui. Pour les châssis lourds, les forces du conducteur étant limitées, on les combine avec des servo-freins. Signalons aussi, parmi les éléments de confort que réclament aujourd'hui les automobilistes, un gonfleur de pneumatiques actionné par le moteur.

Le Ciment Fondu.

Le ciment fondu est considéré comme devant apporter des modifications importantes aux constructions civiles et aux travaux publics. En France, où il a été fabriqué industriellement pour la première fois, il a reçu, depuis peu, d'intéressantes applications. Le ciment fondu est un produit obtenu au four à cuve ou au four électrique, et dont la composition moyenne est la suivante :

SiO_2, 10 à 12% ; Al_2O_3, 40 à 45% ; CaO, 35 à 40% ; Fe_2O_3, 10 à 15%. Son indice d'hydraulicité est supérieur à 1,25.

Les principales propriétés du ciment fondu sont la rapidité de la prise et la grande résistance du béton quelques heures après le gâchage. On peut

décintrer un ouvrage en béton de ciment fondu le lendemain de la mise en place du béton. La résistance au bout de 24 heures est de 29 kgs. par centimètre carré à la traction, et de 352 kgs. à la compression. Cette résistance étant bien supérieure à celle du béton ordinaire, on peut établir les structures plus légères, et par suite donner une plus grande portée aux ouvrages. On envisage la construction de voûtes de plusieurs centaines de mètres d'ouverture.

On a proposé également l'emploi de ce ciment pour construire des ponts en béton armé de la même manière que des ponts métalliques. On moulerait à l'avance des éléments de treillis, et on les réunirait par des joints en ciment fondu, faisant prise en quelques heures. La construction pourrait ainsi être très rapide.

Dès maintenant le ciment fondu a reçu diverses applications intéressantes. On l'a employé pour construire le plancher tronconique du théâtre de Lyon. On utilisait un coffrage radial sur lequel on moulait un secteur étroit de la construction, et qu'on déplaçait presque aussitôt pour mouler le secteur voisin, et ainsi de suite. On a fait ainsi l'économie d'un coffrage complet.

Les travaux de réfection du pavage en bois de Paris, l'été dernier, ont été accélérés par l'emploi du ciment fondu. On établissait la forme un jour, et l'on pouvait poser les pavés dès le lendemain matin.

Une excellente expérience du ciment fondu a été obtenue pendant la guerre, où il a été employé pour construire des plateformes d'artillerie. Avec le ciment Portland, il aurait fallu 6 semaines de prise, et avec le ciment fondu 3 jours suffisaient. On a pu avec ce produit construire des abris de mitrailleuses blindés jusqu'en première ligne.

Un pont en béton armé construit à Lausanne (Suisse) a pu recevoir des tracteurs de 12 tonnes 48 heures après la coulée du tablier en béton de ciment fondu.

Le ciment fondu est fabriqué maintenant d'une façon courante, et son emploi est prévu pour divers travaux importants.

NOTES ON BOOKS.

THROUGH FORMOSA: AN ACCOUNT OF JAPAN'S ISLAND COLONY. By Owen Rutter. London: T. Fisher Unwin, Ltd. 15*s.* net.

Formosa is well off the beaten track of tourists, and apparently little encouragement is given by the Japanese Government to visit the island; but by a stroke of good luck Major and Mrs. Rutter were enabled to see the country under the most favourable auspices, and as a result we have this book which gives an account of its history, its natural resources, and its native people. It also shows "how in thirty years the Japanese have succeeded, marvellously succeeded, in developing economically what was, when they first took possession of it, little more than a wilderness; and . . . how they have failed, for all their good intentions, in their attempt to settle and administer the native tribes, made intractable by centuries of tyranny and oppression."

Major Rutter modestly states in his preface that his work makes no profession of being a standard work on Formosa: it is written by a passer-by, "who does not profess to have an intimate and exhaustive knowledge of the country such as can be attained only after many years' residence." He has, however, spent a long time in the Far East, and as readers of the *Journal* will know from the admirable paper on "British North Borneo," which he read before the Society last December, and from his book on the same subject which was noticed in these columns about a year ago, he is a keen observer with a wide experience of administration among the Bornean tribes. He was able, therefore, to collect as much information in a short trip as an untrained visitor would amass in many months.

The Japanese, Major Rutter assures us, have met with extraordinary success in every commercial, industrial, economic and scientific enterprise they have undertaken in Formosa. Take the sugar industry, for example. The land under sugar-cane cultivation is now about 300,000 acres, while the annual export of sugar is 250,000 tons, or ten times the amount exported when the Japanese took over the island. Camphor, again (one of the most important products of Formosa) has been greatly improved in quality, and the monopoly in it brings in to the Government no less than £800,000 per annum. Salt, opium, tobacco and alcoholic liquors are also flourishing industries; and some idea of what Formosa trade has gained under Japanese rule may be gathered from the fact that the total of the island's imports and exports has risen steadily from £3,124,696 in 1897 to £27,695,929 in 1922.

But if Japan has succeeded on this side of her work she has failed lamentably in the question of the settlement of the native population. Seven thousand square miles of Formosa, exceedingly rich in camphor forests and probably also in minerals, still remain inaccessible to her. The Japanese are defied by 100,000 pagans, "and inside the electrified barbed-wire entanglement with which they have surrounded these children of the forest they can only venture with their lives in their hands." Major Rutter believes that this failure is due to lack of sympathy and of experience. Before they came to Formosa the Japanese had done no colonising; they still look upon the "savages" as a nuisance and an obstacle, and they have no idea of making friends with them. From certain characteristics which the natives of Formosa share with those of Borneo, Major Rutter believes that the methods which have civilised the British colony would be not less successful with the Japanese.

Journal of the Royal Society of Arts.

No. 3,710. VOL. LXXII.

FRIDAY, DECEMBER 28, 1923.

22 JAN 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2).

NOTICES.

NEXT WEEK.

Wednesday, January 2nd, at 3 p.m. (Mann Juvenile Lecture.) Dr. William Arthur Bone, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology, "Fire and Explosions." (Lecture I.) The lecture will be fully illustrated with experiments.

Special tickets are required for this course and for the Mann Juvenile Lecture by Mrs. Julia W. Henshaw, F.R.G.S., Croix de Guerre, entitled "Among the Selkirk Mountains of Canada (with ice-axe and camera)," to be delivered on Wednesday, January 16th, at 3 p.m. A few tickets for both courses are still left, and these will be issued to Fellows who apply for them at once.

COMPETITION OF INDUSTRIAL DESIGNS.

Particulars of the Competition of Industrial Designs to be held at the Victoria and Albert Museum in June, 1924, can now be obtained on application to the Secretary, Royal Society of Arts. Over £1,000 will be offered in Travelling Scholarships and Money Prizes in the various sections, and the Society's Diploma will be conferred on any candidate whose work reaches a very high standard of artistic ability and shows practical knowledge of the materials and processes of his trade.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

Wednesday, December 5th, 1923.

Professor C. A. Seward, Sc.D., F.R.S., Pres.G.S., F.L.S., Professor of Botany in the University of Cambridge, in the Chair.

The Chairman said that it was his great privilege to introduce to the Society the Director of Kew, who would speak about the many activities of the Royal Gardens. Dr. Hill had not presided for many years over the destinies of Kew as Director, but he had been associated with the Gardens for a long time past in another capacity. Before he went to Kew he was at Cambridge, and there the speaker had had the opportunity of being with him in the same Departments of that University. He left a School mostly concerned with pure science for an institution which was concerned with both pure and applied science—with pure science to the greater degree, although, of course, it was difficult to draw the line between the two. He had pleasure in calling upon Dr. Hill to read his paper.

The paper read was:—

THE WORK OF THE ROYAL BOTANIC GARDENS, KEW.

By Arthur William Hill, M.A., Sc.D., F.R.S., F.L.S.,

Director, Royal Botanic Gardens, Kew.

Before attempting to give you some account of the work of the Royal Botanic Gardens, Kew, I feel it is essential to a proper understanding of the functions of Kew to consider for a few minutes the early history of the Gardens, how they came into being, and how their development as the Headquarters of Botanical Enterprise for the British Empire gradually materialised.

As with so many of our National Institutions, Kew, as we know it to-day, was not evolved in any deliberate manner, or as the result of some carefully conceived plan in the brain of any far-seeing Empire builder. Its origin was due to the interest in horticulture of that eminent lady, Princess Augusta of Saxe-Gotha, widow of Frederick, Prince of Wales, who in 1760, under the guidance of the Earl of Bute, started a Botanic Garden of some nine acres in the vicinity of Kew House. Frederick himself would appear to have been interested in gardening pursuits, for after his acquisition of Kew House on a long lease from the Capel family in 1730, he commenced a fresh arrangement of the pleasure grounds, and made additional plantations under the direction of the celebrated Kent.

It was after Frederick's death in 1751 that Princess Augusta gave to Kew Gardens the definitely scientific character they have ever since maintained.

The date 1760 may be accepted as the commencement of the Botanic Garden, as it was towards the close of the year 1759 that William Aiton, who had been a pupil of the famous Philip Miller at the Chelsea Physic Garden, was engaged by the Dowager Princess of Wales to establish at Kew a Botanic, or, as it was then termed, a Physic garden.

Princess Augusta died in 1772, but during the last twelve years of her life she was assisted in her botanical pursuits by John Stuart, third Earl of Bute, who was keenly interested in botany. This science, apart from his brief political career, was the principal occupation of his life, and his interest in botany has scarcely received the appreciation it deserved. It should, however, be borne in grateful remembrance that he took a very active part in developing the botanical side of Kew. Some of the trees planted under his direction still exist, notably the fine Maidenhair tree (*Ginkgo*) and a *Diospyros* near the site of the Temple of the Sun, which among others were probably brought from the garden of the Duke of Argyle near Hounslow in 1762.

That the collection of plants at Kew in these early days was a remarkable one is shown by Sir John Hill's *Hortus Kewensis*, published in the year 1758, which was an octavo volume of 458 pages forming a catalogue of the plants cultivated in the garden of Her Royal Highness the Dowager Princess of Wales at Kew. This catalogue enumerates 3,400 species, 488 being hardy trees and shrubs and 200 tender shrubby plants; while in 1770 Sir John speaks of Kew as "that garden where every tree that has been seen in Europe is at hand."

After the death of Princess Augusta, George III. purchased the freehold of Kew House and grounds from the Dowager Countess of Essex, and amalgamated them with the gardens of Richmond Palace, which had been the residence of George II. and Queen Caroline. Love Lane, which separated the two properties, was the old roadway from Richmond to Brentford Ferry, and the present Kew Road is its successor. The original Love Lane is still preserved in the Holly Walk in the Gardens, but though George III. was empowered to close the lane in 1765, it seems doubtful whether the two Royal Gardens were really united until about the year 1802. Many of the trees still at Kew, in the part which was formerly Richmond Gardens, were planted under the direction of Queen Caroline.

With the acquisition by George III. of the two Royal Gardens and the appointment of Sir Joseph Banks as Botanical Adviser, or in effect "Director" of the Royal Gardens, in place of Lord Bute, the "Golden Age" of Kew may well be said to have commenced.

The King maintained the botanical character of Kew with even greater energy than did his Mother, and supported with keen interest the various botanical activities initiated by Sir Joseph Banks, which have resulted in Kew occupying the position it holds to-day in relation to botanical enterprise throughout the Empire.

To Sir Joseph was due that practice, which has yielded such fruitful results, of sending out collectors to various parts of the British Empire and to other countries, which, after lapsing and being revived by Sir William Hooker, has in recent times been continued by the leading nurserymen and by private enterprise.

In the year 1772, Sir Joseph Banks, being then President of the Royal Society, addressed a memorandum to the King with reference to sending Francis Masson, an under-gardener at Kew, to collect seeds and living plants at the Cape of Good Hope "for the Royal Botanical Garden at Kew."

Masson made remarkably fine collections, and sent home over 400 species of living plants. At least one of his plants, the interesting Cycad *Encephalartos longifolius*, still exists in the Palm House, while among others were *Cineraria cruenta*, the parent of our garden Cinerarias, and the wild Cape Pelargoniums, from which have been evolved our garden "Geraniums." From the long list of Kew Collectors one or two names deserve special mention. Among them, that of David Nelson, who was Assistant Botanist on Captain Cook's third voyage, and subsequently accompanied Captain Bligh on the ill-fated voyage of the "Bounty." The genus *Eucalyptus* was founded by L'Heritier—the French Botanist who came to England 1786-87, and studied the Kew collections—on a species (*E.obliqua*), which was found by Nelson in Tasmania. Then there is Archibald Menzies, who accompanied Captain Vancouver (1791-95), and brought home seeds of the Chilian Monkey Puzzle (*Araucaria imbricata*), which Sir Joseph

Banks planted, some at his own place at Spring Grove, Isleworth, and the others at Kew. It is a pity that Sir Joseph's name is not still commemorated by the retention of the early name "Sir Joseph Banks' Pine," by which it was first known. Menzies also discovered *Sequoia sempervirens*, the Californian Red Wood. I must also refer to Christopher Smith, who went with Bligh on his second successful voyage to convey the Bread fruit to the West Indies, and afterwards collected in India; Peter Good, who was in Calcutta and Australia; George Caley, who was appointed by Sir Joseph as botanical collector in New South Wales; William Ker, who was sent to collect in China; Alan Cunningham, who travelled as a collector for Kew, in Brazil, The Cape and Australia, and David Lockhart, who was the only survivor of the scientific staff of Captain Tuckey's Congo Expedition of 1816. These are some of the most famous of the earliest of the Kew Collectors.

Three of these same men also deserve further mention, namely, William Ker, who in 1812 was appointed Superintendent of the Royal Botanic Garden, Ceylon, founded in 1810; George Caley, who was Superintendent of the Botanic Garden, St. Vincent, from 1816 to 1822—the earliest of our Tropical Gardens founded in 1765—and David Lockhart, who was apparently the first Superintendent of the Botanic Garden in Trinidad, where a Garden was founded in 1817. Thus began that long and valuable connection, which still happily exists, between the Royal Botanic Gardens, Kew, and the daughter Botanic Gardens which have gradually been established in practically every British Colony and Dominion.

A glance at the *Kew Bulletin* appendices giving the List of Staffs of the Botanical Departments at home, in India and the Colonies during the last 35 years, will show that gardeners trained at Kew are at the present time, or have been until quite recently, in places so remote as the Falkland Islands, the Fiji Islands, the Seychelles, Rodriguez, Central Africa, Hong Kong, Port Darwin, Australia, New Zealand, and, in fact, throughout the British Empire.

One of Sir Joseph Banks' schemes was to found a Herbarium and Library at Kew. The present Herbarium and Library occupies the house originally known as Hunter House (the property of Mr. Robert Hunter), which it is believed was purchased for the King in 1818, at the instigation of Sir Joseph Banks, for the purpose to which it is now dedicated. A room on the ground floor was fitted with bookshelves, and no doubt the botanical collections brought home by the Kew Collectors were deposited in the building.

Unfortunately, the King and Sir Joseph both died in 1820, and Kew suffered greatly in consequence. Sir Joseph's Library and Herbarium, including the botanical specimens brought home by the Kew Collectors, were bequeathed to the British Museum, and became the foundation of its Botanical Department, so that Kew, unfortunately, does not now possess the fruits of the labours of her earliest sons.

George IV. at first took a good deal of interest in Kew, and adhered to the plan of adapting Hunter House to its present purpose. He also added considerably to the amenities of the Gardens on the Kew Green side, but in 1823 he sold Hunter House to the Nation. Notwithstanding this, however, William IV., about 1830, granted its use to the Duchess of Cumberland for her life, and, on the Duke's accession to the throne of Hanover, it became generally known as Hanover House. Here the King of Hanover sometimes resided, but after his death in 1851, it remained unoccupied, and in 1852 its use for Herbarium purposes once more commenced, thanks to the action of Sir William Hooker.

The house itself now serves as our Library, while the Herbarium occupies two extensive wings which have been added to the north and to the west of the original house. The Herbarium contains a remarkable series of specimens of dried plants from every part of the world, representing especially the floras of the various parts of the British Empire. Between 3,000,000 and 4,000,000 specimens and comprehensive collections of plant portraits, fruits and seeds, are preserved in the Herbarium, while the Library, which is probably the finest botanical library in existence, contains some 30,000 volumes. The annual additions of pressed specimens to the Herbarium amount to about 30,000 sheets.

The death of Sir Joseph Banks, in 1820, was a serious blow to Kew, and though the activities which he initiated, and which received such warm support from George III., were continued to some extent after his death, there was no real progress in the development of the Gardens, but rather they suffered a steady decline.

George IV. soon abandoned Kew for Windsor and Sir Everard Home appears to have assumed the task of directing the affairs of Kew, and used to meet at the house of Francis Bauer "the eminent men of the day for purposes connected with Botany and other branches of Natural Philosophy."

Francis Bauer, F.R.S., it should be mentioned, was an Austrian who came to England in 1788 and in 1790 was, through Sir Joseph Banks' liberality and with the King's sanction, attached as Draughtsman to the Botanic Garden. He occupied the position for fifty years, until his death in 1840. This most essential post in connection with a Botanical Institution such as Kew has recently been properly recognised by Government, and a Botanical Artist is now one of the established officers on the scientific staff of the Royal Botanic Gardens.

Sir Everard Home died in 1832, two years after the death of George IV., and, though William IV. took a warm interest in Kew, the Gardens and all that Sir Joseph Banks had laboured to achieve, languished, and their scientific importance was so lost sight of that the scientific botanists of the day appear almost entirely to have got out of touch with Kew.

Collecting activities fortunately did not entirely cease, and some valuable additions were made, but the Gardens were still a private establishment. Visitors, however, had free access on certain days, thanks largely to Mr. W. T. Aiton (son of the first Curator, W. Aiton), who was Director-General not only of Kew but of other Royal Pleasure Gardens in addition.

It was after the death of William IV., in 1837, that the position of the Royal Gardens became precarious, and their abandonment was seriously considered, so much so, that the Treasury in January, 1838, appointed a Committee "to inquire into the management, etc., of the Royal Gardens." This committee consisted of Dr. Lindley and two practical gardeners, one of whom was the future Sir Joseph Paxton. Without going into the full details of their inquiry, and narrating all that took place when Dr. Lindley's Report was presented to Parliament in 1840—though he reported in 1838—it will suffice to record that after the discussion in the House of Lords, the charge of Kew was removed from the control of the Board of Green Cloth, and transferred to the Department of Woods and Works on March 11th, 1840.*

On the dissociation of the Department of Woods from the Office of Works, Kew, like the Royal Botanic Gardens, Edinburgh, came under the control of H.M. Office of Works, but though the Edinburgh Gardens are still in the domain of the First Commissioner of H.M. Works, Kew was transferred in 1903 to the care of the Board (now the Ministry) of Agriculture and Fisheries, as far as its general administration is concerned.

When this transfer took place, it was laid down "that the privilege enjoyed by the Foreign Office, Colonial Office and India Office of corresponding directly with the Director will be preserved to those Departments," and I need hardly point out, that from the nature of the work performed at Kew, this very important privilege is highly valued by the Director of Kew.

The outcome of Dr. Lindley's Report was the renaissance of the Royal Gardens, which dates from the year 1841, when, on April 1st, Sir William Hooker, F.R.S., Regius Professor of Botany in the University of Glasgow, was appointed Director of the Botanic Gardens.

In the year 1841, W. T. Aiton resigned his position of Superintendent of the Botanic Garden—a post he had held for fifty years—and John Smith, previously Foreman, was appointed Curator, and was the first Curator of Kew as a Public Establishment.

The continuance of the existence of Kew in these evil days seems to have been due rather to the interest of Her Majesty Queen Victoria, than to the popular agitation that its proposed abandonment aroused. The following extract from a letter to John Smith by Mr. Aylmer Bourke Lambert, a private gentleman keenly interested in botany, who seems to have succeeded to the role of Sir Joseph Banks in the affairs of Kew, is of interest in showing the part played by the Sovereign in the preservation of Kew.

---

*The following is the principal part of Dr. Lindley's Report presented to Parliament in 1840.

"The importance of Botanic Gardens has for centuries been recognised by the governments of civilised states, and at this time there is no European nation without such an establishment except England. The wealthiest and most civilised country in Europe offers the only European example of the want of one of the first proofs of wealth and civilisation. There are many gardens in the British Colonies and Dependencies, as Calcutta, Bombay, Saharunpore, the Mauritius, Sydney and Trinidad, costing many thousands a year; their utility is much diminished by the want of some system under which they can all be regulated and controlled. There is no unity of purpose among them; their objects are unsettled, their powers wasted from not receiving a proper direction; they afford no aid to each other, and, it is to be feared, but little to the countries where they are established; and yet they are capable of conferring very important benefits on commerce, and of conducing essentially to colonial prosperity. . . . A National Botanic Garden would be the centre around which all these lesser establishments should be arranged; they should all be placed under the control of the chief of that garden, acting with him and through him with each other, recording constantly their proceedings, explaining their wants, receiving supplies, and aiding the mother country in everything useful in the vegetable kingdom; medicine, commerce, agriculture, horticulture, and many branches of manufacture would derive considerable advantage from the establishment of such a system. . . . From a garden of this kind Government could always obtain authentic and official information upon points connected with the establishment of new colonies."

March 9th, 1840. "You will not be a little surprised, and I think not less grateful when I tell you that your letter that you wrote me giving particulars of the origin of Kew Gardens, and the interest taken by the Princess of Saxe-Gotha, that said letter went to the throne, and (was) read by Her Majesty and Prince Albert, they were much interested in it. There is no doubt that was the reason Lord Ilchester came to Kew, as he is one of Her Majesty's household."

Sir William's charge, when he assumed office, comprised only 15 acres, yet his appointment inaugurated that new era in the history of Kew, which, though perhaps in some directions not so eventful as in the days of Sir Joseph Banks, has been a period of uninterrupted progress and notable achievement.

These, then, were the traditions of Kew, and such were the labours of other men into which Sir William Hooker, in 1841, was called upon to enter. In that year, Kew was not, alas, the inspiring place created by Sir Joseph Banks, but a moribund and decadent institution waiting to be restored to its former eminence, a task for which Sir William was peculiarly fitted. It is no doubt his son and successor in office, Sir Joseph Hooker, who is generally thought of as the Director who re-established the prestige of Kew and succeeded in making it the centre of botanical enterprise for the Empire, but it must not be forgotten that practically every one of the proposals and schemes for the development of the work of Kew on the lines which are still followed, were conceived with remarkable foresight and set in motion by Sir William Hooker.

In 1843 Sir William Hooker, as I have stated, reverted to the plan initiated by Sir Joseph Banks, of sending collectors to distant countries for the purpose of transmitting plants and seeds to the Royal Gardens. Among Sir William's Collectors should be mentioned W. Purdie, who was sent to New Granada; G. Mann, who went to the Cameroons, Gaboon River and Fernando Po; W. B. Baikie and C. Barter, who went to the Niger; John (later Sir John) Kirk, to the Zambesi with Livingstone; Sir Joseph Hooker to the Himalaya; Edmonstone, followed by B. C. Seemann, to Western and Arctic America in H.M.S. Herald, and the latter to the Fiji Islands with Col. Smythe's mission, and also R. Spruce who was sent to Ecuador for Cinchona seeds.

It would be a long story were I to attempt to give in detail the history of the many activities of Kew, even with regard to India and our overseas Dominions and Colonies during the Directorships of the two Hookers, of Sir William Thiselton-Dyer and of Sir David Prain; for the Director of Kew is also Botanical Adviser to the Secretary of State for the Colonies, and is consulted on Indian botanical matters by the Secretary of State for India. Thus the shelves of the Director's office are filled with folios dealing with questions concerning the introduction of useful plants to our Colonies and India from other regions, and with every sort of enquiry as to the world's economic products so far as they relate to the vegetable kingdom.

The work of the Royal Botanic Gardens, Kew, is divided up into four main divisions, only one of which, however, is generally known about and appreciated by the people of this country. This, I need hardly say, is the garden proper. To most people the name Kew Gardens, or as they should properly be called, the Royal Botanic Gardens, Kew, represents a beautiful garden of herbaceous plants, trees and shrubs, and many greenhouses, some of which they find uncomfortably hot. To a select few, who, one is glad to say, are ever an increasing number, the Gardens are recognised as the place where the attempt is made to cultivate every variety of plant "that is pleasant to the sight and good for food," under the best conditions that Kew can provide, and they, together with those botanists who are also lovers of plants, fully appreciate the scientific order of the collections. These have been so skilfully arranged, thanks largely to the keen instinct for landscape effect possessed by Sir William Thiselton-Dyer and by the Curators of the Gardens, that the general public are scarcely aware that the garden lay out is governed by any scientific principles at all.

One is tempted to believe that among our many student visitors there are some who have realised that the "Tree of Knowledge" also is to be found at Kew.

The next department which commands a fair share of public interest, and also, one hopes, serves as a means of liberal education, is that of the Museums.

Four Museum buildings now house the varied and extensive economic collections, which comprise examples of the economic products of the plants of the world. The Museum collections, though brought together with the definite purpose of illustrating the uses to which plants may be put, are really complementary and ancillary to the collections in the Herbarium and in the Garden, and one collection without the other would lose very much of its importance and value. The housing of the collections in four separate buildings, is an unfortunate arrangement as far as economical working of the Department is concerned, and also somewhat unsatisfactory since three of the buildings have been adapted to serve their present purpose and are not as well suited for the exhibition of specimens as they might be.

The original museum collection, which was the first of its kind brought together for the purpose of exhibiting in systematic order the economic products derived from plants, was due to the foresight of Sir William Hooker. In 1847, owing to Sir William's representations, the fruit storehouse belonging to the Royal Family, now Museum No. II., was, by Her Majesty's command, added to the Botanic Garden and Sir William's own private collection, which he presented to the Nation, formed the nucleus around which our present extensive collections have been built up.

The objects exhibited could not be shown either by the living plants in the Garden or by the specimens preserved in the Herbarium, and the value of these collections has become increasingly evident in the course of years; so that now practically every vegetable product from any part of the globe can be accurately determined.

As soon as the establishment and aim of the Museum was generally made known, contributions poured in from all quarters of the world, and the original building became so crowded that application had to be made to Parliament for a new building for the proper accommodation of the specimens.

In 1857, to meet this need, the present No. 1 Museum was opened. Here the economic products derived from the Dicotyledonous plants (including such well-known objects as cocoa, coffee, cinchona, rubber, tea, etc.), are displayed, while the products derived from the Monocotyledons, such as palms, bamboos, grasses, the various food grains and articles, such as mats, hats, vegetable ivory, etc., are exhibited in the original museum, now called Museum No. II. Thus it may now, I believe, be said with full truth that it is almost impossible to point out any Colonial product, however insignificant, which is not adequately represented in the Kew Museums.

No. III Museum. the home of Tropical Timbers in particular, was formerly the Orangery of the original Royal Gardens; while No. IV. Museum, our most recent acquisition, which contains a remarkable collection of British-grown timber, and the articles made therefrom, as well as a complete series of the fungus and insect pests to which trees are subject in this country, has been housed in Cambridge Cottage. This building was formerly the private residence of His Royal Highness, the late Duke of Cambridge, and was after his death graciously made over to Kew by the Crown, and opened to the public in 1910.

Three of our Museum Buildings, as I have mentioned, are none too well suited for their purpose, since they were not built for the display of museum specimens, still, they serve their function very fairly well. No. I. Museum was enlarged in the year 1881, and both it and No. II., which is the least suitable for a museum, are now inconveniently crowded. It is to be hoped that before long a further enlargement of No. I. Museum may be sanctioned on such a scale that not only the crowded out products derived from the Dicotyledonous plants can be included, but also the Monocotyledon exhibits now displayed in No. II. Museum. If this should ever be sanctioned, then the whole range of vegetable products, exclusive of the timbers of the world, could be studied under one roof, in proper systematic sequence.

What, it may be asked, is the purpose of these collections, and in what way are they connected with the work of Kew? Their chief object is to show the practical applications of botanical science, and to enable students and those engaged in commercial pursuits both at home and from overseas, to appreciate the general relations of the vegetable world to man, and in particular to exhibit the vast resources of the Empire. We learn from them the sources of the innumerable products furnished by plants for our use and convenience, whether as articles of food, of construction and application in the arts, of medicine or curiosity. They also show us the points where we need further information, more especially as to the origin of many valuable timbers, fibres and drugs.

In short, not only do these collections tell us how much we have already discovered, but also how little we still know of the extent to which herbs, shrubs and trees contribute to our necessities, comforts and our numberless requirements.

Closely associated with the Museums, as it is also with the garden proper and the work of the Herbarium, the Jodrell Laboratory must now be mentioned. Here, thanks to the munificence of Mr. T. J. Phillips Jodrell, who built and equipped the Laboratory at his own expense in 1876, we have a department where work can be undertaken to determine the structure, functions and properties of obscure vegetable products, and it is seldom that it is not possible by means of careful research, to solve the problems which are constantly being presented to us by our correspondents both at home and abroad. Without the wealth of material in the Museums and the Herbarium for comparison and examination, the many valuable results which have been achieved in this laboratory would not have been possible.

The Laboratory is also fitted for physiological and mycological investigations, and some famous researches by distinguished botanists have been carried out within its walls. Research students are welcomed here, and are able to study, as nowhere else, the problems presented by the vegetation of the globe illustrated, as it is, by the collections of living and preserved plants in the Royal Botanic Gardens.

The North Gallery, built and presented by Miss Marianne North, in 1885, is also an appanage of the Museums, and, as is well-known, in this remarkable botanical picture gallery plants from all over the world may be seen painted in oils by her master hand. The pictures are renowned for their botanical accuracy as well as for their artistic skill, and these qualities render them of infinite value in a scientific establishment like Kew where an attempt is made to grow, portray, preserve and study as fully as possible the wonders of the vegetable kingdon.

A smaller collection of pictures by Miss M. H. Mason, of South African plants, in Museum No. IV., may also be referred to here, since they enable us to appreciate very clearly the special characteristics of the vegetation of South Africa.

This brings me to the fourth department, the Herbarium. The present Herbarium collections, as I have stated, owe their origin to Sir William Hooker, since those earlier and famous collections made by Sir Joseph Banks and the Kew Collectors, are now at South Kensington.

When Sir William came to Kew, he brought with him his own large collection of dried plants, and in 1854 this was greatly augmented by the collections of the distinguished botanist, Mr. George Bentham, who presented his fine private Herbarium and Library to the Nation. This nucleus has been continually added to by official contributions, by exchanges and by the judicious expenditure of our small annual parliamentary grant voted for the purpose, so that now the Kew Herbarium contains between three and four million specimens.

In the Herbarium, which is the largest and most completely organised in the world, in addition to the collection of dried specimens, we possess a magnificent collection of coloured botanical drawings of plants, so that not only can a large number of the plants of the globe be studied in the living condition, and as pressed specimens, but they can be examined as delineated by botanical artists, both as they have flowered at home, and also in many cases (Miss North's pictures) as they grow and flower in their native countries.

Such botanical studies are of very great assistance to the work performed at Kew in connection with the Floras of the different parts of the world.

The work carried out in the Herbarium is one of the most important of the functions of Kew. What exactly that work is may be gathered from a perusal of the pages of the *Kew Bulletin* for the year 1905, compiled by Sir William Thiselton-Dyer. In addition to the attempt that is being made to complete a botanical survey of the Empire, detailed researches are being undertaken in connection with the floras of the world, and particular attention is always being paid to the determination of plants which may prove to be of economic importance, whether as food or for use in the arts, and which might be introduced with advantage to one or other of our overseas possessions.

Unless a plant, which may possess definite economic possibilities, has been identified botanically, it is quite useless to attempt its introduction to cultivation without incurring the grave risk of bringing in a worthless plant. The more we get to know about plants, and the more we discover how considerable a range of variation they exhibit, both as regards form and in their constitution, the more we understand the importance of arriving at an exact determination of the particular species or of some special varietal form which it may be desirable to introduce in order that it may be a commercial success.

Had it been appreciated earlier that species show fundamental physiological variations, which are often only rendered apparent by experiment in the laboratory, as well as the more easily discernible morphological variations, much labour and money might have been saved.

I may instance two examples which affect the British Empire, with both of which Kew has been intimately concerned.

In the one case, that of Camphor, the product derived from *Cinnamomum Camphora*, Nees, native of Formosa and Japan, Kew must plead ignorance. In the other, that of Para Rubber *Hevea brasiliensis*, Muell. Arg. the blame must be attached to the rubber growers. They failed to appreciate the fact that science could help them in selecting the best trees to cultivate in their plantations and thought that from the seeds of any tree of *Hevea brasiliensis* they would obtain the plants they required. Scientific research, however, has shown that the percentage of latex yielded by individual trees varies very greatly in amount, for while some trees yield only 2% of latex, others yield as much as 40%. Had the warning note which was sounded by Kew and by others been regarded, which was, that seed from untested trees should not be sown promiscuously, rubber plantations to-day might have been furnished with a larger proportion of the best latex-yielding trees than is now the case.

With regard to Camphor, it is only recently that it has become known in the West that there are two varietal forms of the Camphor tree, both so alike in their external botanical characters that they can hardly be separated. One of these yields the valuable solid camphor on distillation, the other camphor oil, a product of little commercial use. Since Camphor can be cultivated in several British Colonies, seed was obtained through Kew for growing in Mauritius, the West Indies and other Colonies. Unhappily, however, the seed which was procured emanated from the oil-producing trees, which were well-known to the senders, so that, except in a few isolated cases, there are scarcely any true Camphor trees in the British Colonies.

Problems of this nature abound in the realms of economic botany, as for instance, the exact determination of the best type of Willow for making cricket bats which was worked out at Kew, or in the domain of textiles such as the finding of the best strains of Cotton, New Zealand flax, Sisal or other fibre plants, which from time to time are temptingly brought to the notice of the prospective investor.

Several forms are known, both of Agave and Ananas, as members of this society are well aware, which are of little value for fibre production, and such are clearly recognisable by their botanical characters. It is in questions such as these that a botanical institution like Kew, with all its resources, can afford so much assistance to industry if only those concerned in commerce will seek our aid.

The principal work of the Kew Herbarium, however, is, as I have said, the systematic investigation and description of the floras of the world, and in particular, those of the British Empire. Owing to our close connection with India and the Colonies, vast collections of plants have poured in from every quarter, and it is the work of the Herbarium staff to name, preserve and arrange them so that they may be available for reference and study.

It is a matter of regret and a serious handicap to the full measure of our usefulness, that, despite additions to our staff, the influx of new material has ever been greater than could be absorbed, even with the most unremitting energy.

Both the Home and Colonial Governments and the Government of India have been generous in affording financial assistance to enable us to tell them of the wealth and potentialities of their floras. But you will, I feel sure, agree that far more help is required if Kew is to maintain its proud position as the premier botanical establishment of the world, when I tell you that in our stores we still have accumulations of preserved material, largely from the Empire, amounting to some 200,000 specimens. This position, which it must be our earnest endavour to uphold, when British interests are so immense both in the domains of pure and applied botany, can perhaps best be maintained by the generosity of private benefactors, and should there by any happy chance be such an one among my audience, I can assure him that assistance of this nature would benefit humanity at large to no small degree. I may mention here that the great American Institution, the New York Botanical Garden at Bronx Park, has received very large sums in the way of private benefactions, the number and magnitude of which fill me with envy.

Science never likes to beg, but should there be anyone anxious to help forward a great task, I would commend to their notice the work which, thanks to the generosity of Charles Darwin, has been undertaken at Kew. I allude to the *Index Kewensis*, that great register of all the species of plants, giving their habitats and references to the place and date of publication, of which five supplements have now been published in addition to the four original volumes produced at Darwin's expense. I may mention here that we estimate that the VIth quinquennial supplement of the *Index* will contain some 35,000 entries of new species, while in the Vth supplement, published in 1921, 37,000 new names were registered. These figures, together with those I have given of the number of our herbarium specimens, will perhaps indicate something of the magnitude of the work that is being undertaken in the Herbarium, and in particular of the heavy tax on our resources that the preparation of the *Index* entails; a work that is indispensable to botanists and horticulturists throughout the world.

I must not omit to mention, however, that Kew does receive some valuable help from the Bentham Trustees, who administer the legacy of that illustrious botanist, Mr. George Bentham, who left a sum of money for the purchase of books and specimens for Kew.

What, however, has been achieved at the Herbarium in addition to the labours I have already sketched? I can best answer by pointing to the long rows of the Colonial and Indian floras, and such ancillary works as "The Dictionary of Economic Products of India," and "The Useful Plants of Nigeria," all of which have been prepared at Kew.

The proposal that a series of Colonial floras should be compiled at Kew was made by Sir William Hooker as long ago as 1863, and it is of interest to compare his proposals which were made public in the *Annals of Botany* for 1902 (p. lxxxiii) with the results that have so far been accomplished.*

COLONIAL AND INDIAN FLORAS.

Sir W. Hooker's proposals.	Volumes.	Present position.	Volumes.
1. Australian Colonies including Tasmania.	8.	Flora Australiensis.	7.
2. South African Colonies.	10.	Flora Capensis.	10.
3. British North America, Pacific to Atlantic.	2.	(Not prepared).	
4. West Indian Colonies.	2.	Flora of the British West Indian Islands. (A new work is now needed.)	1.
5. New Zealand.	1.	Handbook of the New Zealand Flora.	1.
6. Ceylon.	3.	Handbook of the Flora of Ceylon.	5 and 1 quarto volume of plates.
7. Hongkong.	1.	Flora Hongkongensis.	1.
8. Mauritius and the Seychelles.	1.	Flora of Mauritius and the Seychelles. (A new work is now needed.)	1.
9. British Guiana.	2.	(Not yet commenced).	
10. Honduras.	1.	(Not yet commenced).	
11. West African Colonies.	2.	Flora of Tropical Africa.	2.
12. British India.	10.	Flora of British India.	7.

---

* "The Life of Sir William Jackson Hooker," by Sir Joseph Dalton Hooker, in the *Annals of Botany*, Vol. XVI., No. LXIV., Dec., 1902, which gives a vivid account of Sir William Hooker's work at Kew. *See also Kew Bulletin*, 1905, p. 20.

In addition to these the following Floras have already appeared, or are in course of preparation, and have been prepared wholly or mainly at Kew:—

1. Materials for the Flora of the Malay Peninsula.	6 volumes.
2. Flora of the Malay Peninsula. (in preparation, 2 vols. issued)	5 volumes.
3. Flora of the Upper Gangetic Plain. (1 volume to complete)	3 volumes.
4. Flora of the Presidency of Madras.	5 parts (under continuation).
5. Flora of the Presidency of Bombay.	2 volumes.
6. Index Florae Sinensis.	3 volumes.
7. The Commercial Products of India.	1 volume.
8. The Useful Plants of Nigeria.	4 parts.
9. The Flora of West Africa (in preparation).	
10. Floras of Bermuda, St. Helena, Ascension, Tristan da Cunha were published in the Scientific results of the Challenger Expedition.	
11 Sketch of the Forestry of West Africa (Moloney)	1 volume.

A proposal to prepare a Flora of Trinidad has been under consideration for some time, but it has not yet been found possible to undertake this very desirable piece of work.

In place of Sir William Hooker's proposed "Flora of the West African Colonies," "The Flora of Tropical Africa" has resulted, and is now nearly complete, comprising eleven volumes. So greatly has our knowledge extended, of the flora of our West African Colonies, that it has been found necessary to ask the Governments of our four West African Colonies, The Gambia, Sierra Leone, The Gold Coast and Nigeria, to subsidise the preparation of a "Flora of West Africa." This proposal, I am happy to say, has received the approval of the Secretary of State for the Colonies, and of the Colonial Governments, and work was commenced in September last on this new undertaking. When this new compact Flora is published, it will, I believe, be possible, not only for the botanist but for all interested in the vegetation and vast botanical resources of West Africa, to determine the plants they meet with, and learn something of their economic possibilities.

The floras of Trinidad, and the splendid vegetation of British Guiana and British Honduras, and, strange as it may seem, the flora of Canada, still await attention; and, as might be expected, the earlier volumes of the Flora Capensis published between 1859 and 1865, require to be almost entirely re-written, so greatly has our knowledge grown of the vegetation of South Africa in recent years. Similar remarks apply to the Floras of Mauritius and of the West Indies.

Thus, though much has been accomplished, even more remains to be done, and, as in every other branch of science, it is not possible to foresee any termination to our activities, but rather each accession of new knowledge opens up long vistas and enlarged spheres of useful and necessary work.

Not only do we deal in the Herbarium with the flowering plants and ferns, but with the mosses, lichens, seaweeds and fungi of the world as well, and such matters as the serious Panama disease of bananas, the coffee leaf disease (*Hemileia*), which devastated the flourishing coffee plantations in Ceylon, and other noxious or less harmful plant diseases from time to time demand investigation on the part of our scientific assistants.

Every post brings some enquiry of interest, and frequently one which necessitates careful and laborious research, or, on the other hand, it may open out some possibility of utilising a new economic product for the benefit of one of our distant Colonies.

We are prepared to report upon and obtain advice with regard to new vegetable industries, though it may relate to so small a matter as the supply of West African palm kernels for carving into coat buttons, or as to the value of a pithy stem as a material for a razor strop, on which—before the days of safety razors, I need hardly say—Kew reported to a West Indian Government, or even, quite recently, as to the botanical identity of the wood of a walking stick, about which its owner, as we discovered later, had made a bet!

I must, however, return to the garden side of Kew in order to illustrate more fully our close connection with the Colonies and India.

It was through Kew, as I think it is now well-known, that the Para rubber industry of the East was founded, and that the cultivation of Cinchona in India, Ceylon and Jamaica came about. This latter enterprise had been urged by Sir Joseph Banks more than half a century before.

These two remarkable introductions of South American economic plants were made possible through the assistance given by Kew to the two enterprises, for the seeds of both plants were despatched to Kew from their native countries (*Hevea* in 1876, *Cinchona* in 1861), and the young plants which were raised in our greenhouses were despatched in Wardian cases to the East, where they now flourish. In the one case, the successful achievement has brought very large financial returns, and in the other, the possibility of sound health in the tropics to a vast number of people.

I might give an account of many other projects that Kew has undertaken did time permit, such as the introduction of the very useful Teff grass from Abyssinia to South Africa; the annual sending of Mahogany seeds from the West Indies to India, and the building up there of Mahogany forests; the advice and help which Kew has afforded to the experiment in afforestating the barren tree-less Falkland Islands, and the sending of seeds and cases of useful plants to the Islands of Ascension and St. Helena with the result that Ascension is now furnished with useful thickets of trees. Kew has also rendered assistance which has been of value in setting up the lucrative Onion-growing enterprise in Antigua, and in connection with the making of paper from the "Ginger Lily," *Hedychium coronarium*. Then, again, reference must be made to the sending of Cacao plants to the Gold Coast since the success of the Cocoa plantations there is largely due to the assistance and advice afforded by the Royal Botanic Gardens.

Interesting stories about many other economic plants, valuable for their fibre, for paper making, spices or drugs, or for their food value, with which Kew has been intimately concerned, could also be related. I must, however, pass on to the consideration of a further sphere of usefulness to which we attach great importance, and which has been attended with far-reaching results; that is, the work of completing the botanical and horticultural training of the young men who come to Kew for a period of two or three years as Student Gardeners.

In this respect Kew may be regarded as a University of Horticulture, and perhaps more particularly of Tropical Horticulture, since so many of her sons go out to every part of the Empire to carry on the science and practice of Horticulture in the Botanic Gardens and Agricultural Stations in the Tropics.

That this should be the case is only natural since in no other Institution in this country can so much be learned about the vegetation of the Tropics, and the proper method of cultivation of tropical economic and other plants. Men trained in botany and agriculture in our Universities are no doubt well equipped in the scientific principles underlying their subject, but they are perforce sadly handicapped, owing to their lack of practical knowledge of the plants which they will meet with in our Colonies in connection with their work.

With the growing and legitimate demand for men who have passed through a University on the part of the Colonial Governments, the men trained at Kew are often placed in a difficult and unfavourable position, but I venture to say that the best of our students will be found, in the long run, with their practical knowledge added to the theoretical instruction provided for them at Kew, to be able to hold their own in comparison with the men who have had better opportunities in the way of a course at a University or at an Agricultural College

Neither class of men, I would submit, are entirely satisfactory for sending out straight from home to some distant Colony where they will be confronted with problems with which they are, to a great extent, unfamiliar, but now that the Imperial College of Tropical Agriculture has been so successfully established in Trinidad, I am convinced that at last we have the opportunity of completing the education necessary both for the University candidate and for the man trained at Kew, so that they may become efficient scientific officers qualified to serve in whichever of our Tropical Colonies or Dominions their services may be required.

I have recently had occasion to bring this aspect of the training of scientific officers for colonial posts to the notice of the Secretary of State for the Colonies, and I hope that my proposals may meet with His Grace's approval, and that they may also be favourably considered by the Governors and Directors of Agriculture of our Colonies.

The important part that Kew has played in the past, and I am glad to say is still maintaining, in sending out her sons to distant lands in Government service, is, as I have indicated earlier, in direct continuity with the policy initiated by Sir Joseph Banks over a century ago, when Kew men were sent to take charge of the Botanic Gardens in Ceylon, St. Vincent and Trinidad.

The connection between the Royal Botanic Gardens, Kew, and the many daughter Botanic Gardens and Stations overseas—which have now very generally become the centres of flourishing Agricultural Departments—has been of inestimable benefit both to the Home and to the Colonial Institutions, and has served to weld that link of union and mutual help and sympathy which it is so essential to preserve.

Before leaving this portion of my subject, I may perhaps be allowed to mention that at the present time among the higher posts held by Kew men in the Colonies, one of our former student gardeners is Director of Agriculture in the Gambia and another is Commissioner of Lands and Forests, Sierra Leone. Another is Superintendent of the Botanic and Forestry Department, Hongkong, and the Economic Botanist, Trinidad, also received his early training at Kew, while the Superintendents and Curators of almost every one of our Tropical Agricultural Stations and Botanic Gardens have passed through Kew. In the United States of America it is of interest to note that Kew-trained men are held in high esteem. One is now Assistant Director of the famous Arnold Arboretum, and several others hold important horticultural appointments in that country. The value of the Kew training is further emphasised by the fact that several of our Scientific Assistants received their early training in the Gardens, including the present Assistant Director, who, before returning to Kew last year, held important posts in the Gold Coast as Assistant and Deputy Conservator of Forests and in Singapore as Assistant Director of the Botanic Gardens.

I cannot close this account of the work of the Royal Botanic Gardens without a brief reference to the building where all the various activities are centred, namely, the Director's Office; a small and unpretentious building of great interest from its historical associations. I believe the Director of Kew has been compared to a spider at the centre of his web, and the comparison is not altogether inept, since he has to keep in intimate touch with all the threads of the work in progress in each of the separate departments, and with all the important matters raised by correspondents at home and abroad. It is also his duty, and it is a very pleasant and interesting side of the Kew work, to keep himself informed as to the progress of botanical and agricultural affairs in India, the Dominions and the Colonies, and to do whatever may lie in his power to help forward their various enterprises.

The crowded shelves on the walls of the Director's room afford some evidence of the nature of the work, as any visitor to his office can see, for every folio bears in large letters on its back the name of some dependency of the Crown or of a subdivision of India, or of a Dominion. In fact, a stranger might well think that he had inadvertently entered the office of the President of the Royal Geographical Society or the room of the Secretary of State for the Colonies in mistake for the Director's Office at Kew.

The average daily post bag also reflects very clearly the Imperial nature of the work of Kew. Letters and parcels come from every part of the world, and may relate to such varied subjects as the possibility of introducing the mulberry tree to British Honduras; the Panama disease of bananas; the suitability of Newfoundland lichens for reindeer food; the precautions that should be taken to prevent undue destruction of the oil palm in West Africa; the identity of the seeds in a mixture of chicken food, a query possibly involving some legal action; or as to the botanical identity of a tropical plant about which all information is withheld by the senders, who we subsequently find are interested in the promotion of a company for its exploitation. In the latter case, I think the enquirers would be a little disturbed did they know how much we had been able to discover about their plant, bearing some camouflaged name, both as to its country of origin, chances of success under cultivation and so on.

There is also the extensive and more purely scientific correspondence to be attended to with botanical establishments on the Continent and in America, Java and the East as well as with our colleagues in our home universities and colleges.

Visitors, too, are sometimes almost as numerous and varied as the letters, for like them they come from every part of the world, and serve as a pleasant reminder that the work of Kew is appreciated throughout the Empire, and their visits to Kew help to strengthen that tie of mutual sympathy and intercourse the value of which we fully realise. That several members of the staff have personal acquaintance with most parts of the world enables Kew to give more useful advice and criticism than might otherwise be possible.

I hope I may have been able to give you some small idea of what the work of Kew really is, and that though this work is pre-eminently scientific, Kew is, nevertheless, keenly alive to the interests that make countries prosperous and wealthy. In the words of Sir William Thiselton-Dyer—which are, I believe, as true now as when they were written over forty years ago—Kew "has itself grown and flourished under its past and present Chiefs . . . not so much from its dependence upon their merits, but rather because the principles of its administration have been essentially British and practical.

"It has steadily set itself to do every kind of public work which is connected with botanical science.

"It was never launched with a theoretically complete equipment and constitution, but it has slowly earned every advantage that has been conceded to it, and, as its labours have been enlarged, so its capacity for their performance has been increased."

The following testimony, extracted from a speech by Mr. Joseph Chamberlain in the House of Commons on August 2nd, 1898, will show how much, in the opinion of the most famous of Colonial Secretaries, the Colonies owe to Kew: "I do not think it is too much to say that at the present time there are several of our important Colonies which owe whatever prosperity they possess to the knowledge and experience of, and the assistance given by, the authorities at Kew Gardens. Thousands of letters pass every year between the authorities at Kew and the Colonies, and they are able to place at the services of those Colonies not only the best advice and experience, but seeds and samples of economic plants capable of cultivation in the Colonies."

I have attempted to show how much of what Kew has become is due to the initiative and foresight of Sir Joseph Banks and Sir William Hooker, and I think if it were desired to place an inscription beneath a monument to either of these great men, relating to their work at Kew, the following verses from the Book of Ecclesiasticus, which refer to "Wisdom," might very fittingly be selected:—

"I came out as a brook from a river, and as a conduit into a garden.

"I said, I will water my best garden and will water abundantly my garden bed; and lo, my brook became a river, and my river became a sea."

DISCUSSION.

THE CHAIRMAN said that they had listened to an exceedingly interesting and very complete account of a famous Institution. He supposed that Kew and perhaps the waxworks in Marylebone Road were the two best-known places in London, not only to the provincial, but to the foreigner. He had often been surprised, while talking to foreigners in different places, by their knowledge of Kew, which was the one place that they wanted to come to England to see. It was no little privilege to be associated with a Garden such as Kew, and he entertained a certain envy of the lecturer. Dr. Hill had told them something of the history of Kew during the last 150 years. In seeing Kew to-day one was sometimes apt to forget the wonderful services which had been rendered to the Garden in time past by the pioneers, especially the two Hookers, father and son; and there were many other botanists that one might mention whose names came to mind. He remembered Sir Joseph Hooker in one or several of his letters complaining that the young botanists of his day did not know their plants, and the speaker was afraid that this was still true of some of the older botanists. Many botanical students, while having an intimate acquaintance with the insides of plants, had only the slenderest knowledge of their outsides. He himself had been more or less brought up in that sort of school. He was not going to complain of his teachers, because he felt nothing but gratitude towards most of them; but it was the fact that at that time—and he was afraid that the schools were yet not quite free from the reproach—one learned a good deal of the microscopic characters of plants without knowing what the plants themselves looked like. Students could improve their education at Kew in that respect. One thing that always struck him about Kew was that it appealed to every sort of person, not only botanists, but all men who had any aesthetic sense (and most people had some). The botanist himself approached Kew with a sense of awe, while the ordinary non-botanical person who went there, probably walked about as if the place belonged to him. He himself remembered going to the Director's office—long before the time of the present Director—in fear and trembling, though he found when he got into his presence that the Director was a human being, and indeed his experience had always been that the Directors of Kew were essentially human. So long as that state of affairs continued, the fortunes of Kew might safely be left in their hands. A great deal had been heard that evening about the work which Kew had done and was doing—its variety and utility. But he thought that Kew might even do a little more than it was doing, and he hoped that in future it would develop along new lines of activity. There was still room for expansion at Kew on the experimental side, and the best wish one could express for its future was that it might go on developing in the future with the same rapidity as in the past. They had been told that evening that science never liked to beg. As a matter of fact, he thought that the lecturer had begged very nicely, and he would be very glad—he did not wish to appear as a rival beggar—if an additional endowment could be obtained for that wonderful book, the *Index Kewensis*. That was a work to which every botanist owed a great deal, and to which he turned very frequently for information, and he would like to support the appeal which had been so delicately made that evening by the Director of Kew.

Professor F. W. Oliver, F.R.S., said that the Chairman had called upon him to speak probably because he knew that the first half of his life was spent in the Gardens as the son of an official, and that he could speak quite freely. He had always been an admirer of Kew, as well as its critic. His criticisms, however, he reserved for private consumption. Nor was he going to indulge in reminiscences of those early days when he lived in the Gardens, except to say that his recollections of fifty years ago were extraordinarily vivid because Kew to him then was naturally the centre of his world, as well as the centre of the botanical world. In the sixties and seventies of the last century the dominant element in botany was the systematists. They occupied all the principal positions in the botanical world, and with them resided the power of conferring appointments upon others. If at that time a botanical post was desired one naturally made friends with the Hookers or their successors. That state of affairs had gone and could never return on account of the enormous subdivision and development of the branches of botanical science. But in those days the whole botanical world used to come to Kew and reside for a week or a month or more on Kew Green, especially in the Long Vacation. Dozens of the most eminent botanists, British and foreign, were to be seen there. All this left an indelible impression on his mind, the more so because they used to talk quite freely to him, and say what they thought of Kew. They agreed that it was a most wonderful place, and then they held up their hands and said, "But, you know, the whole thing is simply wasted. Not more than one per cent. of the resources and material at Kew is utilised in any way whatever in the advancement of knowledge." What they meant was that all the plants that could be grown in the world were being grown at Kew, but that was all; the harvest was rich, but the reapers were few. The other point he remembered was this, that he and others would utilise Kew in an illegitimate way—bird-nesting, for example. Kew had an extraordinary range of birds and bird-nests, and he learned most of his ornithology in Kew Gardens. Occasionally he would use a gun for shooting game birds, sometimes even out of season! But one felt that Kew at that time sadly lacked the element of youth. This systematic aspect of botany got a little bit upon one's nerves. One of the most happy episodes in the development of Kew was the foundation of the Jodrell Laboratory, to which Dr. Hill alluded, and particularly the association with it of Dr. Scott. When the history of botany at the end of last century and the beginning of the present century came to be written the work done in the Jodrell Laboratory connected with Dr. Scott would receive full justice. His was a most extraordinary output from one man, and the number of young people he interested in the subject of botany as a whole was quite remarkable. Almost every botanist for the last forty years had passed under the influence of Dr. Scott, and lasting and extraordinary benefits had resulted to all of them. The speaker's last point was to suggest that something in the nature of an *entente* might come about between Kew Gardens and, if not a university, a sort of department of botany or botanical institute, which would have the privilege of using Kew and advancing the knowledge of the subject. He was not implying any blame to anybody, but it was perfectly impossible for the officials of a Garden to succeed in the double duty of administration and of advancing to the full the knowledge of the subject. At one time he was almost thinking of getting up a syndicate to carry out this idea—in other words, to acquire Gloucester House close by and convert it under a syndicate into a botanical institute; but that never came to anything, and the building was taken over as a college for the training of miners and other working-men who became leaders of labour. Any such development might not come within the next twenty or thirty years, but he felt sure that at some time or other an educational side would develop in connection with Kew, in the most friendly relations with the Gardens, and yet not under their authority. Kew was a Government institution, and it was out of the question to have an educational body under the orders of a Government office, although too often one found that such was the relationship. The name of Sir Joseph Banks had been mentioned that evening. Banks was not merely a botanist, he moved in the great world and knew everybody. Those who had read the Farington Diaries, lately published in the *Morning Post*, would have noted with pleasure the frequent appearance of Sir Joseph Banks, not only in social engagements, but on his travels, in his illnesses, and at his eatings and wine-drinkings. The Diaries showed that Banks was very human, in which respect he resembled the Directors of later times. Those must have been great days, when men were still in touch with the tradition of Linnaeus, who made the subject of botany more popular, he supposed, than it had ever been before, and certainly than it had ever been since. Linnaeus made certain aspects of botany at once accessible to common men. There was no more fashionable pursuit 160 years ago than the study of botany. Whether those days would ever come back again or not it was impossible to say; probably they would not.

Dr. J. A. Voelcker said that he could not claim, like the last speaker, to have spent his early days at Kew. He had to speak rather from the point of view of the ordinary visitor, and as such he would like to be the medium of expressing the great indebtedness of the public to those who directed such a place as Kew. He did not know what others thought, but he had often remarked, on his periodical visits, that he always came away feeling that he had got something for the payment of his imperial taxes! Whether people simply walked round and enjoyed the sight of the plants and the museums and ended up with tea at the Pagoda, or whether they went with more serious intentions, they must always feel, he thought, that they had got something for being citizens of the Empire. But for those who knew the subject more closely there was a much wider sphere of interest at Kew, and it was very instructive to have heard from the Director himself an account of the history and of the present activities embraced under the name of Kew. If he might be allowed as a layman to speak from his own experience, he would like to acknowledge the courtesy and the readiness to help which resulted from addressing inquiries to Kew. In his own agricultural work he had had from time to time to refer questions to Kew, and it was almost unnecessary for him to say that the officials there were willing to go to endless trouble in satisfying the requests of those who applied to them. The British public did not fully know of this; they did not realise that institutions such as Kew were there for the purpose of affording information to inquirers, and the number of questions which the obliging officials there were able to answer was remarkable. We needed to be reminded that Kew was a national possession. It was one of the places to which we had a right to go, and if the public did not use the stores of information available, the fault was that of the public and not of Kew. At all events, he could say for the Directors of Kew Gardens, and now for the present Director, that they were always willing and ready to afford information to those who inquired. He could bear out from his own experience what Dr. Hill had said with regard to the influence of Kew in other parts of the Empire. It had been his lot to travel about in India, and wherever he went he found a number of people in constant touch with Kew. The Gardens at Calcutta, Saharanpur, and elsewhere were in regular correspondence with Kew. The same thing obtained in the West Indies and elsewhere. All this formed part of a vast system for the gathering together of information which was for the benefit of science, and which also served commercial interests. There were a large number of cases in which the accumulated knowledge of Kew, from purely scientific sources, had been devoted to the expansion of commercial interests. Science was not valued purely for its own sake, but for the extent also to which it could be used in the general service. He had been interested to hear of the different changes that Kew had gone through in its time, how the original plan was conceived and carried out, and how it then underwent a period of decadence, when another institution, the British Museum, came up and secured the early records of Kew. He did not know that that was altogether a bad move; it was not always a mistake to have two institutions, one keeping the other up to the mark. At all events, the old plan had been reverted to, and the system of having collectors and correspondents all over the world had been retained, and all who had listened to the lecture that evening would wish good success to that work.

Mr. E. Shine said that in the Ministry of Agriculture he had the pleasure of working with the Director of Kew. The Director had rather slurred over, in his paper, the connection with the Ministry of Agriculture, and he for his part only wished that the Ministry of Agriculture had the same interesting dealings with Kew that, he understood, the Foreign Office, the Colonial Office, and other departments of Government had. The Ministry of Agriculture's concern at Kew often related to such dull questions as to whether perambulators should be permitted to go into the Gardens, and whether the entrance fee should be a penny, twopence, or nothing at all. The Ministry of Agriculture was very glad to be connected with a department like Kew Gardens, which, he thought, was always in favour with the general public. At the Ministry they were so accustomed to people finding fault with them on such questions as rabies, foot and mouth disease, and so on, that it was quite pleasant to hear everybody exclaim that everything in the garden was lovely! So far as the officials at the Ministry were concerned, their relations with the Director and officials were always most harmonious, and they welcomed at the Ministry the privilege of being associated with them.

The Secretary said that there was one small point to which he would like to draw attention. The Director of Kew had referred at the beginning of his paper to the introduction of the bread-fruit tree to the West Indies. The speaker merely wished to point out, as a sort of foot-note to the paper, that the whole question of the conveyance of that bread-fruit tree to the West Indies was due to the work of the Society. Sir Henry Trueman Wood, in his History of the Society, related how Sir Joseph Banks, who was a member, took a great interest in this question, and it was on his suggestion that a prize was offered with this particular object. As a result of that prize, Captain Bligh undertook his expedition on the "Bounty." He failed the first time, but on his second expedition, in 1793, he succeeded. On his return he sent in a full report of the whole affair to the Society, and as a result of that he was awarded the Gold Medal.

The Chairman felt sure that the audience would wish to express its hearty thanks to the Director of Kew. He could only say for himself that although he had been more or less familiar with Kew for some time, he had been somewhat ignorant of its past history, and had not realised the full extent of its activities until that evening. It would be a great advantage to many to have this paper in a form in which it could be readily referred to, and he was very glad that it was going to be printed in the *Journal*. It would be a most valuable paper for reference.

A vote of thanks was passed unanimously.

DR. HILL briefly acknowledged the compliment, and the meeting terminated.

NOTES ON BOOKS.

LIFE OF SIR WILLIAM WHITE, K.C.B., F.R.S., LLD., D.Sc. By Frederick Manning, with an introduction by The Rt. Hon. Lord George Hamilton, G.C.S.I., LL.D., D.C.L. London: John Murray. 1923.

Sir William White died in 1913 at the age of 68, so that it is time for his life to be written, if it is to be read by any of his contemporaries. Not very many of them can still survive, and the list is rapidly diminishing. One of them, Lord George Hamilton, fortunately is still alive and contributes, as an introduction to this volume, a warm and generous appreciation of Sir William's character and public service. Lord George and Sir William White were born in the same year. One was First Lord of the Admiralty when the other was appointed Director of Naval construction, and the mutual liking and admiration conceived by each for the other continued till Sir William's death.

Sir William White's life just synchronised with the era of change brought about by the introduction of steam as a motive power, and the substitution of iron for wood in the construction of war-ships. The first work on which he was employed as a dockyard apprentice was the conversion of a sailing ship into a screw-propelled steamer. When he resigned his post at the Admiralty, British war-ships had become the huge swift engines of destruction which saved the country from invasion in the great war which began a year after his death.

From the time of Elizabeth till the day of Trafalgar, there had been no great change in our ships, and in the half-century which followed Trafalgar the improvement had been but small. Now, a single modern line-of-battleship (given, of course, a sufficient supply of ammunition) could send to the bottom, herself uninjured, the great Armada and the English ships which drove it to destruction, or the combined fleets which fought at Trafalgar.

It is not, of course, suggested that these great changes were in any sense due to Sir William White. Things would have taken the same course had he never lived, and even when they were modified by individual direction, he was only one of many whose influence affected the direction of change and its character; but he took his full share of the work. To call him "the greatest naval architect this world has ever seen," is to make rather a strong statement, but certainly among his contemporaries he had few, if any, equals, and certainly no superior.

He started in life as a dockyard apprentice, after a discussion, it would appear, between some of his friends as to whether he should not be trained for the Baptist Ministry. Fortunately, alike for the boy and for the public service, the wiser counsel prevailed and he entered the Royal dockyard at Devonport in 1859. Not very long after his apprenticeship (in 1869), the School of Naval Architecture was founded at South Kensington and White was one of the candidates selected from the various dockyards. He passed at the head of the list in the competitive examination and remained at the school till he entered the construction department of the Admiralty in 1870. In the same year the School was merged in the Royal Naval College at Greenwich, and White, who had become Instructor of Naval Architecture at the school, became one of the Lecturers at the College.

At the Admiralty he remained till 1883 holding various appointments, the highest being that of Chief Constructor. In that year he received an offer from Sir William Armstrong which led to his employment by the great Elswick firm. With them he remained till 1885, when, on the resignation of Sir Nathaniel Barnaby, he was recalled to the Admiralty as Director of Naval Construction. White's acceptance of this post was a distinctly patriotic act, for in spite of its high distinction, its emoluments were less than he was receiving, and would have received at Elswick. If he had remained at Armstrongs he would certainly have died a much richer, and probably a happier man. The service of a great commercial firm is free from many of the drawbacks of service under superiors whose actions and decisions must of necessity be influenced very largely by political considerations; and besides discharging the duties of a difficult post, he had to meet the parliamentary criticism of a former holder of the same office, neither an easy nor an agreeable task.

The policy of the Admiralty, and the work of its construction department were the subject of vigorous, even violent, controversy, alike Parliamentary and professional. The Director of Naval construction was not only permitted, but expected to take his part in it. This White did with much effect, both at the professional associations, such as the Institutions of Naval Architects and of Civil Engineers, and before more popular audiences in his lectures and addresses at the Society of Arts, and the British Association.

He held his office till 1902, when he resigned. His resignation, partly due to failing health, was precipitated by a blunder made in the construction of a Royal Yacht, for which he was nominally though not actually, responsible. The work which he carried out during his 17 years' tenure of office is described in full detail by Mr. Manning, and the record is a long and honourable one.

When he left the Admiralty he was disposed to retire entirely from further work, but the advice and solicitations of several warm friends induced him as his health recovered, to resume. He became a Director of the firm of Messrs. Swan and Hunter and in that capacity assisted in the design and construction of the two great Cunarders, Mauretania and Lusitania.

He was President of the Civil Engineers in 1902, and was President-elect of the British Association at the time of his death. He was Chairman of the Council of the Royal Society of Arts in 1908, and was one of its Treasurers at the time of his death. The warm interest he took in the Society during the closing years of his life was increased by the fact that as a boy he had been very successful in its examinations and had taken a number of certificates.*

Reference has already been made to Lord George Hamilton's generous eulogy of Sir William White's public services and personal character. Perhaps it may be permitted to another contemporary who knew Sir William well during the last years of his life, and was closely associated with a certain portion of his extra-professional activities, to conclude this notice with a word of tribute to his kindly nature and unselfish disposition. He was always ready to promote any cause which appealed to his sympathy, to help any institution which deserved his aid, and his death ten years ago, was mourned by a large circle of friends who appreciated his abilities, and regarded with affection his kindly generous nature.

H. T. W.

---

* Fuller details of Sir William White's association with the Society will be found in the obituary notice in the *Journal*, 7th March, 1913.

OBITUARY.

◆

Sir Henry Kimber, Bt.—Sir Henry Kimber died at his residence in Putney on December 18th, at the age of 90. He had been a member of the Royal Society of Arts for 47 years, having been elected in 1876.

Born in 1834, he was educated at University College, London, and was admitted a solicitor in 1858. He founded the well-known firm of Kimber and Ellis, now Kimbers, Williams and Co., from which he retired in 1890. During his professional career of 40 years he was engaged in many famous cases, prominent among which were the "Balham Mystery" and the scandals in connection with the Grosvenor Hotels Company.

Sir Henry Kimber was a director or chairman of many railways and industrial companies, including, among others, the South Indian Railway, the Pondicherry Railway, the Royal Swedish Railway, the Capital and Counties Bank, the Natal Land and Colonization Company and the Colonist Land and Loan Corporation. He entered Parliament as conservative representative of Wandsworth in 1895, and retained the seat till 1913. He worked hard in the endeavour to correct electoral anomalies by a fair scheme of redistribution, and he rendered much valuable service on Parliamentary committees.

VENEER INDUSTRY OF FINLAND.

The veneer and plywood industry in Finland was founded during the war and has developed rapidly. There are now seven factories, with a total yearly production of about 30,000 tons of veneer. The 50 lathes in operation are being increased to 58.

The best qualities of veneer are used for furniture and ceilings, etc., the poorer qualities being used for the manufacture of packing boxes of various kinds, especially tea chests. About 30 to 40 per cent. of the exports of veneer consist of tea chests.

The exports during 1922 amounted to about 20,000 tons, being about 100 per cent. more than the corresponding figures for the preceding year. The exports have gone almost exclusively to England, small quantities only having been shipped to Belgium and the Netherlands.

It is reported by the United States Consul at Helsingfors that one of the largest veneer factories in Finland has been greatly enlarged of late and has taken up the manufacture of a new veneer called "Tarso," said to be patented in 15 countries. The manufacture of "Tarso" veneer consists of imitating inlaid work and wood mosaic on veneer by means of photography in such a way as to show all original colours, these being burned into the wood. The price of "Tarso" veneer is stated to be only about three times that of common veneer and an unlimited number of copies may be made from a plate. It is expected that "Tarso" will find a good market, especially in the cabinet-making industry.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

January 23.—G. **Albert Smith**, "Cinematography in Natural Colours—further Developments" (with illustrations—scenes from H.R.H. The Prince of Wales's Tour in India).

January 30.—**Sir Richard Arthur Surtees Paget**, Bt., "The History, Development and Commercial Uses of Fused Silica." **Sir Herbert Jackson**, K.B.E., F.R.S., will preside.

February 6.—**Iyemasa Tokugawa**, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

February 13.—H. **Maxwell-Lefroy**, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle." **Sir Aston Webb**, K.C.V.O., C.B., P.R.A., will preside.

February 20.—**Percival James Burgess**, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

February 27.—

March 5.—Major-General Sir Fabian Ware, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries."

March 12.—Alan A. Campbell Swinton, F.R.S., late Chairman of the Council, "Recollections of some Notable Scientific Men." (Illustrated by Photographs.)

March 17.—R. L. Robinson, Member of the Forestry Commission, "The Forests and Timber Supply of North America."

March 24.—Neal Green, "The Fishing Industry and its By-Products."

Dates to be hereafter announced :—

Sir Lynden Macassey, K.B.E., "London Traffic."

Charles S. Myers, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

T. Thorne Baker, "Photography in Industry, Science and Medicine."

Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons at 4.30 o'clock :—

January 4.—Brigadier-General H. A. Young, C.I.E., C.B.E.; late R.A., Director of Ordnance Factories, India, 1917-21, "The Indian Ordnance Factories and Indian Industries." General Sir Edmund Barrow, G.C.B., G.C.S.I., Member of the Council of India, will preside.

January 18.—Colonel H. L. Crosthwait, C.I.E., R.E., retd., late Superintendent, Survey of India, "The Survey of India." Sir Thomas H. Holland, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, will preside.

February 15.—Sir Richard M. Dane, K.C.I.E., Commissioner North India, Salt Revenue, 1898-1907; Foreign Chief Inspector, Salt Revenue, China, 1913-18, "Salt Manufacture in India and China."

May 2.—Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced :—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons at 4.30 o'clock :—

February 5.—F. W. Walker, "The Commercial Future of the Backward Races, with Special Reference to Papua." Sir George R. Le Hunte, G.C.M.G., will preside.

May 27.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Date to be hereafter announced :—

The Hon. T. G. Cochrane, D.S.O., "Empire Oil: The Progress of Sarawak."

CANTOR LECTURES.

Eric Keightley Rideal, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." Three Lectures. January 21, 28; February 4.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25, March 3, 10.

COBB LECTURES.

Monday evenings, at 8 o'clock :—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

DR. MANN JUVENILE LECTURES.

(Special tickets are required for these Lectures.)

Wednesday afternoons, at 3 o'clock :—

Dr. William Arhur Bone, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology. "Fire and Explosions." Two Lectures, January 2, 9. The Lectures will be fully illustrated with experiments.

Mrs. Julia W. Henshaw, F.R.G.S., Croix de Guerre, "Among the Selkirk Mountains of Canada (with ice-axe and camera)." One Lecture. January 16. The Lecture will be fully illustrated with hand-painted lantern slides.

Journal of the Royal Society of Arts.

No. 3,711. VOL. LXXII.

FRIDAY, JANUARY 4, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

NEXT WEEK.

Wednesday, January 9th, at 3 p.m. (Mann Juvenile Lecture.) **Dr. William Arthur Bone**, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology, "Fire and Explosions." (Lecture II.) The lecture will be fully illustrated with experiments.

Special tickets are required for this course and for the Mann Juvenile Lecture by **Mrs. Julia W. Henshaw**, F.R.G.S., Croix de Guerre, entitled "Among the Selkirk Mountains of Canada (with ice-axe and camera)," to be delivered on Wednesday, January 16th, at 3 p.m. A few tickets for both courses are still left, and these will be issued to Fellows who apply for them at once.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

SIR GEORGE BIRDWOOD MEMORIAL LECTURE.

Friday, December 7th, 1923.

Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I., in the Chair.

The Chairman said that it was with very great regret that he had to announce what, he knew, would be a grievous disappointment to the audience, as it was to himself—that the Secretary of State for India was unable to be present to take the Chair. Lord Peel had looked forward very much to presiding that afternoon, and had written him the following letter:—

India Office,
London, S.W.1.
7th December, 1923.

"My dear Sir Charles,

"It is with very keen disappointment that I find myself prevented at the eleventh hour from carrying out my promise to preside at the Sir George Birdwood Memorial Lecture this afternoon. Unfortunately elections are no respecters of ministers, whether members of the Lower or Upper House; and I to my cost have paid the penalty by succumbing to an attack of election sore throat, which makes it quite impossible for me to speak with any pleasure to myself or my hearers. My only course is to submit to this infliction and to treat it patiently with two or three days' rest. I must ask you to express my most sincere apologies to the Royal Society of Arts, to Mr. Digby, the Secretary, and above all to Mr. Foster, to whose lecture I had been looking forward with that keenness of interest which must inspire everyone who knows his record and hopes to hear him speak on a subject which he has made so peculiarly his own. Will you please also express to those who will be attracted by Mr. Foster's name to come to the meeting this afternoon my envy of their good fortune which it is not my privilege to share?

Yours sincerely,
Peel.

In the circumstances it had devolved on himself, as Chairman of the Indian Section of the Society, not to fill Lord Peel's place, because he could not pretend to do that, but to occupy the Chair, and in that capacity he had the great pleasure of introducing Mr. Foster. It was superfluous to do so, because to everyone who was interested in India as she had been, and to a great extent as she is to-day, Mr. Foster's name was thoroughly well known. Everybody knew how Mr. Foster had worked in the India Office, and what valuable work he had done. What everybody did not know was a secret which he had recently learned with surprise, namely, that Mr. Foster's labours in the India Office had extended over a period of more than 40 years. In that time Mr. Foster had acquired an unrivalled knowledge of the activities of the East India Company and of the Administration of India under the Crown, and the results of his researches and studies were embodied in works which now formed a part of every decently equipped library dealing with Indian subjects. In the ordinary course, Mr. Foster would have retired at about the present time, but, happily for India and for students of Indian history, official routine had not been allowed to deprive India of his services, and he now appeared, no longer as Registrar but under the more dignified and appropriate title of Historiographer. They all congratulated Mr. Foster and themselves on the fact that he was staying on to continue his work and that such a high honour had been bestowed upon him.

THE ARCHIVES OF THE HONOURABLE EAST INDIA COMPANY.

By William Foster, C.I.E.,
Historiographer, India Office.

Previous lectures in this series have recalled to our memories Sir George Birdwood's affection for the peoples of India and the services he rendered to that country both in the promotion of its industrial arts and in securing a proper appreciation of Indian artistic skill, alike in painting, sculpture, and architecture. This afternoon it is my privilege to discourse upon another subject to which his many-sided genius paid no small amount of attention, with results that still claim our gratitude.

For the reason of his interest in the history of the relations between India and this country we have not far to look. His connexion with Plymouth, not only as the home of his ancestors but as the scene of his own boyhood, had imbued him with a veneration for the sixteenth and seventeenth century navigators; while the picturesque side of the trade, especially in the early days, appealed strongly to his vivid imagination. Moreover, to say nothing of collaterals, his father, grandfather, and great-grandfather had been, like himself, in the service of that Company which, as he once wrote, was in his eyes "the greatest and most beneficent trading organisation of any age or nation." Intensely patriotic, he gloried in the stirring story of the acquisition of British supremacy over the Indian peninsula; and to him every detail of that story was of interest, and every document relating thereto was sacrosanct.

The earliest sign of his attention to the subject of the Anglo-Indian records was given by an anonymous communication to the *Athenaeum* of 22nd February, 1873, in which he commented sarcastically upon the destruction of documents that took place after the transfer of the records to official custody. Not long afterwards he received, in his capacity of Curator of the Museum, a box which had been lying for some time in the Political Department; and this, on being opened, proved to contain forty parchment documents, including many of the Company's charters. On these Dr. Birdwood (as he then was) submitted in April, 1875, an interesting report, in which he had the assistance of Mr. W. N. Sainsbury, of the Public Record Office. Subsequently he was asked to examine and report upon a large collection of records, chiefly of the seventeenth century, which had never been closely investigated. The main body of the records, from 1702 onwards, had always been well cared for, both at the East India House and at the India Office: but these relics of an earlier time had been comparatively neglected. In November, 1878, Birdwood presented a detailed report, dwelling with enthusiasm upon the great value of the collection, especially in relation to the economic history of India. The report was not made available for general use until 1891; but copies of the official edition were widely circulated, and the interest thus aroused contributed largely to the creation in 1884 of a Registry and Records Department at the India Office, under Mr. F. C. Danvers. The measures thereupon taken to classify and publish the official archives never lacked Birdwood's support and the benefit of his advice; while he himself took no mean share in the work of publication. When in 1886 the first volume of the East India Company's Court Minutes was published at the expense of an American (Mr. Henry Stevens), Birdwood contributed an admirable preface. This led to an offer from Mr. Quaritch to publish another volume of records, to be chosen and edited by Sir George, and the result was the issue in 1893 of *The First Letter Book*. Another example of his interest in the subject is the work entitled *Relics of the Honourable East India Company*, published in 1909. This volume is lying in a prominent position on his desk, in the picture I now show, which represents Birdwood seated in his room at the India Office.

In saying something to-day about the Company's records, I do not propose to weary you with an elaborate account of their classification and contents. That side of the subject has been dealt with in a paper read before this Society by Mr. Danvers in 1890; and, moreover, about five years ago the India Office issued a little handbook intended to guide the student through the labyrinth of archives. I might dwell upon the fact that the India Office collection is the second largest accumulation in England: that in range of subject it approaches the Public Record Office itself: that it provides better material for the history of India than can be found in any Indian record office: that in addition it contains masses of information about other parts of the Empire, such as Ceylon, the Cape, St. Helena, the Straits Settlements, and also about China, Japan, Egypt, Persia and other Asiatic countries. All this, however, is perhaps already known to you; and my aim this afternoon will be to enable you, with the aid of illustrations, to gain some idea of the more important classes of documents, and thereby to understand the value and interest of the historical materials which still await investigation by students.

The first series to which your attention is directed is that known as the Parchment Records, which includes many of the charters granted to the East India Company. Of these the earliest now surviving is that granted by Charles II. on 3rd April, 1661, the last sheet of which is here shown. As will be seen, the document has been sadly misused. Part of the ornamental border has been cut off; and although the arms of the Company (*i.e.*, the arms of the Old Company, 1600-1709) are still at the top of the page, the corresponding drawing at the bottom has been stolen. The seal, too, is missing. This charter is a landmark in the history of the Company, granting, as it did, power to make war or peace with non-Christian nations, to fortify settlements, and to maintain garrisons. Such powers were sought, not with any aggressive aim, but solely to legalize the Company's position. It already possessed fortified settlements at Madras and St. Helena, for which soldiers had to be recruited; while its right to conclude agreements with Asiatic Powers had recently been called in question.

Our next illustration reproduces the first page of a volume containing the subscriptions towards the two million loan which was the condition for the establishment of a new East India Company, under the authority of an Act of Parliament passed in 1698. The subscription list was opened at Mercers' Hall on 14th July, 1698, and Macaulay has described the rush of investors to enter their names. On the page here shown the first entry is one of £10,000, subscribed by the four Lords of the Treasury on behalf of King William III. All four subscribed also on their own behalfs; while among other names we notice those of the Duke of Shrewsbury, the Earl of Portland, the Earl of Montagu, the Earl of Ranelagh, and the Earl of Orford (better known as Admiral Russell, the victor of La Hogue). The seals and signatures underneath are those of seven of the commissioners appointed to superintend the reception of the subscriptions.

As a consequence of the success of this subscription, a royal charter was issued on 5th September, 1698, establishing a new East India Company. It is a sign of the changed circumstances that this charter (of which the first sheet is now shown) is expressly stated to be issued in accordance with an Act of the legislature, whereas previous grants had been made at the will of the sovereign. In the top left hand corner will be noticed a portrait of King William.

One clause in this charter required the Company to put a chaplain on board every vessel of 500 tons or upwards. The result was that, for the next three quarters of a century, the Directors carefully avoided chartering more than 499 tons in any one ship.

Following that charter we have the grant of arms by the College of Heralds to the New Company, dated 13th October, 1698. These arms were adopted by the United Company when the old and new bodies were amalgamated in 1709, and they continued to be used down to 1858. The crest —irreverently nicknamed the "cat and cheese"—was often used separately as a badge of the Company, and it may still be seen on many of the chairs in the India Office.

Another document belonging to the same collection is an original letter from James I. to Shah Abbas of Persia, dated 14th February, 1622, requesting the Shah to favour and protect the English merchants trading in his country. This letter found its way into the possession of the Koninglijk Oudheidkundig Genootschap of Amsterdam; and in 1894 that Society, at the instance of Mr. Danvers, generously presented it to the India Office. It is particularly interesting as a specimen of the royal letters which, in the early part of the seventeenth century, were freely sent to Eastern monarchs at the suit of the East India Company; and, doubtless, the letter which Sir Thomas Roe presented to the Emperor Jahangir at the time of his embassy was similar in appearance to the document on the screen.

Turning to the administrative records, the first section that claims our attention is that of the Court Minutes, of which, with a few exceptions, the India Office possesses a complete series from 1599 to 1858. The first example to be shown is part of the record of the meeting held on 24th September, 1599, to arrange for the despatch of an expedition to the East Indies and to elect representatives to manage the details. The list of those present contains some interesting names. It is headed, as will be seen, by Alderman Sir John Hart, who had been Lord Mayor in 1589-90. He was elected Governor of the Company in 1602, but refused to serve. Then come four more Aldermen, including William Halliday, who was Governor from 1621 until his death in 1624. The next person mentioned is Richard Staper, whose promotion of the journey of Ralph Fitch to India in 1583 is well known; while lower down will be found the name of John Eldred, who was one of Fitch's companions for part of the way on that memorable expedition.

Skipping a period of over sixty years, we come to the time of the Great Fire. Here is the record of the first Court meeting held after that calamity, namely, on 10th September, 1666. Though the East India House escaped the flames, it was for a time in danger, and the books and other objects of value were hurriedly removed to Mile End and Stepney. At this meeting they were ordered to be brought back, and the thanks of the Court were awarded to those who had superintended the removal. A refusal was also given to the request of a haberdasher, whose premises had been burnt and who hoped that the Company would let him have part of the front of their house for a shop.

It would be easy to spend the rest of our time in producing entries of interest from this valuable series; but I must limit myself to one more, and that shall be the record of the vote (on 24th April, 1799) of £10,000 to Lord Nelson, in recognition of his victory at the Battle of the Nile—a victory which shattered Napoleon's dream of making Egypt a stepping stone for the invasion of India. It will be seen that an attempt was made to reduce the grant to £5,000, but in the end the original proposal was carried. The next slide shows Nelson's effusive letter of acknowledgment (written, of course, with his left hand). In it he refers to the fact that in his younger days he had himself served in the East Indies. The original letter, framed, now hangs in the reading-room of the India Office library.

From the Court Minutes we may go to the letters sent by the Directors to their servants in the East. Down to the year 1753 those letters were copied into volumes, now known as the Letter Books. From this series we give two specimens. The first is a page of a letter to Surat in March, 1668, announcing that the King has been pleased to bestow upon the Company the Island of Bombay, and ordering that possession should be taken as soon as possible. Directions are given for "the establishing of a good government," and the factors are enjoined to "incorage the natives that are there and invite others to come thither." The second specimen is part of a letter addressed to Madras on 12th December, 1687. It is generally assumed to have been dictated by Sir Josia Child, who was then Governor, and it contains the oft-quoted passage in which a hope was expressed that the hostilities then being carried on with the Mogul authorities in Bengal would result in laying "the foundation of a large, well-grounded, sure English dominion in India for all time to come"—an expectation that was woefully disappointed by the outcome of the war. The importance attached by the Directors to clear handwriting is well shown by the penmanship of this series and the Court Minutes.

From 1753 onwards the copies kept at the East India House of letters sent to the East were arranged in several series, according to the Presidency to which they were addressed. These comparatively modern documents have not the quaintness of the earlier ones, and I have not thought it necessary to show any of them this afternoon. One special feature (with which it is difficult to deal by means of photography) is that from 1784 onwards they show the red-ink alterations made in the original drafts by the Board of Control—the Government department formed in that year to supervise the Company's administration in all branches save that of commerce.

An interesting example of the conservatism of the Company is the fact that, from the very beginning right down to 1858, the Directors' letters were subscribed "Your loving friends." Sir George Birdwood once quoted this as a proof of the excellent relations that subsisted between the Company and its servants; but I fear that, when it closed (as it often did) a letter of stinging rebuke, it was regarded by the recipients as nothing more than a conventional formula.

From the letters sent to the letters received is an easy transition; and here we have the added interest that in most cases we are dealing with originals, not copies. For the seventeenth century these documents are mostly to be found in one collection, known as the "Original Correspondence." From its riches it is difficult to make a selection; but I now show three specimens. The first is the earliest of the letters now extant. It was written at Bantam (in Java) on 16th December, 1607, to advise the Company of what was happening in that distant factory, and was received in September, 1608. As will be seen, the document has suffered some damage, and parts are difficult to decipher. One of the signatories, Gabriel Towerson, was the chief of the Englishmen put to death by the Dutch in 1623, in what was called the "Massacre of Amboyna." The next slide reproduces a letter from Sir Thomas Roe, whose embassy to the Emperor Jahangir is well known. This epistle, which is in the ambassador's handwriting, was dated at Ajmer on 27th April, 1616, and addressed to the Rev. William Lescke, the chaplain at Surat. In it, alluding to the Mogul Court, Roe says: "I never imagined a prince so famed could live so meanly. All his wealth is no woonder; the Norose [*Nauroz*], at which tyme all is exposed, is a poore May game. Religions infinite, lawes none. In this confusion what can bee expected?" As an accompaniment to this letter, a portrait of Roe may be of interest. It is from the painting in the National Portrait Gallery, which is considered to be a copy of the original portrait by Miereveldt.

The third specimen is part of a letter from the Bengal factors to the Company, dated 30th September, 1689, and signed by Job Charnock (whose name is for ever associated with the founding of Calcutta), Francis Ellis, Jeremiah Peachey, and John Beard. In it the writers reaffirm their conviction that "Chutanuttee" (the future Calcutta) is the most suitable place for the headquarters of the English in Bengal. Ellis succeeded Charnock as Agent at Calcutta; while later on Beard held the same post, with the higher title of President.

The next exhibit is the concluding portion of a letter from Fort St. David, dated 17th October, 1746, announcing that Madras had been captured by the French on the 10th of the preceding month. The letter is signed by the Governor and Council of Fort St. David, which, in consequence of the loss of Madras, had become the seat of government.

By way of counterpoise to this melancholy document, I next show a holograph letter from Lord Clive, written on 18th April, 1757, congratulating the Company upon the capture by his troops of Chandernagore, the headquarters of the French in Bengal. It is a brief, soldierly epistle, which yet conveys something of the force and directness characteristic of that remarkable man. As a pendant I insert here a portrait of Clive, from the painting by Sir Nathaniel Dance, in the National Portrait Gallery.

Turning now to more peaceful subjects, here is a holograph letter from Warren Hastings to the Secretary of State (Lord Rochford), dated 4th December, 1774, expressing his gratification at having been appointed Governor-General, and lamenting the differences that had already arisen between him and his new colleagues from England.

Another great name is recalled by the succeeding slide, which reproduces a letter from Lord Mornington (afterwards the Marquess Wellesley), announcing to the Court of Directors that he had arrived in India and had assumed charge of the post of Governor-General. Only one side of the letter appears in the photograph.

Next comes part of a letter from His Lordship's brother, Sir Arthur Wellesley, the future Duke of Wellington. It was written from No. 11, Harley Street, on 11th April, 1807, and forwarded to the Directors a memorandum correcting certain erroneous statements concerning the battle of Assaye.

After seeing so many documents, it may be a relief if I give three or four slides representing the East India House itself. The first view is of the original building on the site, known as Craven House, owing to its being the property of Sir William Craven and his son, the famous Earl of Craven. This building was rented by the Company in 1648, and purchased about sixty years later. The representation here given is taken, as you will see, from the shopbill of William Overley, a joiner, who is shown in the foreground as occupying a small shop in the front of the House. The next slide shows the same premises, after their reconstruction at the beginning of the reign of George II., though the picture itself was drawn towards the end of the century. The East India House is the long building on the right. The third view is of the House in a still later stage, when it had been rebuilt by Jupp in 1796-9. Here we are looking up Leadenhall Street towards Cornhill. In the distance are the churches of St. Peter and St. Michael. Finally, we have the Directors' Court Room. Conspicuous in this is the Chairman's seat, now used at the India Office by the Secretary of State for India. Some of those present this afternoon will recognise other items of the furniture, particularly the tables and the door, as being now in the India Office Council Room.

We next proceed to consider another great division of the records, namely, the volumes recording the consultations or proceedings of the various administrations in India. From the earliest days the Company insisted upon corporate responsibility among its servants in the East. Every matter of importance had to be debated by the factors on the spot, and records of these consultations, signed by those taking part, had to be sent home for information. As the number of factors increased, it became the practice for only the seniors to meet in consultation, and this assembly hardened into a Council of a fixed number. There is thus an unbroken continuity between the earliest meeting of a few factors at Surat and the present day deliberations of the Viceroy and his Council. The picture on the screen gives the record of a consultation held by the Surat President and his associates on 26th February, 1620, John Bickell, commanding the Fleet, being also present. The list of those attending includes Thomas Kerridge (the then President), Thomas Rastell (President in 1621-25 and 30-31), Giles James, and Edward Heynes (Roe's former secretary).

Passing over a period of 160 years, we come to a page recording the proceedings of the Government of Bengal in the Secret Department on 20th July, 1780. At that meeting the Governor-General (Warren Hastings) handed in a minute, written more than a fortnight earlier, which provoked the famous duel between him and Philip Francis. Of the latter Hastings wrote in his minute: "I judge of his public conduct by my experience of his private, which I have found to be void of truth and honour"; and directly this came to the knowledge of Francis he issued a challenge. As you all know, the result of the meeting was that Francis was wounded, and he went home not long after. It is interesting to speculate what the consequences might have been, had the encounter ended differently.

This seems to be a suitable place to introduce a portrait of Warren Hastings. It is from a painting by Lemuel Abbot, painted about 1796. Hastings himself thought it a good likeness, and distributed replicas among his friends. The photograph here reproduced is from one of these, given by Hastings to David Anderson in 1797.

A present-day subject of controversy is recalled by the next slide, which shows the entry, on the Proceedings of the Government of Bengal, of a letter from Sir Stamford Raffles, dated 13th February, 1819, announcing his occupation of the Island of Singapore, and dwelling upon the importance of the new acquisition. This document is an opportune reminder of the fact that it was to the foresight and energy of one of the East India Company's servants that this notable addition to the Empire was due. It also reminds us that the India Office records are of primary importance for the history of many of the British colonies — a fact which is slowly being recognised.

Besides the records of the East India Company, the India Office archives include the documents of the Government Department known as the India Board or Board of Control, which, as already noted, was established in 1784 to supervise the Company's administration of its possessions in the East. These records consist largely (though not exclusively) of the minutes of the Board and its correspondence with the Directors; and since they only indirectly concern the subject of the present paper, it will perhaps suffice if I exhibit one specimen, namely, part of the record of the first meeting of the Commissioners. This was held on 3rd September, 1784, when His Majesty's commission was read and those present, including, it will be seen, Lord Sydney (Secretary of State), William Pitt, and Henry Dundas, took the required oath to fulfil their duties faithfully and give their best advice and assistance for the good government of the British possessions in the East Indies.

It is often supposed—and not unnaturally—that the India Office archives must contain a large number of documents in Oriental languages—particularly Persian, which was for so long the medium of diplomatic correspondence and the language of the Company's law courts. As a matter of fact, this is not the case. Among the very early records there are some documents in Japanese, which have been copied and published by students from that country, as interesting specimens of the language in its seventeenth century stage. Occasionally, too, one comes across documents in other Oriental languages, in most cases Persian. But this is exceptional; as a rule, the originals were not sent home, for two reasons. In the first place, they might be needed at any time in India for production in case of dispute: in the second, they would be of little or no use in England, where translations would serve all the requirements of the Company. In the latter part of the eighteenth century, however, certain Indian rulers wrote from time to time to the British sovereign; and these letters, which, of course, came in original, may occasionally be met with in the archives of the India Office. Here is a specimen, namely, a letter from Mir Jafar, Nawab of Bengal, to King George III., written apparently about the end of 1764, announcing the removal of Mir Kasim and his own resumption of the *masnad*. The Nawab begs for a reply, undertakes to pay whatever is due from him, and expresses a hope that His Majesty will order the Company's officials to abstain from interfering in the administration of the province.

Next is shown a letter in Malay, from the Sultan of Mindanao (the most southerly of the Philippine Islands) to George III., offering an alliance, offensive and defensive, and promising facilities for British trade in his country. This letter was brought home by Capt. Thomas Forrest, and is mentioned in his work entitled *A Voyage to New Guinea.*

The third slide in this section reproduces one of the original copies of the Treaty of Allahabad, 1765, signed on the one hand by Lord Clive and General Carnac, and on the other by Shuja-uddaula, Nawab of Oudh. At the top is the seal of the Great Mogul. The witnesses on the English side are Edmund Maskelyne (Clive's brother-in-law), Archibald Swinton, and George Vansittart (who was Persian Translator). This document, framed, now hangs in the reading-room of the India Office Library.

We go next to the large and important collection of Marine Records. This consists largely of the logs and ledgers of the Company's vessels, extending from 1605 to 1856, with, in addition, over 900 volumes of miscellaneous records relating to the subject. During the seventeenth century the logs were kept in ordinary books and in narrative form. Here is a specimen—the first page of Captain Saris's account of his pioneer voyage to Japan in 1611-13, with its pious invocation and heading, followed by a matter of fact recital of the course of events day by day. The greater part of this journal was printed in 1900 by the Hakluyt Society, under the editorship of Sir Ernest Satow. Early in the eighteenth century the form of the log was systematized, and specially printed books were issued for the purpose. As a specimen of these may be given part of a page from the log of the *Earl Camden,* containing Commodore Dance's account of the action between his merchant fleet and a squadron of French men-of-war off Pulo Aor in February, 1804. The record is amusingly laconic: "At noon, perceiving the enemy bear up to attack our rear, made the signal to the headmost ships and tacked towards them. At 12.10 the enemy opened their fire on the *Royal George, Ganges,* and ourselves, which we all returned; when about one the enemy hauled their wind to the E.N.E. Made sail after them, as did the fleet." This fight, which saved from capture a fleet of immense value, made a great sensation in England, and brought Dance a knighthood and a pension, besides presents of money to a considerable amount.

Ships' logs, we know, often supply the only records available of births, deaths, and even marriages, occurring during the course of a voyage; and this brings us to another interesting section of the records, namely, the registers of such events on land. The India Office possesses a large collection of returns giving baptisms, marriages, and burials of Europeans in the East Indies. The Madras series commences in 1698, the Bombay in 1709, and the Bengal in 1713; while there are also returns for St. Helena, Prince of Wales Island, Macao (in China), and Fort Marlborough (Java). Returns are still received regularly from India, and certificates from them are constantly in request, since, in the absence of any compulsory system of notification of births and deaths, these ecclesiastical registrations are generally the only proofs available for legal purposes. Of the returns of baptisms, a specimen is here presented, which records the baptism of Sir George Birdwood at Belgaum on 29th January, 1833. It will be noticed that the date of birth is given, and that to-morrow will be its ninety-first anniversary. For an example of the returns of weddings, I have chosen the page containing the entry of the marriage of Warren Hastings with the divorced wife of Baron Imhoff at Calcutta on 8th August, 1777. It will be seen that the bride gave her maiden name. Dr. Busteed says that the wedding took place "most probably very quietly and in a private house." On the same page, at the top, is the record of the marriage of George Francis Grand to Mademoiselle Werlée, which was solemnized in the house of Thomas Motte. The Rev. William Johnson officiated, as he did at Hastings's wedding. Mrs. Grand's speedy entanglement with Philip Francis, and her marriage years afterwards to Prince Talleyrand, are too well known to need more than a passing allusion.

Owing to the fact that in early days the services of a clergyman were seldom available except in the presidency towns, baptisms and marriages were often celebrated by laymen holding official positions, whether civil or military. The practice was analogous to that which still obtains of British Consuls in foreign countries conducting marriages between British subjects. The validity of such non-ecclesiastical marriages in India was sometimes questioned, but it was generally held that the practice was covered by the powers granted to the Company. It gradually came to an end when the ecclesiastical establishments were increased in the early part of the nineteenth century.

As regards burials, I reproduce a page from the St. Helena returns, recording the interment on 9th May, 1821, of "Napoleon Buonaparte, late Emperor of France." The corresponding record of his death in the St. Helena Consultations is: "Saturday, the 5th, died General Napoleon Buonaparte." The spelling of the surname in both instances recalls the fact that the Allied Powers, to emphasize Napoleon's Corsican origin, insisted on retaining the original spelling, though he himself had long ago adopted a form that looked more French.

For purposes of family history the papers relating to appointments in the Company's services are often of great importance. An essential preliminary was to obtain a nomination from a Director; but the candidate was then required to make a formal application to the Court, accompanied by evidence of the date of birth and other particulars. Here is a specimen of such an application, namely, that submitted by Warren Hastings in 1749 for a writership. With this were forwarded a copy of the record of his baptism and a certificate that he had "gone through a regular course of merchants' accounts" under the supervision of Mr. Thomas Smith, of Christ's Hospital. Hastings's school—Westminster—of course did not profess to instruct its pupils in such mysteries; but it may perhaps take credit for the excellent penmanship of the application.

In the parallel series of applications for military appointments we may select the one sent in by the late Lord Roberts, in 1849. This is on a printed form, only the upper part of which has been reproduced. On the lower part of the page is the nomination, which was made by Major-General Caulfield, at the instance of the candidate's father, General Abraham Roberts. By that date, of course, the application was really for admission to the Company's Military Seminary at Addiscombe.

Of all the officials of the Company's home service the best known is Charles Lamb, a sketch portrait of whom, drawn and etched by his friend and fellow clerk, James Brook Pulham, is next shown. Lamb wrote of it: "'Tis a little sixpenny thing, too like by half, in which the draughtsman has done his best to avoid flattery." The costume was, no doubt, that in which Lamb performed his daily duties at the East India House. The "massy tomes" in which he day by day recorded transactions in tea, cotton goods, and indigo—"more MSS. in folio," he said, "than ever Aquinas wrote, and full as useful"—were long since sent to the papermaker with the Company's other commercial records; and to-day we have little at the India Office directly connected with Lamb. His portrait by Henry Meyer—by many considered to be the best extant—hangs in the room of the Under Secretary of State; the Accountant-General's department cherishes a book of interest tables in which he inserted three mock reviews, alluding to the great interest of the work and the way in which that interest "rises to the end;" but all that the Record Department can show (besides the references to him in the Court Minutes) is four security bonds bearing his signature. The Directors were men of business, and every clerk who had to deal with money or keep accounts was required to furnish security; while, if a surety died, a fresh bond had to be executed. Here is a facsimile of the first bond signed by Lamb, in which he and his securities agreed to forfeit £500 of lawful money of Great Britain, in the event of any delinquency on his part. His two sureties on this occasion were his father, John Lamb, and Peter Peirson, of whom he gave a sketch in his essay on the Old Benchers of the Inner Temple.

Our last slide shows the earliest known marine insurance policy, dated in 1657 and now preserved among the Java Records at the India Office. The policy is for the sum of £400, insured on the return cargo of the *Three Brothers*, which had sailed two years previously on a voyage to Bantam and Macassar. The document is of great importance in the history of marine insurance, and it is interesting to note that the main provisions are identical with those contained in a Lloyd's policy of the present day. Until a couple of years ago it was believed that a policy of 1681, preserved at Lloyd's, was the oldest in existence, and the discovery that the India Office possessed a much earlier one aroused considerable interest in marine insurance circles in London, Liverpool and New York. We have, therefore, in this document at once an instance of the richness of the India Office records, and a suggestion that still further discoveries will be made whenever this vast mass of documents is thoroughly explored.

In conclusion, I may point out that, although this afternoon the illustrations chosen have been those considered likely to interest an English audience, the archives of the India Office, and the related collections in India, are as important for Indian as for British history. For three centuries the two countries have been acting and reacting upon each other, to their mutual benefit, and present-day India is largely the outcome of those relations. The study of the steps by which the position of to-day has been reached is of interest alike to India and to Britain, and it is a task to which the scholars of both countries can contribute. This fact is now fully recognised by Indian historians, and the British-Indian archives are being increasingly utilised by them, as well as by students of our own race. I am confident that Sir George Birdwood, whose affection embraced alike the land of his birth and the land of his fathers, would have asked no better reward for his labours upon the archives of the Honourable East India Company than that they should in the manner indicated form a fresh and durable link between the two countries.

DISCUSSION.

THE CHAIRMAN (Sir Charles S. Bayley), in moving a very hearty vote of thanks to Mr. Foster for his most interesting and valuable lecture, regretted that it was not in his power to do so in the more fitting and eloquent language which Lord Peel would certainly have employed. It had been his privilege to listen to all of the five lectures which had been delivered since the Royal Society of Arts had resolved to found an annual lecture in memory of the late Sir George Birdwood. On each occasion care had been taken to ensure that the lecture should deal with a subject in which Sir George Birdwood had been interested, and this had been no difficult task for, as all knew, Sir George loved India and everything connected with it, and there were few Indian subjects which he had not studied. Many Anglo-Indians (the speaker used the word in its old sense) could have said, and many could still say, with truth "*Anglo-Indianus sum, indici nihil a me alienum puto,*" but none could ever have said it with greater truth or with a fuller meaning than Sir George Birdwood. Neither had it been difficult to find worthy lecturers. Sir Valentine Chirol, Sir Edward Grigg, Sir Thomas Arnold, and Sir John Marshall had all dealt in a masterly way with their very varied subjects, and the Royal Society of Arts and the public owed them a very real debt of gratitude. All would, however, agree that the subject of Mr. Foster's discourse was one of which Sir George Birdwood would have heartily approved and that he would equally heartily have commended the choice of Mr. Foster to handle it. Mr. Foster had described Sir George Birdwood's successful efforts to prevent the destruction of the East India Company's records, and to secure their proper classification and investigation. In this work Mr. Foster had done most valuable service, and he had that day delivered a discourse which showed how worthy he was of a place on the honoured roll of Birdwood Memorial Lecturers. He had also earned the gratitude of his hearers not only by telling them about the treasures of the Record Room but by showing what many of the most interesting were like. The records themselves were often very human and it was interesting to be told that in anticipation of Inchcape Commissions, axes, and things of that sort, the Directors of the East India Company had had a real regard for economy which had led them to use smaller ships rather than incur the charge of carrying a chaplain. He could not help wondering, as Mr. Foster had been telling them about that, whether there had not perhaps been a little touch of that superstition at work which had obtained amongst sailors until recently, and which possibly still obtained, namely, that the presence on board ship of a "sky pilot" was not conducive to safety. He remembered an instance of that many years ago. He had started from India, and the morning after sailing was beautifully fine. He had made some remark about it to the quartermaster, who had replied with great gravity "Yes, it is fine, but we have too many parsons on board." He had not thought about that remark again until the ship got in the Bay, where they had the most atrocious weather and had to lay to for two nights. In the midst of the storm he came across the quartermaster, who in a most solemn tone of voice said "I told you I mistrusted them parsons." He just wondered whether that same feeling, unjustifiable though it was, had obtained in those remote days.

One of the most interesting slides to him had been that of the letter from Lord Clive and the picture of Lord Clive. The pride of the speaker's family in its connexion with Clive had always been very great. Lord Clive's father, Mr. Richard Clive, had married a Miss Gaskell, whose sister was the wife of his (the speaker's) great-grandfather, and for some reason or other Robert Clive had been sent when a boy of about eight to live with his Bayley relatives in Manchester and had remained there till shortly before he went out to India. Sir Steuart Bayley possessed a letter written by Mr. Daniel Bayley to Mr. Richard Clive, which read as follows:—

"Respected and dear Sir.......... I hope I have made a little for the conquest over Bob, and that he regards me in some degree as well as his aunt Bay. He has just had a fine suit of new clothes, and promises by his reformation to deserve them. I am satisfied that his fighting (to which he is out of measure addicted) gives his temper a fierceness and imperiousness that he flies out upon every trifling occasion. For this reason I do what I can to suppress the hero that I may help forward the more valuable qualities of meekness, benevolence and patience. I assure you, Sir, it is a matter of concern to us as it is of importance to himself that he may be a good and virtuous man, to which no care of ours shall be wanting. I am, with all respect, your most obliged friend and servant, Daniel Bayley."

Mr. Bayley's sentiments were laudable and natural to a man of his peaceful disposition, but no Englishman, and indeed no Indian who had his country's true welfare at heart, could fail to rejoice that Providence in its wisdom had willed otherwise, and had decreed that Clive's "fierceness and imperiousness" had turned into bravery and courage and readiness to fight for the right, which had been the foundation of the Indian Empire, and had redounded to the welfare of England, India, and of the world.

SIR EDWARD M. COOK, C.S.I., C.I.E., I.C.S., in seconding the motion, said he felt it was in some mesaure a presumption on his part to do so, partly because he was still a school boy when Mr. Foster had already made his reputation as an authority on Indian history, and partly because he belonged to a generation of Indian officials that had, he feared, fallen very far behind their predecessors in the matter of the study of Oriental languages and history. Whether that was entirely their fault or not, he could not say. They could only hope that succeeding generations of officials, having probably less heavy responsibilities, would be able to repair the omissions of the present generation. Whatever might might be the omissions of the present generation of Indian officials in that matter, he could assure the audience that those in India had at any rate a very keen appreciation of the work that students such as Mr. Foster were carrying on and he knew from his own experience the enormous help that students of both races who came to this country to prosecute their studies always received from Mr. Foster and his Department.

The motion was carried unanimously and the meeting terminated.

NOTES ON BOOKS.

THE TOMB OF TUT-ANKH-AMEN. By Howard Carter and A. C. Mace. Vol. 1. London: Cassell and Company, Ltd. 31*s*. 6*d*. net.

Eighteen months ago how many people in this country or any where else knew the name of Tut-Ankh-Amen? The number of those who can pronounce it correctly may still be strictly limited, but the startling discovery of his Tomb, revealing a wonderful wealth of artistic treasures well over three thousand years old, struck the imagination even of the man in the street, and made the name of the Egyptian King as familiar as that of Georges Carpentier or the Derby winner. Day after day *The Times* devoted columns to the description of the treasures which the tomb was yielding up, and whole pages to photographs of them. Probably no antiquarian discovery has ever made such a popular stir as that of the late Earl of Carnarvon and Mr. Howard Carter.

The story of the find, then, is still fresh in one's memory; but it is satisfactory to have it set down in permanent book form by one of the chief actors in the drama. The present volume is the first. It opens with an account of Tut-Ankh-Amen and his Queen, and proceeds, after a general description of the Valley of the Tombs, to tell of the great find, the preliminary investigations, the appearance of the Ante-Chamber, the work in the laboratory, and the opening of the inner-sealed doorway. The work of investigating the contents of the innermost chamber is at the present moment proceeding, and will probably occupy the whole of this season, if not longer. It is hoped that further and still more interesting objects will be found here, and their description will form the subject of Volume II. This will naturally be more of a scientific record than the first volume, which is written in a somewhat popular style.

An introduction is contributed by Lady Burghclere who gives a very charming biographical account of her brother, the late Earl of Carnarvon. A great sportsman, in love with travel and advenventure, it would seem that his tastes were turned towards Egyptology by a serious motor accident which made it impossible for him to follow the very strenuous pursuits in which he had formerly delighted.

A word of praise is due to the publishers for the general get-up of the book. Printing and paper are excellent, and the numerous illustrations are admirably reproduced. Very many of these will be familiar to readers of the book, as they have already been published in many newspapers, but naturally the reproductions in the book are very different from those which appeared in daily and weekly journals.

SOURCES OF SUPPLY OF MANGROVE BARK.

Mangrove bark constitutes one of the world's most important tannin assets because of its great abundance, wide distribution, rapid growth, and comparatively low cost. With a constantly growing market for leather, and a consequent need for ready supplies of tannin, there seems no reason to doubt an early awakening to the economic possibilities of the vast jungles of mangrove that await development along the tropical foreshores of the Eastern and Western Hemispheres. A greater exploitation than hitherto of this most valuable source of tannin, together with the development of new regions of production, would afford effective relief in future demands for tannin.

The following particulars regarding sources of supply of mangrove bark and the manufacture of extract in the principal countries producing the bark has been collated and published by the Research Division of the United States Department of Commerce :—

The mangrove extract of commerce is obtained from the barks of trees belonging to the family Rhizophoraceæ. Of these, the one special to the American Tropics is the Rhizophora mangle, popularly known as red mangle, while several species abound in the eastern Tropics, where the areas under mangrove are far more extensive. All parts of the mangrove tree, but more especially the bark and leaves, contain tannin. The percentage of tannin in the bark ranges from 5 to 48 per cent., the content increasing with the size and age of the tree ; the average of commercial grades is about 35 per cent. If the bark is exposed to moisture after collection, a considerable loss in tannin is sustained, hence the necessity for drying under cover during the rainy season. When dried the bark is roughly broken into small pieces and placed in bags or packed in small bales, sometimes under pressure, for export.

The mangrove extends as far north and south as the twenty-ninth parallel. It forms a dense growth in patches on the low coasts of all tropical islands. In the United States it occurs along the shores of southern Florida, at the mouth of the Mississippi River, and on the coast of Texas. The low coast marshes of Porto Rico produce abundant supplies of mangrove, but, while used locally for both its wood and its bark, the industry has not yet reached an export basis. Mangrove barks constitute the greatest single source of tannin in the Philippines. Analyses prove Philippine barks as rich in tannin content as those used in the cutch factories of Borneo ; in fact, the same species of mangrove are common to both regions. Notwithstanding the abundance of mangrove in the Philippines, there are no cutch factories, although the swamp area of one bay in Mindanao covers 25,000 hectares, which, estimating 25 tons of bark to the hectare, would yield a total of 625,000 tons of bark. With a 20-year rotation this should be sufficient to supply a large factory indefinitely. Foreign markets for the bark have not been developed.

Prior to the war Germany was active in the exploitation of mangrove bark as a tanning agent. Its main source of supply was East Africa, whose barks seem to be richer in tannin than those of the East Indies. In the former German protectorate the bark was most carefully stripped from the living tree (stripped trees are said to renew their bark in four to six months) under the supervision of the forest department and prepared for export. The export of bark containing less than 45 per cent. of tannin was prohibited.

Madagascar exported 21,938 metric tons of mangrove bark in 1913, the greater proportion of which was taken by Germany. In 1917 its exports totalled only 3,410 tons. This decrease was due largely to lack of transportation facilities. Postwar exports, however, have not yet reached the 1913 level. While West Africa has extensive mangrove swamps, no serious attempt at bark collection has yet been made, except in British West Africa, where the industry is well established. Some years ago bark collection was started in Senegal by a French company, which allowed the trees to be cut down without making provisions for replanting, with the result that rapid erosion of the foreshore took place. The Government prohibited further exploitation by that company. Stocks of mangrove bark in Burma were practically exhausted in 1919. The problem of working important areas of mangroves in the Andaman Islands is receiving the serious consideration of the authorities.

The manufacture of extract in the principal countries producing mangrove bark has not been as effectively developed as that of quebracho extract in Argentina and Paraguay. If, however, the industry could be promoted in those countries possessing abundant supplies of mangrove, not only the poorer grades of bark could be utilized but also the leaves, which contain considerable tannin. The leaves are rarely exported, owing to deterioration during transportation. To avoid certain unfavourable chemical changes, which the bark undergoes within 48 hours after cutting, it is considered essential to work it up as soon as possible. For this reason the factory should be located in or near the mangrove area. It requires 4 to 6 tons of bark to produce 2 or 2½ tons of cutch. The elimination of waste, greater convenience for shipment, and saving in transportation costs should make for further expansion in this industry.

Mangrove extract is also called mangrove cutch, because of a similarity of properties to the cutch derived from the Acacia catechu of India and Burma. A constant supply of the latter could not be relied on, and when the mangrove product came into the market it superseded the Indian cutch to such an extent that the term is now mainly applied to mangrove extract.

In Dutch and British Borneo the manufacture of extract has become an industry of great importance. The principal factories are located at Pontianak, Rejang, Brunei, Kudat, and Sandakan. The latter two are under Scotch control. In 1919 the Netherlands Indies exported 3,546 metric tons of mangrove cutch, against 805 tons in 1918. In 1920 and 1921 the exports fell to 1,598 and 830 tons respectively. The bulk of these exports was the output of the Pontianak factory.

Exports of mangrove cutch from the Straits Settlements aggregated 2,481 tons in 1920, an increase of only 106 tons over 1919. The figures for 1921, however, showed a marked increase over the two previous years, amounting to 3,602 metric tons. Straits Settlements exports are largely re-exports having their origin in Borneo.

The extraction of tannin from mangrove bark is a well organised industry in East Africa. The interest which that region takes in its expansion is manifested in two recent concessions granted for the exploitation of the bark in which it was obligatory on the concessionaires to inaugurate tannin extract factories within certain specified periods of time.

Mangrove extract is imported in large blocks of a reddish brown colour, and has a tannin content ranging from 48 to 72 per cent. according to country of origin. The higher grades come from East Africa and Borneo. Used alone this extract yields a good, pliant, workable leather, but of undesirable colour. To modify this objection German tanners blend it with myrabolans, valonia, sumac and similar materials; and British tanners with pine, oak and mimosa barks. In France the favourite blend is Mangrove bark 30 per cent., hemlock bark 40 per cent., oak bark 20 per cent., and mimosa bark 10 per cent. The French blend yields a superior grade of leather, with an excellent colour for general use.

GENERAL NOTES.

Chinese Cotton Mills.—The Chinese Government Bureau of Economic Information has published a sheet of tabulated information respecting cotton mills in China. One of its most important features is the column dealing with the motive power employed. Of the 112 Mills in the list, 37 use electricity either wholly or in part, the remainder being apparently provided with steam plant. Practically all the establishments in Shanghai and Woosung—numbering 24—are electrified, and it will thus be seen that the opportunities for trade in this direction lie mainly in other parts of the Republic. Five British-owned mills are listed. These are all in Shanghai, but the motive power employed is not stated. Information in this respect is also lacking in the cases of 32 Japanese owned factories, mainly in Shanghai and Tsingtau. Apart from these, however, there is a number of establishments with from 3,000 to 90,000 spindles—average about 20,000 in which steam power is still employed.

Cotton in Spain.—Spain is growing more and more cotton in the southern provinces in order to counteract the importation of cotton from America, and, according to the *Indian Textile Journal*, the industry is changing from a purely home industry to an export industry, with all the possibilities of indefinite expansion implied in this change. The industry, located almost entirely in Catalonia—which is the most promising hydro-electric centre in Spain—employs at present over 100,000 workers, and exports considerable quantities of the coarser types of cotton goods to the Spanish colonies and South America. Hydro-electric power on a large scale is being introduced and this will undoubtedly lead to the introduction of electrical driving into the cotton mills, and open thereby a new market of very great importance in the future.

Successful Treatment of Canadian Tar Sands.—It is claimed that methods have been perfected by which commercial products can be obtained from the Athabaska tar sands found in the Province of Alberta, Canada. According to *Commerce Reports*, a plant has been erected at Waterways, on the Great Western Railway, where experiments have been successfully conducted. Two processes are said to have been developed, one for the separating of oils, and the other for extracting asphalt. The crude oil obtained by the first method is of 19.3 Baumé gravity, while the asphalt extracted gives a large yield of the merchantable product, ranging from 15 to 25 per cent. of the raw sand. Owing to the small percentage of the lighter constituents and the presence of sulphur, the crude oil is not the most satisfactory for producing gasoline or kerosene, but the lubricating oil stands an extra low cold test, and is an excellent product for use in cold climates.

Macedonian Opium.—In his report on the Industrial and Economic Situation in Greece, Mr. R. F. Duke, Commercial Secretary at the British

Legation in Athens, calls attention to the fact that the quality of Macedonian opium is excellent on account of the superior dexterity of the labourers engaged in its collection. In making incisions in the poppy head, especial care is taken to avoid cutting beyond the latex into the debris of the pericarp. As a result the Macedonian opium has a fine, light and delicate paste and is remarkably rich in morphine, 15 to 20 per cent. being registered. Anatolian opium usually carries from 9 to 14 per cent. of morphine. The producing districts in Macedonia are :—Veles, Cavalar, Koumano, Istip, Radovitch, Perleps, Strumista in Serbia, 84 per cent. Petrich in Bulgaria, 8 per cent. Kilkis, Serres, Langada in Greece, 8 per cent. The opium crop in 1922 yielded about 500 cases of 150 lbs., whilst an average crop yields 1,000 cases. The countries to which opium is exported are principally the United States of America, Germany and France.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

JANUARY 23.—G. ALBERT SMITH, "Cinematography in Natural Colours—further Developments" (with illustrations—scenes from H.R.H. The Prince of Wales's Tour in India).

JANUARY 30.—SIR RICHARD ARTHUR SURTEES PAGET, Bt., "The History, Development and Commercial Uses of Fused Silica." SIR HERBERT JACKSON, K.B.E., F.R.S., will preside.

FEBRUARY 6.—IYEMASA TOKUGAWA, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

FEBRUARY 13.—H. MAXWELL-LEFROY, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., will preside.

FEBRUARY 20.—PERCIVAL JAMES BURGESS, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

FEBRUARY 27.—

MARCH 5.—MAJOR-GENERAL SIR FABIAN WARE, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries."

MARCH 12.—ALAN A. CAMPBELL SWINTON, F.R.S., late Chairman of the Council, "Recollections of some Notable Scientific Men." (Illustrated by Photographs.)

MARCH 17.—R. L. ROBINSON, Member of the Forestry Commission, "The Forests and Timber Supply of North America." LORD LOVAT, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., will preside.

MARCH 24.—NEAL GREEN, "The Fishing Industry and its By-Products."

Dates to be hereafter announced :—

SIR LYNDEN MACASSEY, K.B.E., "London Traffic."

CHARLES S. MYERS, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MRS. ARTHUR MCGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons at 4.30 o'clock :—

JANUARY 18.—COLONEL H. L. CROSTHWAIT, C.I.E., R.E., retd., late Superintendent, Survey of India, "The Survey of India." Sir THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, will preside.

FEBRUARY 15.—SIR RICHARD M. DANE, K.C.I.E., Commissioner North India, Salt Revenue, 1898-1907; Foreign Chief Inspector, Salt Revenue, China, 1913-18, "Salt Manufacture in India and China."

MAY 2.—JOCELYN F. THORPE, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced :—

BHUPENDRA NATH BASU, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons at 4.30 o'clock :—

FEBRUARY 5.—F. W. WALKER, "The Commercial Future of the Backward Races, with Special Reference to Papua." SIR GEORGE R. LE HUNTE, G.C.M.G., will preside.

MAY 27.—C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Date to be hereafter announced :—

THE HON. T. G. COCHRANE, D.S.O., "Empire Oil: The Progress of Sarawak."

CANTOR LECTURES.

ERIC KEIGHTLEY RIDEAL, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." Three Lectures. January 21, 28; February 4.

EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25, March 3, 10.

COBB LECTURES.

Monday evenings, at 8 o'clock :—

DR. T. SLATER PRICE, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

DR. MANN JUVENILE LECTURES.

(Special tickets are required for these Lectures.)

Wednesday afternoons, at 3 o'clock :—

DR. WILLIAM ARHUR BONE, F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology. "Fire and Explosions." Two Lectures, January 2, 9. The Lectures will be fully illustrated with experiments.

MRS. JULIA W. HENSHAW, F.R.G.S., Croix de Guerre, "Among the Selkirk Mountains of Canada (with ice-axe and camera)." One Lecture. January 16. The Lecture will be fully illustrated with hand-painted lantern slides.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, JANUARY 7..Chemical Industry, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m.

Surveyors' Institution, 12, Great George Street, S.W., 8 p.m.

Victoria Institute, Central Building, Westminster, S.W., 4.30 p.m. Rev. M. G. Kyle, "The Problem of the Pentateuch from the Standpoint of the Archæologist."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal Meeting.) Mr. J. W. Beauchamp, "Troubles Experienced with Domestic Electric Appliances."

Transport, Institute of, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C., 5.30 p.m. Mr. E. M. Lewis, "Inland Waterways"

TUESDAY, JANUARY 8..Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. 1. Mr. J. Kewley, "The Crude Oil of Sarawak." 2. Dr. A. E. Dunstan, "The Crude Oil of Maidān-i-Naftan."

Transport, Institute of, at the Institute of Electrical Engineers, Savoy Place, Victoria Embankment, W.C., 5.30 p.m. (Graduate Section.) Mr. W. C. Collins, "The Organisation of a Terminal Station."

Child Study Society, University College, Gower Street, W.C., 5 p.m. Conference of Educational Association. Miss Elsie Fogerty, "The Diploma in Dramatic Art."

Metals, Institute of (Local Sections), Chamber of Commerce, New Street, Birmingham, 7 p.m. Mr. O. Smalley, "Nickel Brasses." (N.E. Coast Section), Armstrong College, Newcastle-on-Tyne, 7.30 p.m. Mr. H. M. Duncan, "The Action of Molton Brass on Nickel Steel."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Mr. R. Williams, "More Milestones of African Civilisation and some Problems."

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

Mechanical Engineers, Institution of (South Wales Branch), Chamber of Commerce, Swansea, 6 p.m. Sir James H. R. Kernnel "Modern Developments in Steam Raising."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. R. G. Reid, "Modern Refrigerating Machines."

Royal Institution, Albemarle Street, W., 3 p.m. (Juvenile Lecture.) Prof. Sir W. Bragg, "Concerning the Nature of Things." (Lecture VI.)

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Mr. de Barri Crawshay, 1. "Eoliths found *in situ* at South Ash." 2. "Azilian-Tardenoisian Flint Industry in Mesopotamia (*Exhibit*)."

WEDNESDAY, JANUARY 9..Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., 6.30 p.m.

Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. 1. Prof. S. H. Reynolds and Dr. E. Greenly, "The Geological Structure of the Clevedon-Portishead Area (Somerset)." 2. Dr. F. S. Wallis, "The Avonian of the Tyrherington-Tortworth-Wickwar Ridge (Gloucestershire).." 3. Miss A. E. Bamber, "The Avonian of the Western Mendips, from the Cheddar-Valley Railway to the Sea, West of Brean Down."

THURSDAY, JANUARY 10..Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Dr. Aichison and Mr. North, "Materials from the Aeronautical Ploint of View."

Metals, Institute of, at the Institute of Marine Engineers, 85, The Minories, E., 8 p.m. Mr. W. T. Griffiths, "X-Rays and Metallurgy."

Mechanical Engineers, Institution of (Local Branch), Royal Technical College, Glasgow, 7.30 p.m. Prof. J. Muir, "Radiation and Atomic Structure."

Linnean Society, Burlington House, Piccadilly, W., 5 p.m. 1. Mr. A. J. Wilmott, "Some further additions to the British Flora." 2. Mrs. Henshaw, "Plant Life in British Columbia" (lantern slides). 3. Mr. R. H. Burne, "Exhibition of Specimens of the Carotid Arteries of *Lamna* and other Sharks."

Historical Society, 22, Russell Square, W.C., 5 p.m. Mdme J. Lubimenko, "The Anglo-Dutch Commercial Struggle in the 17th Century."

British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. T. Peters, "Italy."

FRIDAY, JANUARY 11..London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Sir Theodore Chambers, "Satellite Towns."

Malacological Society, at the Linnean Society, Burlington House, Piccadilly, W., 8 p.m.

Astronomical Society, Burlington House, Piccadilly, W. 5 p.m.

Timber Trade Lectures, London Chamber of Commerce, Oxford Court, Cannon Street, E.C. Mr. F. Tiffany, "Principles and Ethics of Business."

Metals, Institute of, at the Albany Hotel, Fargate, Sheffield, 7.45 p.m. (Conjoint Meeting with the Institute of British Foundrymen.) Mr. F. H. Hurren, "Influence of Casting Temperature on the Physical Properties of Metals."

Journal of the Royal Society of Arts.

No. 3,712. VOL. LXXII.

FRIDAY, JANUARY 11, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

FUND FOR PURCHASING AND RENOVATING THE SOCIETY'S HOUSE.

NINTH LIST.*

	£	s.	d.
Amount previously acknowledged	43,033	17	4
The Gas Light & Coke Co. ..	200	0	0
George Percival Baker, Esq...	10	0	0
Professor John Uri Lloyd, Ph.D., LL.D.	8	2	0
Harry Houlton Vivian, Esq., J.P.	5	5	0
Rajah Bahadur Naba Kishore Chandra Singh	5	0	0
The late Brigadier-General A. C. Bailward (second donation)	3	0	0
Denis Ripley Broadbent, Esq., A.M.I.E.E., A.M.I.M.E. (second donation) ..	2	2	0
Inayatullah Khan, Esq., M.A.	2	0	0
Francis Wright, Esq. ..	2	0	0
George Andrew Matzinger, Esq.	1	1	0
Samuel Athim, Esq., Assoc. M.Inst.C.E.	1	0	0
Rev. E. O'Neill		10	6
	£43,273	17	10

The above list includes all subscriptions received up to January 1st. Further lists will be published in the *Journal* from time to time.

Fellows of the Society are reminded that the amount aimed at by the Council is £50,000, which will cover the cost of renovating and decorating the House.

---

*The eight former lists were published in the *Journals* of December 2nd, 1921, January 13th, February 24th, May 5th, July 14th, and November 17th, 1922, and February 9th, and July 20th, 1923.

NOTICES.

NEXT WEEK.

Wednesday, January 16th, at 3 p.m. (Mann Juvenile Lecture.) **Mrs. Julia W. Henshaw**, F.R.G.S., Croix de Guerre, "Among the Selkirk Mountains of Canada (with ice-axe and camera)."

A few tickets for this lecture are still left, and these will be issued to Fellows who apply for them at once.

INDIAN SECTION.

Friday, January 4th, 1923; General Sir Edmund Barrow, G.C.B., G.C.S.I., Member of the Council of India, in the Chair.

A paper on "The Indian Ordnance Factories and Indian Industries" was read by Brigadier-General H. A. Young, C.I.E., C.B.E., late R.A., Director of Ordnance Factories, India, 1917-21.

The paper and discussion will be published in a subsequent number of the *Journal.*

BINDING COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their annual volumes of the *Journal*, cloth covers can be supplied, post free, for 2*s.* each, on application to the Secretary.

MANN JUVENILE LECTURE.

The third series of Juvenile Lectures, under the Dr. Mann Trust, was commenced on Wednesday afternoon, January 2nd, by Professor William Arthur Bone, F.R.S., the subject being "Fire and Explosions." The chair was taken by Mr. Alan A. Campbell Swinton, F.R.S., a Vice-President of the Society.

Professor Bone, in his opening remarks related the story of the Norse God, Balder the Beautiful, who, after being, as the gods thought, rendered invulnerable, was slain by Hoder by means of a dart made of mistletoe, the only thing in creation which had not taken an oath to do him no harm. He referred to the veneration of our remote ancestors for the oak, by means of which they kindled a fire, and for the mistletoe which they regarded as the seed of fire and the source of life and vitality. He traced the association of this story with the present -day custom of cutting mistletoe and burning the yule log at Christmastide. Fire had always been surrounded by mystery from the very earliest times, and even in Shakespeare's day, he said, it was considered one of the mysterious elements of which the world was composed.

The lecturer then dealt with the researches and discoveries of Jean Rey (1630) relating to the calcination of metals; of Robert Boyle, the father of modern chemistry, and inventor of what we now know as the air pump; of Robert Hooke, the inventor of the marine barometer, who was associated with Boyle in the production of the air pump; of John Mayow, who actually made oxygen in 1674, nearly a century before it was supposed to have been discovered by Priestley and Scheele. Professor Bone also discussed Stahl's phlogiston theory—the hypothetical principle of fire or inflammability regarded as a material substance. This theory produced fruitful results and held sway for a century. He then dealt with Priestley's and Scheele's discoveries, the former of whom had given us that great boon to humanity known as "laughing gas" which was greatly used by dentists. In 1754 Priestley obtained what he termed dephlogisticated air, afterwards named oxygen by Lavoisier, the discovery of which formed the germ of the modern science of chemistry. Priestley also showed us how to make soda water, whilst Scheele, the distinguished Swedish chemist, discovered chlorine, prussic acid, tartaric acid and citric acid, and was the first to collect ammonia. The researches of Henry Cavendish, who discovered that water was formed when hydrogen was burnt in air, were also referred to, as well as those of the celebrated French chemist, Lavoisier, on combustion.

The lecture was fully illustrated by a most interesting series of experiments, including the working of a Geryk air pump; Mayow's candle experiments; the heating of phosphorus *in vacuo* and its burning in a bell jar; the burning of a piece of magnesium ribbon to show that the residual ashes weighed more than the original piece of ribbon; explosive soap bubbles composed of oxygen and hydrogen; and the lecture concluded by a demonstration of the burning of barium and strontium chlorates in an atmosphere of hydrogen or coal gas, and of coal gas being burnt in air and of air being burnt in coal gas.

PROCEEDINGS OF THE SOCIETY.

SIXTH ORDINARY MEETING.

WEDNESDAY, DECEMBER 12TH, 1923.

SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., a Vice-President of the Society, in the Chair.

The paper read was:—

PRESERVATION OF ANCIENT MONUMENTS AND HISTORIC BUILDINGS.

By SIR FRANK BAINES, C.V.O., C.B.E.,
Director of Works, H.M. Office of Works.

I do not think it is necessary before this audience to attempt to state a case illustrating the value of preserving our Ancient Monuments and Historic Buildings. They are a part of the culture and history of the British people and I propose to take it for granted that we are in agreement as to the essential need of their retention and preservation. These buildings are a signal record of a previous social tradition which brings down to our mechanical and competitive age a suggestion of a saner spirit and finer method of life. It has been well said that "the present is charged with the past and is big with the future:" and that the more perfect and ordered the record of tradition is, the more the race of man becomes as one; living, learning and advancing. It is, therefore, the more interesting to be able to record that the value given to buildings and historic monuments at the present time would appear to be increasing year by year. This interest and sense of value is not spent upon works involving a soulless repetition of ancient detail and models, an archaistic idolatry of restoration, but is a due and effective renewal of the material and spirit of a past time and its usages, which attempts to give a clear historical synthesis involving a re-orientation of the study of tradition.

Before discussing the question in detail, I should like to suggest to you first of all what we mean when we use the word "preservation." Clearly we do not mean restoration, or replacement of what is gone; we do not mean renovation or renewal. These latter phrases are dangerous phrases; they are sometimes used by people—entirely conservative in their sympathies—as though they were interchangeable with the term "preservation." Of course, they are not interchangeable; and it is necessary to define the word "preservation" as meaning a method involving the retention of the building or monument in a sound static condition, without any material addition thereto or subtraction therefrom, so that it can be handed down to futurity with all the evidences of its character and age unimpaired. Restoration may be a word justifiably describing *a* method of preservation, but I wish to make it clear that that method is not the method advocated here.

There are two main advantages in rigidly adhering to some general interpretation of the term "preservation" such as I have suggested. One is that it is incumbent upon the technician dealing with the work of preservation to sink his individuality to the uttermost and merely to throw up the distinctive character and individuality of the work of the mediæval constructor. You will, doubtless, agree that it is of primary importance that the work of the mediæval constructor should be preserved without any alteration whatsoever, if that is statically possible; and that in no instance should repetition work involving the construction of even technically accurate and perfect replicas of a feature of old work, however beautiful, be permitted.

The second main advantage I have in mind is that the methods of preservation advocated here involve vastly less expense than the methods of restoration, renovation or replacement. Many instances could be given of this, and in these difficult times of financial stringency the virtue is twofold—one, in the limitation of Government expenditure; and two, that the limitation directly preserves unimpaired and in its original form and character, the monument or building being dealt with. Indeed, it should be an invariable rule to spend as little as possible upon the work of preservation of a building or monument. There is, however, need for further definition. The work of preservation should aim at some finality so that repeated returns to the structure need not be made; restless, continual and piece-meal patching of a monument is rightly provocative of criticism. Indeed, with many great structures such a policy would be extravagant in the extreme as the question of scaffolding alone is a prohibitive item of cost.

As to the terms "Ancient Monument" and "Historic Building." The first has been defined as a structure under or above ground which possesses value as a historic or artistic monument. It may be a movable or immovable object handed down from a previous age, which as a structure or erection has specific public interest by reason of its historic, architectural, traditional, archæological or artistic interest.

The term "Historic Building" could clearly be comprehended as coming within the definition of "Ancient Monument," but the expression generally is used to denote a building which still partly retains its character as a building for use, although it may or may not be in use as originally designed. Historic buildings in use must be subject to some elasticity of treatment, more so than the buildings which are not in use as structures to afford cover, or which are not functioning for any purpose as occupied buildings.

The treatment of ancient monuments in the past may be referred to under three headings—the first, regrettably represented by the word demolition; the second, by the word restoration; and the third, by the word preservation.

The first phase clearly can be said to date from the dawn of history and to have been arrested in part only so late as the early years of the 19th century.

The restoration phase approximates roughly with the 19th century, but the effects of this phase are, of course, in evidence to-day.

The true conception of preservation is quite a modern conception, and its early and tentative proposals as a consistent scheme of treatment hardly go further back than the period within the memory of living man.

Demolition applied to buildings which at the time would surely be called historic buildings, and which to-day we should look upon with the utmost reverence and respect, was universal amongst Greek, Roman and mediæval builders.

The expression of national greatness and the rivalry between local communities in the erection of monuments more magnificent than those erected by their predecessors, was always in the past considered a sufficient excuse for the total destruction of earlier work, nor would it appear that any sense of guilt existed when this destruction was undertaken.

Even the great Masters of the Renaissance in Italy, who founded much of their work upon the work of the ancient builders of the past, appeared to be quite content to destroy and to utilize the material with which these older monuments were built, for their own erections. Although there is a record that as far back as the 14th century the City Statutes of Rome banned under heavy penalty the defacing of the vestiges of the ancient city, these Statutes would appear to have been largely disregarded.

The growth of archæological research in Italy in the 15th and 16th centuries may well be said to mark the starting point of a more intelligent appreciation of the works of the past. Practical results did not follow as yet, and when they did follow, the practical work was rather in the nature of restoration than preservation as previously defined.

Even when archæology was studied scientifically, Lord Elgin would seem to have had no compunction in removing the treasures of Greece to this country, while as late as 1877 Cleopatra's Needle was brought to this country and set up by the Thames to decay under the acid-laden atmosphere of modern London.

Without any apparent discrimination the Gothic architecture of France was robbed of its ancient fittings; and similar destruction was being wrought in this country at Salisbury and elsewhere. Attempts were made to classicise the Choir of Chartres Cathedral and St. Méry in Paris, and although the drawings of ancient work published by antiquaries were painstaking to a degree, many of them were found to be comparatively valueless as historical records.

Towards the close of the 18th century and in the beginning of the 19th century, the writings of Sir Walter Scott and the drawings of Samuel Prout assisted in spreading interest in the mediæval architecture in this country—assisted, of course, by the Oxford movement—with the unfortunate result that in many cases the work of a later period, even then of some historic value, was ruthlessly swept away to give place to lifeless replicas of mediæval work and handicraft.

On the Continent there was an awakening of interest in ancient buildings, as is indicated by Government action which took place in several countries from the 17th century onward; and the Papal States and the Provinces of Tuscany, Lucca, etc., now comprising the Kingdom of Italy, issued edicts, aiming at the preservation of historic work. These edicts were consolidated in 1902 and further legislation has taken effect as recently as 1920, while it is interesting to record that the Greeks took immediate advantage of their independence to stop the spoliation of the incomparable monuments for which their country is famous, by the passing of an Act in 1834.

In Belgium, church property was safeguarded by a royal decree in 1824, supplemented in 1835.

In Germany, regulations for the preservation of its ancient monuments have been framed since 1815, and although they would not appear to have statutory sanction, much respect was shown for their monuments. Indeed, Germany is richer at the present time in mediæval church furniture than any other country of Europe.

Scandinavian countries were in the field as early as the 17th century, aiming at the preservation of their antiquities, while in France the appointment of a General Inspector of Historic Monuments in 1834 was followed by numerous enactments aiming at preservation, although the understanding of that term in France, unfortunately, would appear to be vastly different from the understanding in England.

In Austria, a Royal Central Commission was established about 1864, and in Hungary ancient monuments were placed under protection of the State in 1881.

England, in accordance with her democratic social organisation, appeared to await the expression of public opinion before committing herlf to statutory enactments, and it was not until 1822 that the first Bill dealing with the subject became law. Generally, privately owned monuments and historic buildings in Europe are not under Government control, with exceptions in Italy, Hungary and France. In France, such monuments are not usually scheduled, but compulsory purchase is possible, as is also the case in Denmark and Greece. In Spain and Saxony official pressure is exercised. Switzerland even aids private individuals financially in the upkeep of historic monuments. Sweden and Norway have got so far as to lay down the principle that a monument may be of such an age that it may no longer be held to be private property, while Greece forbids the erection of lime kilns within two miles of classic ruins—for very obvious reasons. This, however, did not prevent the demolition of the old Venetian Tower on the Acropolis at Athens about 1880. In India, ancient monuments were protected by legislation in 1904, and certain of the States of America have laid down provisions in their laws, for conservation.

Unfortunately, this general awakening of a regard for National Monuments caused an outpuring of money raised voluntarily or by compulsion, which went into the coffers of the would-be conservers; and, as a result, great works were undertaken which aimed not at preservation, but at restoration and renovation and even at the removal of such work existing which did not approximate to pre-existing remains.

Ruskin did, indeed, preach conservation consistently, but even those who agreed in principle with preservation of ancient monuments, appeared to apply in practice the principles of restoration. I could detail at considerable length, if the time at my disposal would allow, a sad list of examples of this practice in France involving a vast expenditure upon work of repetitive rebuilding. Such instances would extend into pages of matter, illustrating the grievous and heavy losses which have been incurred; partly perhaps as a consequence and a result of the scholarship and knowledge of M. Violett-le-Duc.

In England, as in France, the damage done owing to over-prodigality of expenditure has been serious and irreparable. For example, to give one instance alone, the restoration of Worcester Cathedral between 1857 and 1874, which involved an expenditure of considerably over £100,000, resulted in handing down to us a building that is externally to all intents and purposes a modern structure. There is no record that major structural problems were involved here, but a great deal of money was spent on refacing owing to the character of the red sandstone of which the Cathedral was built. During the first 50 years of Queen Victoria's reign, well over £1,000,000 was spent on 20 of our cathedrals, with results that the judicious can only deplore; many of these buildings are now largely modern, particularly is this so in the cases of Worcester, Chester and Lichfield. The east window of Carlisle and the west window of York Minster, probably the finest examples of flowing tracery in this country, and perhaps in the world, were lost to us; the whole having been renewed in both cases. Need I say again that replicas of ancient work, however perfectly and accurately executed, can have no real historic or archæological value whatever?

Again, long lists of instances could be given of what we have lost in England during the restoration period; the records exist and afford the most painful reading to-day, in the annual reports issued by the Society for the Protection of Ancient Buildings, founded in 1877, to educate the public on the lines of conservation and preservation as opposed to restoration and renovation.

A word of sincere appreciation of the great work carried out by this Society is, I think, called for here. Their aim has been consistent throughout: namely, to enlist the sympathies of the British public in the conservation of every fragment of old work as opposed to repetitive restoration; and if such views are slowly percolating downward to that hypothetical person "the Man in the Street," it is largely due to the fine propaganda work done by this Society.

Now that legislation is taking its hand in dealing with the problem, certain results accrue which, it is claimed, should instruct the public still further in the importance of the principles laid down. Certain classes of ancient monuments, etc., have been protected by Parliament by Acts passed in 1882, 1900 and 1910. These Acts were repealed in part by the Ancient Monuments Consolidation and Amendment Act of 1913, and this Act, though of considerable importance, is strictly limited in scope, providing, as it does, a saving clause for buildings used as dwelling houses, otherwise than by persons employed as caretakers, etc., and excluding also from the definition of the expression "Monument" any ecclesiastical building used for the time being for ecclesiastical purposes. This exclusion in principle rules out all the great English cathedrals, many of the great castles and monastic buildings and nearly every church in this country; which should make it clear that the importance of obtaining agreement to the principles of preservation versus restoration is greater now than ever.

It is desirable to attempt to lay down in some detail how the principles which I have briefly suggested here are interpreted with regard to ancient monuments and historic buildings under the charge of the Crown, and I propose to do so by throwing on the screen certain of the buildings in process of preservation, illustrating the character of the work executed and the way the principles are interpreted in specific work.

Before doing so, I should like to make it clear that the Departmental organisation under which this work is carried out utilises the Ancient Monuments Advisory Boards appointed for England, Wales and Scotland, and it should be mentioned that our Chairman this evening is a most distinguished member of the English Advisory Board. The archæological and historic aspects of the buildings are further safeguarded by the appointment of a Chief Inspector and Inspectors of Ancient Monuments, who advise the Department on all matters of archæological and historical moment, which arise in connection with the proposed methods of preservation of the buildings. It has often been said that the Ancient Monuments Consolidation Act of 1913 imposes certain restrictions upon the freedom of the private citizen; this is unquestionably true and as a result of such restrictions the practice of the Government in regard to the National Monuments in the charge and ownership of the Crown has been consideraly affected and modified. This point is of material importance, as it is clear that in imposing restrictions upon the private citizen the Government must assume an obligation to set its own house in order and to see that the national monuments under its control are properly administered and preserved.

There are, therefore, two classes of monuments in the charge of the Crown—

(1) Crown monuments and historic buildings often part of the hereditary possesson of the Crown; and

(2) Buildings and monuments transferred to the charge of the Government under the provisions of the 1913 Act.

The first point I wish to bring out is that with regard to the latter class of buildings, they are generally transferred to the Crown suffering from the most distressing neglect and even ill-treatment; all are in a state of general instability and active decay. I propose to give instances of this upon the screen.

The points I wish to bring forward are:—

(1) The tremendous destruction of the buildings due to neglect and decay; and

(2) The enormous growth of ivy, shrubs and trees even, upon the wall heads, which in many cases have rent the masonry asunder for lengths up to 30 feet and for widths up to a maximum of 1ft. 3in. to 1ft. 9in.

This problem of preservation, therefore, in these circumstances is quite a new one, a problem which did not face the mediæval constructor.

The problem may be briefly described as follows:—

To attempt to retain in its existing form a partial structure, when all its original equipoise of thrust and counter thrust has been destroyed by the failure of portions of the building. For example, you may get an arcade standing as detached overloaded columns without any support from the thrust of the original vault and the counter-thrust of the original aisle roof, buttresses, etc. If this arcade stands at such an angle of inclination from the vertical that it is at the moment unstable, the problem is a serious one. Such a problem could be dealt with reasonably simply if it was possible or justifiable to restore the original static condition of the structure. This, however, would involve so much reconstruction and restoration that it must be ruled out of consideration. The problem, therefore, is clearly entirely different from that of the mediæval constructor and also from that which faces the architect and civil engineer of to-day in designing a new structure; and such a problem has to be dealt with entirely on its merits.

Generally, the problems must be faced without any formal or set ideas as to their solution. The first principle laid down is the need to ascertain as clearly as possible the static condition of the structure under all its conditions of decay, incipient and partial failure, actual collapse, etc., and I propose to show upon the screen a plan made of Tintern Abbey which I would describe as a statical or technical survey of the building, showing clearly before any work is done the condition of the structure and the problems which have to be faced.

Tintern Abbey is one of our most interesting and romantic Cistercian Abbeys. The date of the existing work is generally that of the end of the 13th century, when the present church was built to the south and east of the older church. You will see that the north arcade of the nave has fallen, carrying with it the whole of the vault of the nave, leaving the great south arcade standing to a height of 68 feet, existing merely as a series of overstressed, distorted piers, eccentrically loaded and unsupported by any thrust of vault or counter-thrust of aisle roof, etc. The thickness of this arcade at the top is 5ft. 6in., and the weight carried by each pier is roughly 210 tons. The wall is seriously overhung to the north to the extent of 18in., inducing excessive compressive stress on the north side of the piers and a tensional stress on the south side of the piers. As a result the piers are found to be actually failing under crushing. Many of the stones both of the piers and the caps have been fractured completely through, some of them being in a thoroughly shattered condition.

The original proposal, before the Department undertook the charge of the building, was to take down and rebuild plumb, a great proportion of the arcade above the arches. The Department, however, decided that such a course of action would ruin the amenities of the building and generally the scheme which was undertaken was to relieve the eccentric stress on the north side of the piers, and also to relieve them entirely of stress due to wind pressure. This was done by the institution of a great lattice girder of the N. type anchored into the wall of the south transept and to the wall of the west gable, designed to move under temperature stresses and under slight oscillation of the arcade. It would take more than the time at my disposal to detail the theory underlying the design and erection of this girder, but I wish to make it clear that the scheme was devised to preserve the amenities of the arcade as seen from the nave, which otherwise would have had to be heavily buttressed. To use modern knowledge and experience in obtaining that result would seem to be fully justifiable. It has been sometimes contended that in the preservation of historic buildings only the materials and methods of the mediæval constructor should be used. Such methods could indeed be used, if restoration could be considered and the principle of preservation only, departed from. Then a lime-built masonry structure could be devised which would reinstitute the thrust and counter-thrust of the original building, and perhaps reach a state of statical stability without utilising modern knowledge and the methods of our day.

The loss, however, by following this practice would be enormous. At Tintern it would involve the rebuilding of the whole of the north arcade, the whole of the stone vaults of the nave and aisles, and a practical reconstruction of the Abbey Church. Such a course could only make the judicious grieve; and, indeed, in these days when the complete preservation, without addition, of our historical monuments is the principle which guides us, such a course of action could not be contemplated. Further, the expenditure involved by such a scheme would be vastly greater than could be considered by the Government to-day, and it is clear that when Tintern Abbey is completed, within a very short time, the works of preservation will not be apparent, and in a few years the hand of time will place its softening and enriching imprint upon the building once more, when the instructed public can view this wonderful monument in a form showing its original features without any unwarrantable disturbances or additions thereto.

There were other problems at Tintern which I will briefly glance at. One was to retain the great overhanging fragments of the fallen North Arcade hanging to the north west pier of the crossing and to the west gable. This was a difficult problem, and was overcome without disturbing in any way the original face stones which were left in position, although the eccentric loading transferred to both north west pier and west gable was as much as 90 tons.

The next building I want to show you on the screen is Rievaulx Abbey. This is the earliest Cistercian House in the country, founded in 1131. Its situation is beautiful, at the head of a rich deep valley formed by a bend of the River Rye below Old Byland. The Abbey stands immediately beneath a ridge of hills, and is built on a series of terraces cut out of the foothills of the range, the church being founded on the solid ground and the monastic buildings in certain instances on made ground, while the Frater, owing to the steep fall of the ground is carried upon sub-vaults. Owing to the importance of founding the church on solid ground, it is built parallel to the range of hills upon the first cut made in the slope, and it stands, as a result, roughly north and south instead of east and west. Indeed, had the mediæval builders been so rash as to throw the church due east and west a portion would have had to be built upon filled ground or upon subvaults, which would have enormously complicated the problem.

Of the church, only the presbytery and the choir with the transepts and the east arch of the crossing remain; and the nave, when it was taken over by the Crown, presented a dimpled mound of ruins where fallen masonry and soil was heaped up to a height of 16ft., as shown upon the screen.

The next view shows the church with the nave excavated, and the bases of the Norman piers displayed to view exactly as they were found. I shall not have time to deal with the history and character of the building, as my aim to-night is to give briefly particulars of the works undertaken to preserve the structure.

These ruins had been used as a quarry by the neighbourhood for many years, and certain difficult structural problems were involved in their preservation. As an example I show upon the screen the crushing and failure which was in evidence in the spandrel above the south west pier of the chancel. The condition of this spandrel was dangerous in the extreme, and the method adopted to preserve the stability of this arcade and the chancel was to remove the fractured stones one by one and to recore the whole of the spandrel and pier above, with strong reinforced concrete, afterwards replacing in their exact positions the stones removed for the purpose of executing the work. No single new facing stone has been used, and even in the 12 months which has transpired since the completion of the work no trace of what has been undertaken is observable.

This is only one of the problems involved in this great building, and it is hardly realised how serious the difficulties are in cutting out crushed and failing masonry under a load of over 200 tons, when the slightest error in executing the work might cause a slip involving the downfall of certainly a large portion of this great arcade.

I now propose to show you on the screen Jedburgh Abbey; one of the finest of the Border Abbeys, founded by David I. in 1118.

It is remarkable that so much remains of this Abbey, bearing in mind that it was twice burnt and three times pillaged. The earliest work is in the transepts, the lower part of the tower and the west end of the chancel. The nave is a very fine example of transitional work and you will see from the screen that the previous methods used to retain the nave in position postulate—

(1) That it was falling inward: and

(2) That it was falling outwards;

and in order to obtain the maximum advantage from both theories, great timber struts were erected between the arcades in the nave and also strong steel tension rods to resist the postulated outward movement of the arcades. As a matter of exact appraisement, however, the arcades required neither of these methods of strengthening and as if to show scorn for the methods adopted, the struts were found to be rotten at their bearing upon the walls, and the birds were nesting behind them. You will see what a vast improvement is made by removing these unessential means of preserving and strengthening the nave.

The problem of Jedburgh was one of the greatest with which the Department has had to deal. The tower was definitely failing and was in a bad state in the 15th century, as at that time the south-east and south-west piers of the tower were rebuilt by Bishop Cranston. The Norman north-east and north-west piers were left, however, and although their condition must have been serious in the 15th century, they were still further over-stressed by an addition to the upper stages of the tower in the 16th century. In the past, apprehension of the total collapse of the tower clearly existed; and the two Norman piers were encased in stone walling as shown upon the screen, while the north arch of the tower was solidly built up. Even this was not sufficient, and within quite recent times heavy modern brick buttresses and raking shores were added to the piers. Norman work gives the appearance of great solidarity and strength, but unhappily this appearance is often deceptive. This was the case at Jedburgh, where the piers were faced with rough ill-wrought ashlar only, reasonably well worked on the face, but with unsatisfactory beds joints inducing point loads on the stones. The core of these piers was made with rough rubble and weak mortar, which had no tensional strength wha soever, and which was found to be a dry and non-cohering mass, such as would have shot out from the piers had they been opened at the base without full precautions.

It is believed that before the building was handed over to the control of the Government, a suggestion had been made to take down the tower and rebuild it, at a very heavy cost. The methods followed by the Department, however, could not contemplate this: and, first of all, an attempt was made to grout up the piers with cement. This proved a failure as an examination showed that the fine dense cement grout merely lay inert within the piers in the dusty core somewhat similarly to the action, say, of molten lead after being poured into dry sand. When this was found, the proposal to grout was at once discarded, and a dangerous and difficult scheme was devised for the recoring of the two Norman piers. This was a very risky and precarious work as the load on each of the piers was over 600 tons and the tower had sunk 4in. with a resultant out-throw to the north of nearly 24 inches. The really terrible condition of the piers was not fully ascertained owing to their being so closely encased with modern masonry, etc., but it would be impossible to exaggerate their condition as can be shown by the following views thrown upon the screen. The scheme of srengthening proposed when the state of the tower was ascertained in 1913 was first to consolidate the upper portion very thoroughly by cement tamping and grouting, finishing with lime pointing. The great arches were centred and heavy steel needles were carried through the tower supported on clusters of four 14in. x 14in. deadshores. The process of recoring was then slowly undertaken, certain of the face stones being removed, strong jacks being inserted to support the face above, and heavy steel bars driven into the pier to prevent any fall of the core on the masons working within the piers. The process was slowly extended right up the piers and carried over the arches, and while the work was being done an accurate measuring apparatus was devised to show any movement of the tower of the minutest kind, either as to sinkage or out-throw, and after the re-coring was complete the two tower piers were carefully underpinned, and the infilling walls and buttresses removed, so that the great Norman drums are displayed with all their fractures disclosed and the great bulges remaining to view.

The actual cost of the work undertaken at Jedburgh by these methods which were slow but inexpensive, was probably one-tenth (for the whole church) of what it would have cost to take down and rebuild the tower alone. To-day the tower stands absolutely as it was with no additions thereto beyond the internal reinforced core, which is now carrying the load, with all the modern additions removed, and the amenities of this fine building are entirely preserved.

I cannot resist showing you one photograph of Carnarvon Castle, but time will not allow me to detail the works undertaken here. It is probably the finest defensive castle in this country, and, indeed, in Europe—one of the great Edwardian defensive castles dating from 1285-1322. On this building alone we could usefully spend an entire evening; but as the works of preservation here were mainly of normal character, I do not propose to describe them in detail.

I now proceed to show you on the screen examples of the method of preserving Whitby Abbey. The difference made in this building since it was taken over by the Government is very great, as it was suffering from destruction as a result of bombardment during the war, while the nave and the crossing were littered with fragments of the fallen church.

The history of the Abbey is of extraordinary interest as it was first founded upon the present site in A.D. 657, but the portion which remains is the 13th century church, consisting of nave and choir, with aisles, transepts and originally a lofty tower at the intersection, all of which were encumbered with great masses of fallen masonry from the vaulting and superstructure which fell in the nave in 1762 and the great central tower which fell in 1830.

Our recent excavations have revealed a large section of the plan of the Norman church, which will be shown in outline on the floor of the present church.

The excavations to the north of the church are now disclosing some very early buildings, which appear to have been constructed in part of "Wattle and Daub." The excavations are far from complete at the moment, but it would appear that eventually a large portion of the pre-Norman and 12th century buildings can be disclosed, the two former at least in plan.

I now show upon the screen the west front of the church, giving its condition before the bombardment by the enemy, after the bombardment and after treatment. The problem in dealing with this front was very difficult as many of the stones were shattered into fragments and the greatest difficulty was found in identifying them and replacing them in their true position. No moulded and wrought stones were put back unless they were original, and the whole of the work shown on the last slides after the works of preservation had been completed, is such that no intelligent observer could do other than perceive accurately what is original work and what is the later work of strengthening and repair.

In Kirby Muxloe we see an example of a fortified Manor house of Tudor times, which was commenced in 1480, apparently upon the site of an earlier moated house. It is of brick construction throughout, even to the turret staircases with their complicated and enriched winding vaults and is a remarkably fine example of first-rate brickwork of the period.

Again the building was handed over in a state of utter neglect, as you will see from the screen.

The next view illustrates its character and appearance after its preservation has been accomplished by the methods which I have sought to detail to you here.

The problem of preserving a brick building is entirely different from that of a stone building, particularly where the bricks are scaling and flaking through weather and age, and through the action of growth of all kinds.

No attempt has been made, however, to re-face the scarred brickwork, but the flaking and decaying brickwork has been seized by a mastic cement and the original faces retained without any addition.

Byland Abbey, a view of which I have previously shown on the screen, was in a serious state of neglect when it was handed over to the control of the Government. It is situated on the rich fertile plain at the foot of Combe Hill, in the North Riding of Yorkshire, and there was little remaining above the ground level beyond stumps of walls heavily covered with ivy, all of which were in a state of complete disintegration and decay. There, again, the building appears to have been used as a quarry for those requiring materials for building in the district. Buttresses were robbed and the ashlar masonry removed in many instances as far as could be reached without scaffolding. It is difficult to exaggerate the appalling condition in which this building was found, and the regret we must feel over this is emphasised by the wonderful finds of enriched and carved work which we have made in excavating the church.

The magnificent detail of much of the work of this building could hardly have been apprehended before its preservation was undertaken. Moulded caps and bases, corbels and carved springers, etc., have been found which, for their simplicity and beauty of design and astonishing assurance of execution, are difficult to rival. Quite a large area of fine vitrified tile paving has been exposed in the chancel which, although somewhat rough in manufacture, has special merit for its design and planning of colour scheme.

The next building which illustrates the methods followed by the Government is Goodrich Castle, the earlier history of which is not known. It is mentioned in 1204, while the small and very perfect Keep clearly suggests that the work is among the earliest of its class in the country. The present remains, apart from the Keep, would appear to date from Norman times until the reigns of Henry V. and Henry VI.

The problem here was again grave, because of the consistent neglect of the building for well over 200 years. The stone used in the castle is a soft red sandstone, without any great strength, and this has weathered very badly and the greatest care had to be exercised in dealing with the stonework, which was fractured and split apart in many cases by the roots of ivy and young trees growing upon the wall heads.

To illustrate this highly dangerous condition, only a few weeks before the building was transferred under the Ancient Monuments Act a length of the north-west curtain wall, totalling a weight of 200 to 300 tons, fell into the moat, leaving little or no evidence of the main cause of failure, but illustrating very definitely that the masonry had little strength in resistance to shear.

We find this castle was "slighted" by an order made by Parliament in 1647, and it is probably due to this order that the castle was in such an appallingly defective condition, although it is surprising that so much remains standing, nearly 300 years after the order was made.

I propose to show on the screen, slides illustrating the character of the building before treatment and after, although the time at my disposal will not allow me to detail very particularly the works undertaken.

[Sir Frank Baines also showed upon the screen views of the following buildings and structures:—

Netley Abbey.
Hampton Court Palace.
Westminster Hall.
Richmond Castle.
Huntingtower.
Stonehenge.
Maes Howe.

Mousa Broch.

Maiden Castle, Dorchester,

explaining briefly the character of the works of preservation undertaken in each instance and illustrating how the scheme of preservation was strictly relative in every instance to the peculiar character of the work which remained.

Particularly illuminating was his description of the repair work undertaken to the great earth work of Maiden Castle, which consisted largely in repairing the huge scars of eroded chalk from the sides of the slopes and finally involved the retention of a man on this great monument of 115 acres in extent, to keep down rabbits and prevent their commencing again the destruction of the great slopes of the valla, etc.]

DISCUSSION.

Mr. Ernest Law, C.B., said that he was delighted with Sir Frank Baines's paper, the more so because he followed the line which the speaker had always advocated with regard to restoration. He had come to the meeting feeling that possibly he might find some weak point in the armour, or that he might be able to answer some criticism, but the paper had left nothing to wish for in those directions. Those who valued our old historic buildings, and who had the sentiment—not the sentimentality of ivy, against which he had inveighed for the last twenty years—of old associations, were now told, if they might believe the latest science, that these buildings had stamped upon them in their molecular formation everything that had happened within and underneath their walls. He agreed that it was impossible to fix any definite rules to be followed in restoration. Each building must be treated on its own basis, and it should always be borne in mind that buildings which were not uninhabitable ruins —buildings, that is to say, which still served some existing purpose—must be dealt with in a different way, perhaps with greater latitude in restoration, than most of the buildings which the lecturer had shown the Society that evening. If in these cases new work was put in it was better that it should harmonise with the old rather than it should flagrantly dissociate itself from the old. The questions involved here were difficult, but they deserved threshing out. In the paper the principles enunciated were those which most people who valued ancient buildings would support, and a great debt of gratitude was due to Sir Frank Baines and Mr. Peers for the wonderful work they were doing and the enthusiasm and high spirit in which that work was carried through.

Mr. Edward P. Warren, F.S.A., F.R.I.B.A., expressed his admiration for the work done by Sir Frank Baines. It was a great relief, after things had gone on so long without any Government recognition of the claims of ancient monuments, that they should now be in secure hands. He wished strongly to support all that the lecturer had said against ivy. He himself had been responsible for removing tons of it. On one Oxford College with which he had had to do, it acted in the most insidious manner by destroying the mortar. The secretions of acid by the ivy led to the steady disintegration of the wall, and then, by working its roots and filaments into the crevices, it shattered and destroyed the beautiful stonework. Some of the old stonework at Oxford was particularly liable to decay, and was very unsatisfactory. The task of those who had the custody of old buildings was not an enviable one. They laboured under constant anxiety lest they should destroy in attempting to preserve. In the case of buildings still in use the problem presented was different from that of buildings the use of which had passed away. His own particular responsibility had always been in connection with buildings which still had a roof, not those which had been shattered beyond habitation, and here some special consideration applied. He wished to express his personal thanks to the lecturer.

Mr. A. R. Powys (Secretary, Society for the Protection of Ancient Buildings), thanked Sir Frank Baines for his excellent paper. The country should be congratulated on having an Office of Works that put so much energy and thought into the repair of our buildings. It was only necessary to travel abroad to discover how far otherwise it might be. He noticed, from Sir Frank Baines's selections that evening, that the Office of Works up to now seemed only to have dealt with the more extensive and larger buildings. He would like to see His Majesty's Office of Works take over some examples of smaller buildings—cottages, for example, of various periods, and built in the different traditions obtaining in the different parts of the country. When buildings of this kind were kept in the same careful way as the castles and large buildings, a very great thing would have been done for the country.

Mr. T. Raffles Davison feared that in spite of Sir Frank Baines's warning, a very large number of people in this country would prefer to keep the ivy, notwithstanding the ruin that it wrought. He remembered sketching many years ago one of the buildings which had been illustrated that evening, and he noticed that one of the arches had been completely spoiled in outline by the ivy. To that extent he was with Sir Frank Baines, though he must confess to some sneaking love both for the ivy and the ruin. If Sir Frank Baines could show them a way of keeping both he would be conferring a great benefit.

Mr. W. A. Forsyth said that he had greatly appreciated Sir Frank Baines's paper. Sir Frank was a master exponent of his subject, and a master craftsman in his superintendence of the work.

The country was to be congratulated on having what he considered to be an ideal Government department in the one which was concerned in the care of our old buildings. It was a department unrivalled by any similar department in other countries in the care and thoroughness with which the buildings were repaired. Sir Frank Baines had said that he did not go to the building and say to it, "This is what you want"; he waited for the building to declare what it wanted itself. That seemed to the speaker absolutely sound. The fundamental point which never varied was that no two buildings were alike, and the treatment they required was different on every occasion. The paper had been most fascinating, and if he ventured to make a criticism it was not that he was unappreciative. He admired Sir Frank Baines's vigour immensely. He had laid down the axiom that each building was to be treated as it required, but he had also told them that restoration was not to be attempted on any account whatever. Personally the speaker thought this rather a dangerous principle. There were little bits of buildings which did require some sort of restoration in order that there might be a record in stone of the original design. He thought it was risky to lay down that law. He instanced the cloisters of Westminster Abbey. The entrance to the Chapter House there was one of the most beautiful pieces of thirteenth century work ever wrought. He remembered it thirty years ago, when it was in beautiful order and full of definition, and one could see what was intended in the original carving. That had disappeared, however, in the atmosphere of London; the carving was subsequently limewashed, and now the outline was lost. That was an example which should make one hesitate before laying down the law about excluding restoration. On one point he would like a little more information. He would like to know why the grout failed at Jedburgh. Sir Frank had said that on cutting out the wall, owing to the dust in the crevice the grout had merely mingled with the dust and had not adhered to the structure. But the first operation in grouting was to remove the dust. The dust must be removed before the insertion of the grout. It should be removed either by sucking or forcing it out. He had never himself sucked it out, but he had blown it out through air holes. It was most necessary to get the dust out. Then he must comment upon Sir Frank Baines's use of ferro-concrete in these buildings. Sir Frank had said that it was almost an impossibility to resort to mediæval methods of building in the repairs. But there were many examples of mediæval repairs; they declared themselves for all time. It was not only a matter of style and design, but of material and workmanship. One could always see a repair in mediæval work as between one period and another. At Tintern Sir Frank had used ferro-concrete to a large extent. Ferro-concrete was a modern combination of cement, concrete, and, as a rule, mild steel. The speaker understood that Sir Frank had used the mild steel persistently. Mild steel was one of the most ready forms of ferrous metal for rusting. Sir Frank had put into these buildings great masses of ferro-concrete. Ferro-concrete had only been in general use for about thirty years, and Sir Frank had experimented by putting this ferro-concrete into these mediæval lime-built flexible walls. It was largely theory as to the behaviour of ferro-concrete under these circumstances and it did not do to rely on laboratory tests for the behaviour of ferro-concrete in old walls. The tops of the walls at Tintern had been stiffened with very large ferro-concrete beams. The speaker could not imagine from his experience that these ferro-concrete beams were going to lie quiescent for centuries in that wall without doing any damage. Moreover, when the time came, as it must do, to repair these ferro-concrete beams, how were they going to be reached without dismantling the walls? It was almost impossible to repair a ferro-concrete beam once it had been put into its place. Sir Frank would say that it would last five hundred years at least, but the speaker's answer would be that that was only theory. From his own experience of reinforcement generally, he thought that this method would produce failures in course of time, and much more quickly than some of them thought. It seemed to him that at Tintern Sir Frank might have developed a part of the preservation upon an ordinary stone corbel basis and let the stone corbels show. He had been rather zealous to hide his own handiwork. The speaker wished that he would show it, and not bury it in the walls.

MR. WARREN remarked on the question of reinforced concrete that some concrete reinforced with iron was in perfectly good order.

MR. FORSYTH said that, unfortunately, Mr. Warren's experience did not coincide with his own.

SIR FRANK BAINES, in reply, said that he quite appreciated Mr. Warren's problem—that of stone decay. That problem alone might occupy many meetings, and therefore he had left that aspect entirely alone on that occasion. He wanted, in the few moments left to him for reply, to try to convince the last speaker. One of his points concerned restoration. In the speaker's view they were not justified in restoring or adding anything to the structure that was there. He agreed that it might be desirable to have some record of beautiful decorative thirteenth century work which was fading away, but what he maintained was that such record should be produced elsewhere. The monument itself should be left as it was. Any replicas should be careful and accurate records of work constructed apart from the building which was to be preserved. With regard to Mr. Forsyth's point about grouting, he ought to have made it clear in his lecture that he was in entire agreement with the view that the essential of grouting was to exhaust the dust before starting the actual work.

But when the proportion of the dust to the whole of the internal content of the core was so high as to amount to 50 or 60 per cent. one dared not exhaust the dust. The matter then became one of trial and error. He and those who worked with him at Jedburgh did not really think it would be successful, but they exhausted a certain proportion of the dust and then started the work and put in the grout. They found that the core was so hungry and thirsty that the dust was partly absorbed and the grout lay inert like a mass of molten lead poured into dry sand. He next went on to deal with the question of reinforced concrete. He admitted all that Mr. Forsyth had to say on that subject. He honestly did not know what reinforced concrete would do in the next five hundred years. But his aim was to introduce a material which had tensional value where tensional value was required. It was, frankly, for its tensional strength that this modern material was applied in an ancient structure. He had not mentioned five hundred years in his paper, but he did believe that ferro-concrete would last for five hundred years, though, of course, he could not give any proof of this; it was simply a matter of opinion. He was not a reinforced concrete crank, but he thought there was justification for using it because they could not reproduce the statical scheme of the original structure. With regard to taking out the beams, they could, if necessary, be taken out in the same way that they were put in, although he would tremble at the job, because the taking out of really good reinforced concrete was a very difficult proposition. Mr. Forsyth had spoken as though the modern work should not be hidden. It had been said to him in connection with the roof of Westminster Hall, "You ought to have painted your steel work bright vermilion, and let it be seen by everybody." But his own strong feeling was that the problem of preservation demanded absolutely the sinking of the individuality of the technician dealing with the problem. The reality which dictated to him was the monument itself. His pride in Westminster Hall was not that he had produced a fine statical scheme as such, but because that fine statical scheme was largely, if not entirely, unobserved by a person looking at the wonderful mediæval work. It was not that they were trying to hide their light under a bushel; they were frankly seeing if they could disguise it in order that by so doing the amenities of the old work might be entirely preserved. His treatment of the subject in his paper had probably been far from clear but the subject was so huge that he was learning something fresh every day, and he really felt that now he knew less about the preservation of ancient monuments than when he started.

THE CHAIRMAN (Sir Aston Webb) said that there were three things undoubtedly that did largely affect these ancient buildings—namely, stone, cement, and iron. These were all subjects for discussion, but he would like to say a word about stone. The decay of stone was one of the serious things for the whole country. Quite recently this decay had extended and had become much worse to an extraordinary degree. Sir Frank Baines had brought this matter before the Board of Research and had asked for a Committee to go into it. The speaker was made chairman of that Committee, and the Committee was meeting constantly with scientific men and architects to discover whether something could not be done to preserve the stone which was now decaying in so extraordinary a way day by day. The work was likely to be so protracted that he did not suppose he would live to see the report issued. Many of the experiments put in hand might take years to fructify, but, still, they were doing all they could with the aid of the experts who were giving their priceless knowledge and experience with a view to discovering whether there was any preservative of stone. With regard to cement, he thought it was a very useful hint never to use cement in pointing the stone. Cement seemed to have a most deleterious effect on the edge of the stone. It came out in slight efflorescence, and the edge showed decay all round. Cement certainly ought to be kept entirely away from the surface of walls, it was a most destructive thing, and its action was not yet fully known. With regard to iron, he did not speak as an expert at all, but he had always understood that iron bedded in cement lasted very well, and he had certainly seen iron so bedded which came out as bright as when it was put in. But iron bedded in lime was deleterious. Christopher Wren, who never seemed to make mistakes, did make one mistake when he used iron in the great piers of St. Paul's Cathedral, and the iron in consequence swelled and did great damage. Iron was quite a dangerous thing to use in that manner, quite as dangerous as cement. There was no knowing when it stopped, when it was still, or when it would decay. In the piers the iron rusted and seemed to divide in two parts. There was much more that could be said, but the hour was late, and he would ask them to accord a very hearty vote of thanks to Sir Frank Baines for his paper and his beautiful lantern views. His views of the buildings before they were touched by the hand of the preserver were of very great and in some cases of priceless historical interest.

The vote of thanks was accorded unanimously, and the meeting terminated.

PERSIA.

LACK OF COMMUNICATIONS.

In his recent report on the trade and industry of Persia Mr. R. H. Hadow, the Secretary in Charge of Commercial Affairs in Tehran, states that setting aside administrative and political difficulties, the principal difficulty with which trade has to cope in Persia is the lack of suitable or modern means of transport or of methods of interior communication. Persia, by reason of her geographical position, the difficult nature of her mountainous country and the natural inclinations of the majority of her inhabitants, is in the position of a mediæval merchant trying to do business in a twentieth century world. The numerous parallel mountain ridges divide her trade routes into a series of separate entities; she is not yet equipped with modern roads fit for motor transport; her railways are as yet only projected, and she has no means of river communication. She has, therefore, perforce to rely on the native cart, the camel, the mule, and the donkey, except along the three roads from Duzdap to Meshed, from Tehran to Enzeli and from Kazvin to Khanikin, where roads more or less fit for light motor transport have been made of recent years. Of these routes the first and last connect with a railway at Duzdap and Khanikin respectively and so serve as important links for Persia's foreign trade, while from Enzeli on the Caspian, ships transport merchandise to and from Russia and the Caucasus. Yet even along these routes the burden of tolls for the upkeep and protection of the roads themselves weighs heavily on both mechanical and animal transport.

TRADE ROUTES.

(1). *Bushire-Shiraz-Isafahan-Tehran.*—The road itself is not metalled and except along the portion between Bushire and Shiraz which was partly completed by the South Persia Rifles it is neither laid out nor graded, being in fact a caravan track. During the summer and autumn it is, however, used by country carts as well as pack animals, but the formidable passes between Shiraz and Bushire make it impossible for wheeled transport to use this section for commercial purposes. It has no bridges or culverts and the rivers and marshes make certain sections impassable during winter and spring. Nevertheless a large portion of Persia's foreign trade at present passes along this route. The Ministry of Public Works contemplates building this road shortly if the necessary funds are available.

(2) The *Ahwaz-Isfhhan* road through the Bakhtiari country. A caravan track used largely by pack animals and impassable for wheeled traffic.

(3) The *Duzdap-Kerman-Yezd-Isfahan route.*—A caravan track passable at certain times of the year by light motor cars. Frequented by merchandise using the Duzdap Railway which was extended during the war from Nushki via Dalbandin to connect India with Persia. Exporters of carpets from the Kerman district have during the past year used this route in preference to the mountainous road from Bander Abbas to Kerman, although the latest reports state that owing to raids by tribesmen on the road between Kerman and Duzdap the Bander Abbas route is again coming into use.

Light motor lorries and Ford vans have been employed to some extent in this export trade but, as in the case of almost every other road in Persia, the lack of repair and petrol depots except at long distances and the rough nature of the roads necessitate carrying an undue weight of petrol and spare parts, and consequently make it unprofitable to use motor transport in Persia except for light and valuable merchandise or for transporting passengers. Cars used are mostly Ford touring cars or vans which on account of their simple and cheap construction and high ground clearance are popular in Persia. Should the projected development of proper motor roads be carried out Persia should, in the absence of railways, provide a good market for motor cars, light lorries and motor accessories. Price, rugged construction and simplicity are, however, essentials if makes not not yet known in Persia are to be popularized.

(4) The *Bander Abbas-Kerman* road.—Formerly used for the export of the greater part of the carpets and rugs made in the Kerman district and still a caravan route from the Persian Gulf for this and other merchandise to and from Central Persia. Owing to its mountainous nature it is only passable for pack animals and it is often impassable during the winter on account of snow.

(5) The *Tabriz-Hamadan* trade route, which connects Persia in normal times with the Turkish import and export route via Trebizond. A recent revival in export of piece goods through Tabriz has brought this route into use of late, but trade in North-West Persia has suffered from severe depression owing to the partial closure of the Trebizond route to Persia. The Julfa-Tabriz railway connects Persia with the Caucasan railways but is at present badly in need of repair and only occasional trains can be run when sufficient freight can be secured.

(6) *Tehran-Meshed.*—An unmetalled but carrossable road much frequented by pilgrims on their way to the Holy Shrines of Iraq or of Meshed. Also used by traffic between East Persia and the Caspian Sea ports.

A road to connect Tehran with the Caspian at Bandar-i-Baz is also at present under construction.

CESSATION OF TRADE WITH RUSSIA.

Next to the paucity of her interior communications Persia has suffered considerably from the dislocation of her pre-war import and export routes, and from the consequent necessity of redistributing her foreign trade. Before 1914 the bulk of her imports entered the country through Enzeli and the Caspian ports, or via Trebizond and Tabriz. Detailed figures for 1921-22 show that only 8.4 per cent. of Persia's foreign trade passed through the northern countries adjacent to Persia, while 91 per cent. passed through the Persian Gulf Ports, Iraq or India. The figures for the following year will, it is believed, show no appreciable difference in the proportion of trade borne by these three countries, though the total amounts will not be the same, owing to the partial revival of the Trebizond route, in spite of the difficulties attending transport through the disturbed areas of Turkey, and to a slightly greater volume of trade by the Northern routes. In particular a service of small cargo steamers, with a capacity of approximately 800 tons of cargo each, has been started from Hamburg to Enzeli via the Russian canals and the Volga by a German firm. The first steamer reached Enzeli in November; 1922, but since that date no further steamers have reached Persian ports.

The cessation of a large proportion of the former trade with Russia has not been without effect in depressing the Persian market, and the closure of the northern trade routes has further contributed to this depression by enhancing the cost of transporting goods to North Persia which is often out of all proportion to their original cost. A few Persian merchants attended the Russian fairs at Baku and Nijni Novgorod which were revived last year, but most of the native trading community is without knowledge of conditions outside Persia, and except for the activities of the trading branches of the Soviet Government known as the Vneshtorg, Centro-Soyuz and Naftkom, no Russian agencies now cater for the export trade in such commodities as dried fruits which before the war were exported in large quantities to Russia and the Caucasus through Tabriz and the Caspian ports. Russian prints which in 1914 were universally known throughout Persia have also ceased to be imported in any quantity, and the northern markets remain relatively closed to trade, except so far as Russian petrol, kerosine oil, and similar products, are imported. Russia supplies her immediate needs by exporting rice and foodstuffs and a limited amount of timber through her commercial institutions and to some extent through Persian merchants in Gilan and Baku.

NEW TRADE ROUTES.

This alteration of Persia's normal trade routes has brought into prominence at least two routes which were rarely used before the war. The first of these is the Iraq route from Basrah via Baghdad to Kermanshah. This route was always popular with Persian traders before the war and the construction of the Iraq railways from Basra to Baghdad and thence to Quaniqin near the Persian frontier has increased the facilities for importing frail or perishable goods. The virtual closure of the northern trade routes has also contributed in no small measure towards making it for the present one of Persia's chief trade routes. Imports via Kermanshah which amounted to krans 190 million in 1921-22 exceeded in volume those of any other customs post in Persia, in spite of the 1 per cent. transit tax to which all goods passing through Iraq are subjected. In winter caravans leave the metalled road near Hamadan and make their way to Teheran via Sultanabad and Qum or direct via Nobaran in order to avoid the Aveh Pass north of Hamadan and the intense cold of the Kazvin plain. Imports via Iraq include in particular a large proportion of the Manchester piece-goods which are still imported in large quantities, although the return of the kran to its norml value and the competition of other European countries whose coinage has depreciated considerably has tended to restrict these imports and to cut the profit on their sale to a fine point.

The second trade route of importance is the Indian route entering Persia at Dalbandin by the Nushki-Duzdap railway. From a position of comparative importance owing to the gulf created between it and India by the Sarhad deserts Duzdap has since the construction of this railway during the war risen to be one of Persia's principal distributing centres. The foreign trade which used this route during 1922-23 reached a total of 87 million krans, an increase of 100 per cent. over the figures for 1921-22. The railway, besides tapping the rich grain districts of Sistan and the Kainat, now feeds the districts of Kerman and Meshed, and it is probable that a large proportion of the trade which used to reach Herat, and Trans-Caspia from Russia is now supplied from India by this route. Goods exported to Persia through India by this route are entitled to a rebate of fifteen-sixteenths of the customs dues paid on foreign imports into India.

BRITISH TRADE.

For the year 1921-22 the first five countries trading with Persia, in their order of importance were :—

	Imports.	Exports.	Total.
	Thousand Krans.	Thousand Krans.	Thousand Krans.
The British Empire, including India ...	462,100	159,000	621,100
Egypt	17,500	199,400	216,900
Russia	41,700	26,500	68,200
Iraq	8,300	44,400	52,700
U.S.A.	5,500	29 500	35,000

The British Empire, therefore, accounted for nearly 60 per cent. of Persia's trade, although it must be remembered that a certain quantity of the articles recorded by the customs authorities in Persia as coming from Great Britain or from India are certainly not of British manufacture or origin, but were merely consigned from these countries. This proportion has slightly decreased during the subsequent year, so far as can be ascertained, owing to a revival of trade with Italy, France and Germany in particular. The disparity between the import and export figures for the British Empire account for the depreciation of the kran on the British and Indian markets.

Persia's chief imports and exports during 1921-22 in their order of importance were :—

IMPORTS.

	Thousand Krans.
Cotton piece goods	188,600
Sugar	141,300
Nails, screws, iron piping, etc.	33,200
Tea	31,300

EXPORTS.

Oil and kindred substances, such as petrol, benzine, etc.	322,600
Carpets and rugs	66,100
Dried and fresh fruits	26,900
Opium	15,400

Imports during the year totalled 55 per cent. of the total foreign trade and exports 45 per cent. This ratio, so far as can be ascertained, remained virtually unchanged during the following year. Of the commodities quoted above, the British Empire during the same period supplied cotton piece goods to a value of 185 million krans and tea valued at 30 million krans, as well as almost the entire quantity of Persia's importation of nails, screws and iron piping. The chief sources of Persia's sugar were British India which supplied 67 million krans worth; Belgium, whence came 27 million krans worth; and Egypt, which supplied sugar to the value of 17 million krans. It is probable that a large proportion of the sugar supplied by India is not of Indian origin, since a certain amount is known to come from the Dutch East Indies and more is probably imported in the first place from France, Egypt and other countries for re-export to Persia via Duzdap and the Persian Gulf.

POTENTIAL WATER POWER IN NEW ZEALAND.

Estimates of the amount of available water power in New Zealand show a total of 4,076,700 horsepower, of which 759,700 horsepower is in North and 4,317,000 in South island. In the distribution of power resources, South Island is in an advantageous position, as the bulk of its potential supply is located near the deep water sounds of the west coast, where there are many sites suitable for electro-chemical and electro-metallurgical industries.

According to a report by the United States Vice-Consul at Wellington, a programme for water-power development has been prepared in which the chief sources of North Island will be utilised. These include Lake Waikaremoana, which has sufficient storage capacity to run the proposed generating plant for 21 months without rainfall, and the Waikato River project, which taps Lake Taupo. The first instalment will involve an estimated expenditure of £15,000,000 for the headworks, plant, and transmission line to Auckland and will develop 50,000 of the estimated 138,000 horsepower, which it is expected can be ultimately obtained.

State commitments up to the end of 1923 for the Lake Waikaremoana project amount to £110,000. By the end of 1924 it is proposed to spend £1,075,000, when it is expected that 24,000 horse-power will be available from this source. The method of financing hydro-electric development in New Zealand is chiefly through State aid, no projects of importance being promoted by private organisations. Southland Province, with some assistance from the State, is carrying on its development through a local body, the Southland Power Board.

Hydro-electric construction in New Zealand has been retarded by the high cost of financing, and if money were cheaper a tremendous impetus would be given to the carrying out of this project. It is recognised that the chief factor in the industrial development of Christchurch is cheap power, and among the farmers of North Island likewise a great increase in the use of small-power units would result from cheaper rates and an efficient system of distribution.

REVIVAL OF SILK INDUSTRY IN VALENCIA.

An intelligent and systematic campaign to revive silk culture in Valencia has been conducted recently, writes the United States Consul at that city. The result has been the planting of some 65,000 mulberry trees on 200 farms with about 1,000 individuals actively engaged in reviving silk culture in this district. The Government encourages sericulture by offering a premium of 50 centimos (normally 5d.) per kilo of cocoons. The worms producing these cocoons before being sold, must first be examined for disease and registered by a local branch of the Department of Agriculture, the containers of the worms being stamped and sealed by the authorities.

There are at present in Valencia some 400 looms for the weaving of various silk fabrics, such as damasks and brocades. These looms are operated by hand and all are modelled on the old ones used centuries ago. They vary in width from 1 to 3 metres. Most of the operatives are men highly trained in their work. The patterns used in the manufacture of damask and brocaded silks are almost entirely copies of designs from the seventeenth and eighteenth century. So cleverly are they copied that it is frequently impossible for the layman to distinguish between the old and the new. Many are in gold or silver thread. The dyeing is done in Valencia, generally by German dyers imported for the purpose.

These brocades and damasks range in price from 25 pesetas to several hundred pesetas per metre, depending on the design, colours used, and width. They possess considerable artistic as well as economic value. Comparatively little artificial silk is used in Valencia at present and the local manufacturers are doing their best to regain their reputation for silks of the highest grades.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

JANUARY 23.—G. ALBERT SMITH, "Cinematography in Natural Colours—further Developments" (with illustrations—scenes from H.R.H. The Prince of Wales's Tour in India). GEORGE E. BROWN, F.I.C., Editor of the *British Journal of Photography*, will preside.

JANUARY 30.—SIR RICHARD ARTHUR SURTEES PAGET, Bt., "The History, Development and Commercial Uses of Fused Silica." SIR HERBERT JACKSON, K.B.E., F.R.S., will preside.

FEBRUARY 6.—IYEMASA TOKUGAWA, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

FEBRUARY 13.—H. MAXWELL-LEFROY, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., will preside.

FEBRUARY 20.—PERCIVAL JAMES BURGESS, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

FEBRUARY 27.—CHARLES S. MYERS, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

MARCH 5.—MAJOR-GENERAL SIR FABIAN WARE, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries."

MARCH 12.—ALAN A. CAMPBELL SWINTON, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.)

MARCH 19.—R. L. ROBINSON, Member of the Forestry Commission, "The Forests and Timber Supply of North America." LORD LOVAT, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., will preside.

MARCH 26.—NEAL GREEN, "The Fishing Industry and its By-Products."

Dates to be hereafter announced :—

SIR LYNDEN MACASSEY, K.B.E., "London Traffic."

BRIGADIER-GENERAL SIR HENRY MAYBURY, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "Roads."

FRANK HOPE-JONES, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum."

J. ROBINSON, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MRS. ARTHUR McGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons at 4.30 o'clock :—

JANUARY 18.—COLONEL H. L. CROSTHWAIT, C.I.E., R.E., retd., late Superintendent, Survey of India, "The Survey of India." Sir THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, will preside.

FEBRUARY 15.—SIR RICHARD M. DANE, K.C.I.E., Commissioner, North India Salt Revenue, 1898-1907; Foreign Chief Inspector, Salt Revenue, China, 1913-18, "Salt Manufacture in India and China."

MAY 2.—JOCELYN F. THORPE, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced :—

BHUPENDRA NATH BASU, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons at 4.30 o'clock :—

FEBRUARY 5.—F. W. WALKER, "The Commercial Future of the Backward Races, with Special Reference to Papua." SIR GEORGE R. LE HUNTE, G.C.M.G., will preside.

MARCH 4.—THE HON. T. G. COCHRANE, D.S.O., "Empire Oil: The Progress of Sarawak." THE RT. HON. LORD BEARSTED will preside.

MAY 27.—C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

CANTOR LECTURES.

ERIC KEIGHTLEY RIDEAL, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." Three Lectures.

SYLLABUS.

LECTURE I: JANUARY 21.—Nature of Colloids. Properties of interfaces. Surface tension and adsorption. Decolourisation, gas absorption, stream line filter. The work of Hardy and Langmuir. Orientated adsorption, Catalysis, Enzmyes, Specific germicides, lubricants.

LECTURE II: JANUARY 28.—Suspension Colloids. Peptisation, protection and precipitation. Colloidal Mill. Electric cataphoresis and endosmose. Peat drying. Colloidal metals, Colloidal fuel, Ore flotation. Smokes, condensation of fumes, powdered fuels. Mists, Insecticides.

LECTURE III: FEBRUARY 4.—Emulsion Colloids. Preparation and Stabilisation. Coal tar disinfectants, Milks, Phase inversion-biological importance, greases, antigens. Soaps. Ionic micellae.

Adsorbing Gels. Silica gels, ferric oxide and alumina, clays, vaseline, rubber and textiles. Membranes, permeability. Equilibria at membranes, application to leather.

EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

COBB LECTURES.

Monday evenings, at 8 o'clock:—

DR. T. SLATER PRICE, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, JANUARY 14..Geographical Society, 135, New Bond Street, W., 8.30 p.m. Sir Alexander Kennedy, "The Rocks and Monuments of Petra."

Architectural Association, 34, Bedford Square, W.C., 8 p.m. Paper by Prof. A. E. Richardson.

Brewing Institute of, at the Engineers' Club, Coventry Street, W., 7.30 p.m. Mr. J. Stewart, "The Season's Barleys."

Charity Organisation Society, 296, Vauxhall Bridge Road, S.W., 4.30 p.m. Dr. A. Shadwell, "The Principles of Liquor Control."

TUESDAY, JANUARY 15..Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m. Mr. N. E. Crump, "The Inter-relation and Distribution of Prices and their Incidence upon Price Stabilisation."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. W. E. Dixon, "Drug Addictions." (Lecture I.)

Transport, Institute of, at the Institute of Electrical Engineers, Savoy Place, Victoria Embankment, W.C., 5.30 p.m. Mr. A. F. Bound, "Railway Signalling and its Development."

Asiatic Society, 74, Grosvenor Street, W., 4.30 p.m. Mr. Ayscough, "The Cult of the Spiritual Magistrate of the City Walls and City Moats."

Mineralogical Society, at the Geological Society, Burlington House, W., 5.30 p.m.

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Adjourned Discussion on "Superheating."

WEDNESDAY, JANUARY 16..Engineers, Junior Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.30 p.m. Inaugural Meeting. Address by Sir J. Fortescue Flannery, "Marine Propulsion during Fifty Years."

United Service Institution, Whitehall, S.W., 3 p.m. Rear-Admiral Sir E. P. F. G. Grant, "The Origin of the Overseas Naval Forces, their Organisation, Training and Relation to the Imperial Services."

British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. W. W. Davidson, "Stencils and their Uses."

Meteorological Society, 49, Cromwell Street, S.W., 7.30 p.m.

Transport, Institute of (N. Western Local Section), Manchester. Mr. H. Mattinson, "Passenger Transportation of Industrial Areas."

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15. Prof. F. S. Boas, "Childe Harold."

THURSDAY. JANUARY 17..Pottery and Glass Trades Institution, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.45 p.m. Mr. F. A. Perry, "The Art of Table and Domestic Glassmaking."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1. Mr. R. H. Atkinson, "A Suggested Explanation of the Allotropic Transformation of Iron." 2. Messrs. H. J. E. Dobson and I. Mason, "The Activity of Water in Aqueous Hydrochloric Acid." 3. Mr. J. R. I. Hepburn, "The Freezing of Inorganic Hydrogels."

Royal Institution, Albemarle Street, W., 5.30 p.m. Mr. W. Sickert, "Straws from Cumberland Market." (Lecture I.)

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. Mr. H. Marryat, "Electric Passenger Lifts."

Mechanical Engineers, Institution of (Local Section), Engineers' Club, Albert Square, Manchester, 7 p.m. Mr. I. H. Wright, "Recent Developments in Gears and Gear Cutting."

Economics and Political Science, London, School of. Sir Hubert L. Smith, "The Economic Laws of Art Production." (Lecture I.)

FRIDAY, JANUARY 18..Engineering Inspection, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Mr. F. Grove, "Reminiscences of Railway Work Overseas."

Medical Officers of Health, 1, Upper Montague Street, W.C. 5 p.m. Dr. M. Young, "The Public Significance of Mental Deficiency."

Royal Institution, Albemarle Street, W., 9 p.m. Prof. H. Armstrong, "The Scientific Work of Prof. Sir James Dewar."

Metals, Institute of (Local Section), University College, Singleton Park, Swansea, 7.15 p.m. Capt. L. Taverner, "The Annealing of Non-Ferrous Metals."

Geologists' Association, University College, Gower Street, W.C., 7.30 p.m. Prof. H. L. Hawkins, "The Wanderings of the Early Thames."

Engineers, Junior Institution of, 39, Victoria Street, S.W., 7.30 p.m. Mr. G. F. Tyler, "The Liability of Employers in respect of Personal Injuries to their Workmen."

SATURDAY, JANUARY 19..Royal Institution, Albemarle Street, W., 3 p.m. Mr. G. Reynolds, "Mechanical Reproduction of Music." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,713 VOL. LXXII.

12 FEB 1924

FRIDAY, JANUARY 18, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 21st, at 8 p.m. (Cantor Lecture). ERIC KEIGHTLEY RIDEAL, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." (Lecture I).

WEDNESDAY, JANUARY 23rd, at 8 p.m. (Ordinary Meeting). G. ALBERT SMITH, "Cinematography in Natural Colours—further Developments" (with illustrations—scenes from H.R.H. The Prince of Wales's Tour in India). GEORGE E. BROWN, F.I.C., Editor of the *British Journal of Photography*, will preside.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained by Fellows on application to the Secretary.

MANN JUVENILE LECTURE.

The second of the two Juvenile Lectures by Professor W. A. Bone, D.Sc., F.R.S., was delivered on Wednesday afternoon, January 9th. Mr. Alan A. Campbell Swinton, F.R.S., a Vice-President of the Society, presided.

Professor Bone referred to the researches, discoveries, and inventions of Sir Humphry Davy, George Stephenson, Michael Faraday, Smithells, Bunsen, and Welsbach. Davy's work he said, in nearly every particular, foreshadowed the whole of the progress which had been made during the last century. He taught us that to produce flame you must have an explosive mixture of gas or vapour and air, and that the mixture must be raised to a certain condition of temperature, called the ignition point. He compared Davy's definition of flame recorded in 1816 ("Flame is aeriform or gaseous matter heated to such a degree as to become luminous") with Smithells' definition made in 1916 ("The basis of flame is a glowing gas and the exciting cause, chemical action"). In making enquiries into the cause of the serious explosions in coal mines prevalent in those days, Davy discovered that methane and air only formed an explosive mixture within certain limits. This led to the invention of his miners' safety lamp, in which the flame was surrounded by gauze. The metal gauze cooled the flame in the cylinder down to below its ignition point. Examples of Davy's and Stephenson's lamps were shown, as well as a modern electric lamp, which would stand very rough usage. The devastating effect of a colliery explosion was vividly shown in a series of photographs taken in 1908, when an experimental gallery 200 feet long, composed of disused boilers, was erected on the surface. The interior of the boilers was utilised to represent as nearly as possible the actual conditions of an underground coal mine, and the force of the explosion of the fine coal dust and air was pictured on the screen.

There were a number of most interesting demonstrations showing the difference in the colour of a flame of hydrogen, carbon monoxide, and methane; the action of flame on metal gauze, as used in the safety lamp, and on a piece of asbestos paper; Smithells' separator apparatus; the structure of a candle flame and the three zones of non-combustion, partial combustion, and complete combustion; the action of the Bunsen burner and Welsbach's incandescent gas mantle which restored the luminosity taken away by the Bunsen flame; and the Meker burner. The explosive effect of the action of the Bunsen flame on a mixture of coal gas and air in a tin canister was shown. Another experiment illustrated the force of the flame when four tubes containing respectively 1, 2, 3, and 6 feet of carbon disulphide and nitric oxide were ignited, the largest tube being shattered into fragments. There was also a demonstration by means of a 14 feet tube of the different rates of speed of flame in various proportions of gas and air. Diagrammatic and other lantern slides were projected upon the screen showing a spectrum analysis of different forms of light; the direction taken by flames; the limits of inflammability; ignition ranges of hydrogen, carbon monoxide, and methane in air and in oxygen; flame speeds; an old-fashioned steel mill used to give light in coal mines before the safety lamp was invented; the rates of explosion in a detonating coil; the measurement of flame temperature; and the lecture concluded with a demonstration of the Radiophragm, a form of incandescent surface combustion, in which an explosive mixture of gas and air is burnt at a maximum rate of intensity without the production of any flame at all.

The Chairman proposed a hearty vote of thanks to Professor Bone and congratulated him upon the extraordinary success of his experiments and on the most lucid manner in which he had explained the subject of Flame.

Professor Bone expressed his thanks to the audience, and said a very large measure of the success of the experiments was due to the enthusiasm of his two assistants, Mr. D. T. A. Townend and Mr. S. Young, and he was very glad to see how much they were appreciated.

The meeting then terminated.

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES SECTION.

MONDAY, 17TH DECEMBER, 1923.

THE EARL OF AIRLIE, M.C., in the Chair.

THE CHAIRMAN said that he had great pleasure in introducing the reader of the paper, Mr. Noxon, Agent-General for Ontario. The province which Mr. Noxon so ably represented was perhaps, of all the provinces of Canada, one of the most suitable for British emigrants, and the first to avail itself of the facilities of the Empire Settlement Act. Mr. Noxon's whole heart was in the very important problem he would deal with that afternoon, and he (Lord Airlie) believed he was betraying no secret when he stated that Mr. Noxon was offered the appointment of Agent-General by his Government and accepted it with the special object of furthering British migration.

The paper read was:—

EMPIRE SETTLEMENT.

BY WM. C. NOXON,
Agent-General for Ontario.

It is not territory or material wealth that makes a country or an Empire great, but the quality of its people, and the principles underlying its civilisation. The greatness of the British Empire does not arise from the fact that it is an Empire upon which the sun never sets, or from the possession of its unrivalled Mercantile Marine, or from the protection of the British Navy. The greatness of the British Empire has its roots in the people of the British race, and it is the sap derived from British character which keeps green the leaves of the mighty British oak, under whose branches so many of the peoples of the earth have sheltered.

I would not be so presumptuous as to enlarge upon the past history of the British Empire to such a learned and patriotic Society as the Royal Society of Arts. You are all familiar with the lives and labours of the great Empire Builders of the past, who have handed down to us their priceless heritage.

You are familiar too, with the history of the British people. In this City of London, and this beautiful Homeland of yours, so rich in monuments of the past, it is easy to trace the birth and growth of our national consciousness, and of British institutions and British civilisation, from the days when Britain was a subject people under the yoke of the Roman Empire until to-day when we occupy, often so unassumingly, a leading place among the nations of the world. Who can measure or even imagine the pains and tribulations, the toils and fears, the strivings and setbacks, the battles and wars on sea and land, that have contributed to the steady and forward march of the British people through the centuries?

In this historic hall also, which I am so glad to know is now the property of the Royal Society of Arts, you have for many years heard from this platform and read in your *Journal* addresses and papers from men coming hot-foot to you from all corners of the British Empire, telling of the wonderful achievements of British Government and British civilisation in our own times. In looking over the list of these papers read to your Society since 1874, I have been amazed by the extent of the ground covered by these papers, and even by the extraordinary interest of their titles.

Familiar as you then are with the history of the British Empire, in the past, and with its glorious and beneficent achievements in our own times, I feel sure of a sympathetic response from you when I say that it seems to me a tragedy that in the British Isles, in the heart of the British Empire itself, there should be an honest man, of British blood, who has no prospects of finding work, or a British boy with no chance to learn a useful occupation that will give him a livelihood, or a young woman, capable and willing, and yet receiving the dole and living in idleness.

Surely in view of the fact that there are so many people in the United Kingdom itself who are without steady employment or satisfactory prospects in life, it does not seem necessary that the Overseas Dominions should go outside the British Empire for the new settlers needed to populate their empty spaces, and continue the development of their territories and natural resources. Whether viewed from the standpoint of present expediency or future safety, it seems to me that there is no problem before the Empire to-day so urgent and important as the problem of settling the empty spaces of the British Empire with the surplus population of the Motherland; and while it is primarily man-power that the Dominions want, I wish to emphasise again, and with all the force I can command, that man-power is not everything. It is *British* man-power the Dominions need.

It is a question how far it is safe to trust our ideals to the control of other nationalities. A close observer of affairs in the United States cannot help but be struck by the gradual submerging of their national ideals by the influence of an uninstructed foreign vote.

It has cost a very large sum both to parents and State to raise a healthy, sane, young Britisher and bring him to the point where he stands on the threshold of life. He is worthy of every consideration.

IS IT NECESSARY OR DESIRABLE FOR PEOPLE TO LEAVE THE UNITED KINGDOM?

Roughly speaking, the population of the United Kingdom is forty-five million, increasing at the rate of about one thousand persons a day.

In the year 1921 the excess of births over deaths in England and Wales was over one thousand a day. In 1922 it was still as high as 5,600 a week, and in the first six months of the present year it was 5,800 a week.

In England and Wales alone between 1911 and 1921, notwithstanding the enormous losses of the war, the population increased by 1,814,750. This is a much smaller increase than that of any other decennial period during the whole of the preceding century, and if the world were as settled as it was prior to the war, I have no doubt that England could take care of most of its greatly increased population.

The figures relating to the density of the population of the countries within the Empire are certainly very significant, and, if I may be permitted to say so, somewhat disquieting. In fact it is estimated that the total white population within the Empire is about sixty-five million, and as forty-five million live in the United Kingdom, it is quite evident that other parts of the Empire are not over supplied with British stock. For example:—

	Persons to the square mile.
Great Britain has	482
New Zealand has	12
The Union of South Africa has ...	3
Canada has	2
Australia has	2

There is no country within the Empire, or out of it so densely populated as England with 700 persons to the square mile.

	Persons to the square mile.
Germany has	329
The Netherlands	554
Belgium	636
Italy	337
Japan	215
Ireland	138

He would be a bold man who would say that there is nothing wrong in England having 700 people to the square mile, and Canada and Australia only two or three people to the square mile. My own view is that this glaring inequality of the distribution of the population within the Empire lies at the very root of some of the very serious social and economic troubles from which England is at present suffering. If you over-crowd a railway carriage or a house, the occupants are discontented; if a country is overcrowded to the degree where there is not enough work to go round, and where many find it impossible to make any headway at all, the general standard of life is lowered, and there is sure to be discontent and unrest.

We might divide the United Kingdom population into four classifications: 1. Those engaged in agriculture; 2. Those engaged in industrial occupations; 3. Those engaged in clerical and professional occupations; 4. The juvenile and the unemployed.

Prior to 1914 the United Kingdom was the source of supply to different parts of the Empire, and to the United States in particular, of skilled artisans. It was also the source of supply for a considerable amount of unskilled or casual labour; also agricultural workers, domestic servants and clerical and professional people. In fact, the demands of high class occupations in the different parts of the Empire and in other countries, particularly the United States, were sought for in the United Kingdom.

The ever-growing population of the British Isles has always provided an overflow of emigrants, and this fact no doubt has contributed very materially to keeping the balance between the population of the country and the requirements of its industries.

But to-day we are faced with this fact, that not only is the population of the country increasing at the rate beyond the absorbing power of its industries, but emigration is to-day operating on a very restricted scale as compared with before the war. The following table illustrates this state of things:—

MIGRANTS OF BRITISH AND IRISH NATIONALITY.

Year.	Outward.	Inward.	Balance.
1913	389,394	85,709	303,685
1921	199,477	71,367	128,110
1922	174,096	68,023	106,070

The following table shows the destination of those emigrants who have settled within the Empire:

Year.	British North America.	Australia.	New Zealand.	British South Africa.	To other Parts of Empire.	Total British Empire.
1913	190,854	56,779	14,255	10,916	12,242	285,046
1921	67,907	27,751	11,513	12,903	16,703	136,777
1922	45,818	39,099	12,259	8,772	12,462	118,410

WHAT HAS BEEN THE INCREASE IN POPULATION TO THE SELF-GOVERNING DOMINIONS BY EMIGRATION?

Of course, the figures of the numbers of people leaving this country for the Overseas Dominions do not tell the whole story. The movement of people from the Dominions must be taken into account. This information is not always very easy to discover, and as regards Canada accurate information regarding emigration—that is the number of people leaving Canada for the United States and elsewhere—has not yet been made available, and to that extent Canada's vital statistics are incomplete.

The movement of population from some parts of Eastern and Central Canada to the United States has been notorious for generations past. On the other hand the influx of United States farmers into Western Canada has also been on a very large scale.

It is rather curious to observe that the total number of immigrants entering Canada between June 1st, 1911, and June 1st 1921 (the dates of the last two censuses) was 1,812,836; the total increase of population between those dates was only 1,581,840.

This is all the more strange when one remembers that Canada enjoys a fairly large natural increase of population, namely, an excess of births over deaths.

NEW ZEALAND.

The figures relating to New Zealand show the following as representing the excess in the number of arrivals in New Zealand from the United Kingdom over departures from the Dominion to the United Kingdom:—

Year.	Net excess of arrivals over departures.
1909	8,508
1910	6,858
1911	8,624
1912	10,307
1913	12,058
1914	6,005
1915	1,468
1916	786
1917	1,430
1918	731
1919	1,109
1920	8,345
1921	approximately 9,629
1922	7,604
Total	83,462

AUSTRALIA.

The official Australian figures with regard to net immigration are very complete. These show that during the period 1861-1921 —*viz.* 61 years—the gain to the Commonwealth population by excess of arrivals over departures was only 1,030,855 persons, while the gain by excess of births over deaths during the same period was 3,333,789.

The following details are also available :—

Five year periods.	Net gain by excess of arrivals over departures.
1876 to 1880	130,142
1881 to 1885	224,040
1886 to 1890	158,701
1891 to 1895	22,392
1896 to 1900	2,487
1901 to 1905	loss 16,793
1906 to 1910	57,278
1911 to 1915	99,393
1916 to 1920	71,133
1921	15,789
Net gain	764,562

The above figures—not only in the case of Australia, but also as regards Canada and New Zealand—indicate that one cannot judge the migration movement solely by the figures which give the number of emigrants who leave the United Kingdom.

They also indicate very clearly that emigration will have to be increased to a very considerable extent yet before the problem presented by the over-populated state of the United Kingdom and the under-populated conditions of the overseas Dominions is within measurable distance of being solved.

WHAT IS THE PRESENT OUTLOOK ?

There are less than three million of the population in the United Kingdom engaged in the pursuit of agriculture, and this includes auxiliary occupations such as domestic servants, gardeners, cattlemen, horsemen, gamekeepers, overseers, etc., and it is estimated that they produce from 25 to 30 per cent. of the country's food requirements.

It is also estimated that there are some fourteen millions of the population engaged in industrial work, and at least a portion of the product of their effort requires to be sent abroad to help purchase the unprovided food requirements.

HOW HAS THIS HERETOFORE BEEN ACCOMPLISHED ?

I believe it reasonable to assume that a good deal of British commercial greatness has come about from the world's confidence in British commercial justice. It might be said that England's export trade rested upon four main foundations :—

1. Cheap coal; perhaps the best coal in the world, and for home consumption one of the cheapest, and therefore one of the greatest factors in industrial activities.
2. Cheap and plentiful supply of money, not only sufficient for home requirements but sufficient for enterprise abroad, which naturally carried export trade.
3. A plentiful and cheap supply of good food. This meant reasonable wages.
4. Perhaps the most important of all—the control of the mercantile marine of the world, which to a great extent set the cost of transportation.

With these four advantages England was able to meet throughout the world the competition of other nations who possessed different advantages.

WHAT IS THE SITUATION TO-DAY ?

1. The country has still good coal, but not cheap as compared with before the war.

2. The country has still a reasonable supply of capital for home requirements, but little, if any, for outside enterprise, and capital is not as cheap as before the war.

3. The country has an ample and good supply of good food, but not cheap as compared before the war.

4. Instead of having cheap transportation the country has about the dearest water and rail transportation it has ever experienced.

Thus, nearly every favourable condition has been reversed.

NOW LET US LOOK AT THE MARKETS.

Before the war England's chief export value was in coal, and in my judgment this will continue to be the chief export value. This can hardly be called an industry.

It has a labour value, and is a diminishing asset. Every ton taken out of the mine leaves a ton less there, and each succeeding ton costs a trifle more than the preceding one.

The best markets for English industry were in the near and far East, in Europe and in the Americas, and the Empire Dominions.

WHAT IS THE CONDITION OF THESE MARKETS TO-DAY ?

During the war Japan and the United States succeeded in obtaining a fair footing in the Near and Far East, and they are still there.

Moreover, India in particular has become a self-governing Dominion to a great extent, and has the authority to establish tariffs, which she has already done.

Thus, British commercial influence in the Near and Far East is not likely to be any greater than it was heretofore, if as great.

Take Europe, I think we shall all admit that the present generation will not see Europe sufficiently established to be the customer she was before the war.

Then take the Americas, and the self-governing Dominions. In all cases evidence goes to show that it is the desire of these countries to make more of what they need, and sell more of what they do not require. Under these circumstances one fails to see just where this country is going to establish new or increasing markets for her surplus products of industry, which is absolutely essential to her economic life. It is therefore reasonable to argue that some distribution of the ever increasing population is not only desirable but practically necessary.

WHY PEOPLE DESIRE TO EMIGRATE.

The first instinct of life is material self interest. A man says: "How am I going to live, and how am I going to live a little better or a little easier ?" and thus, wherever the outlook appears to be the best from his view-point the magnet is likely to be the strongest.

The facts and figures which I have quoted in this paper prove, I think—

1. That it is desirable in the interests of the Motherland, and also in the interests of the Overseas Dominions, that a redistribution of population should be effected as far as possible.
2. That this migration from these over-populated Islands to the under-populated parts of the Empire is not at present proceeding at anything like the rate that is necessary and desirable.

Before proceeding to consider the best methods to adopt to have this condition of things righted, let us first consider very briefly the reasons and circumstances which induce people to migrate.

The first observation I would make is that the successful, the well-to-do, the contented, and those having strong-family ties, do not migrate. They are the backbone of the country. On the other hand, those who are infirm, who are aged, who are sub-normal physically, mentally, and morally, must remain in the country of their origin. Therefore, the middle line is the only one available, and this is a general average of the people. We must take into consideration that there are four distinct elements which encourage emigration :—

1.—*Ambition.* In other words, the man who finds insufficient elbow-room for his personal ambitions, or who has a marked interest in the success of his family, studies the opportunities of various countries as compared with his own before he decides where he will go. Boundaries of countries have very little deterrent effect in keeping an ambitious man from going to the place where he believes his experience and ability will earn him the best returns.

2.—*Adventure.* This is an impulse which induces migration. It is characteristic of British people. They like to see the world.

3. *Uncomfortable,* unpleasant, unhappy and unsatisfactory local economic or domestic circumstances. These themselves induce separation. Dissatisfied people are naturally inclined to emigrate.

4.—*Need.* From this source comes all dependent child migration.

The greatest obstacle to an increased flow of people from this country to the self-governing Dominions is a lack of knowledge of living conditions and opportunities in the Dominions. Within the last two weeks, and within a distance of ten miles from where we are assembled, an Englishwoman of more than ordinary intelligence asked a chemist if California belonged to England, and his reply was: "I have really forgotten what country California belongs to."

I have given you a great many statistics, because statistics have a certain interest and moreover comparative figures are necessary to show how we stand. I desire to say very emphatically, however, that the problem of Empire Emigration will never be solved by Statistics. When you are dealing with human beings, the part which Statistics are able to play is generally a small one. Human nature has a habit of ignoring figures altogether, and self-interest cannot be turned from its purpose by the most formidable array of statistics ever compiled by Government offices.

In dealing with the subject before us, one often hears it stated that there is plenty of room in the Overseas Dominions. So there is. But do not forget that there are other things there besides vacant spaces. There are people there already, people of British blood, it is true, and proud of belonging to the British race, but nevertheless, people who have an even greater pride in the land of their adoption, whether it be Canada, Australia, New Zealand or South Africa.

The people of these young nations across the sea have their own national tradition, which is in a sense a thing apart from the common traditions of the British race. They are well versed in the history of the land of their adoption. Australia and Canada and New Zealand—and may I add even Ontario—have their own national heroes, men who are as important to them as your Nelson or Wellington, but whose names are quite unknown in England. The people who live in the Overseas Dominions know the story of their national life from its earliest beginnings, and they know the heroism, toil and perseverance of the pioneers who built their adopted country from the point when there were only a few log houses in the backwoods.

It goes without saying, therefore, that the people of the Overseas Dominions have very strong opinions regarding what is best for their own countries. They know the needs of their country better than anyone else can know them. And when it comes to a question of framing an immigration policy for the country they are living in, they naturally insist that that policy must be in keeping with their requirements.

To put it bluntly, the Dominions will not and cannot undertake to receive all the surplus population of the Motherland, irrespective of their suitability for the conditions existing in these newer lands. They are only able to absorb certain classes of people who will fit in naturally with the process of their development.

So when you hear it stated that there is no need for anyone to remain unemployed in Great Britain because the Greater Britain beyond the seas has room enough and to spare, you may take it that although such a statement may sound well, it is not practical politics.

THE KIND OF PEOPLE THE DOMINIONS WANT.

Speaking generally, the classes of workers which the Overseas Dominions can absorb, and whom they are prepared to welcome in large numbers, are as follows :—

(1.) Young women for household work;
(2.) Experienced farm labourers, both single and married;
(3.) Lads and young men who are inexperienced in farm work, but who are prepared to take employment on farms;
(4.) Farmers with capital;
(5.) People who can pay their fares, and are going out to friends already settled overseas;
(6.) People who have capital to invest in business, and later we hope skilled artisans.

ASSISTED PASSAGES UNDER THE EMPIRE SETTLEMENT ACT, 1922.

Since the passing of the Empire Settlement Act, 1922, the British Government has entered into agreements with various Overseas Governments for the provision of assisted passages to help forward suitable migrants, and already many thousands of people have been successfully settled overseas. Several Governments supplement these with assisted schemes of their own.

The following is a summary of the schemes of assisted passages in operation :—

Canada.—Assisted Passages by way of loan (full passage money if required) to approved women household workers. As regards men, people in Canada who can guarantee work on the land for a friend in Great Britain or Northern Ireland, may nominate such person for an assisted passage. The nominator must advance 25 per cent. of the passage money, and the remaining 75 per cent will be advanced as a loan by the Governments of the United Kingdom and Canada. Children (boys up to 17 and girls up to 14) who are approved and whose care and settlement are undertaken by institutions such as Dr. Barnardo's Homes, the Liverpool Sheltering Homes, etc., are carried to Canada free, 50 per cent of the passage money being paid by the British Government and 50 per cent. by the Government of Canada.

Ontario.—The whole passage money is advanced as a loan where necessary to approved women household workers. Assistance up to £18 is advanced as a loan to single experienced farm workers. In the case of both men and women the Government of Ontario guarantee employment at good wages on arrival.

New Zealand.—Free passages, plus £2 bonus, are granted to approved experienced household workers and the passage money has not to be repaid. Also passages at reduced fares to skilled single farm workers and a few married workers without families, the cost of passage being £11 per person. For persons nominated by friends in New Zealand, passages at reduced fares are available, and, where necessary, loans are granted to nominated passengers who are unable to pay the reduced fares.

Australia.—Women domestic workers are granted loans towards the cost of the passage in whole or part, if approved. Farm workers, and also manual workers who are not experienced in farm work, and who are single, and also married men who can go in advance of their families may receive a free grant of one-third, and if necessary, a loan up to the remaining two-thirds of their passage money.

All the Australian States will take boy farm learners from 15 to 18 years of age, and guarantee them situations with farmers at wages ranging from 7s. 6d. to 20s. a week, with board and lodging in addition. They are regarded as apprentices for from one to three years.

Assisted passages are granted to these boys under the Empire Settlement Act.

Western Australia.—There is a group settlement scheme in this state whereby experienced and inexperienced married men may take up free land and draw sustenance allowance during the preparation of the new home. Long-term loans are granted to such settlers to facilitate the development of their properties, and housing accommodation is provided at the outset by the Government of Western Australia.

Victoria.—Single men and married men with families who can deposit with the Government a capital of at least £300 will, if approved, be assisted to settle on farms of their own in Victoria and loans are granted for stock and equipment.

WHAT THE EMPIRE SETTLEMENT ACT SCHEME HAS ACCOMPLISHED.

Up to October, 1923, the number of people who have been taken from Great Britain and placed overseas under the auspices of the Empire Settlement Act, has been 37,205.

The cost to the British Government, a good deal of which may be recoverable, has been £400,000.

The number of assisted passages granted during October, 1923, in connexion with agreed schemes under the Empire Settlement Act and the total number of such passages granted from the inception of these schemes, together with the numbers of departures during the same periods, are shown in the following table :—

	Assisted passages granted in October 1923.	Total assisted passages granted.			Total. Departures.	
		1922	Jan.-Oct. 1923.	Departures in Oct. 1923.	1922.	Jan.-Oct. 1923.
Assisted Passage Schemes						
To Australia	2,123	7,058	23,659	2,591	6,118	19,952
To New Zealand	794	1,133	5,409	512	694	4,365
To Canada						
Dominion of Canada	495		3,443	478		3,344
Province of Ontario............	54		1,681	67		1,309
Minor Schemes................	113		1,531	113		1,468
Total	3,579	8,191	35,723	3,761	6,812	30,438

The figures given in the above table include both applicants and dependents of applicants to whom assisted passages have been granted. The discrepancy between total assisted passages, 35,723, between January and October, and total departures—30,438 — during same period, is due to the fact that some people dropped out at the last moment and others have deferred their sailings until the spring.

There is no doubt in my own mind that the idea behind the Empire Settlement Act, namely, the granting of assisted passages to suitable men and women in order to enable them to go to other parts of the Empire where they will find assured employment and better prospects of life, is an excellent one.

As a matter of fact, under present conditions men of the farm labouring class and domesticated young women who wish to take up household work, would have no chance at all of ever getting to Canada, Australia or New Zealand unless it were made possible for them to obtain loans covering practically the whole cost of their passage money.

I was speaking to a very experienced Shipping Agent the other day—a man who has been in business in Norfolk for many years—and he told me that practically every day he interviews about 20 or 30 men and women who come to his office anxious to find out how they can get to one of the Overseas Dominions, and in practically every case my Shipping Agent friend finds that these people are without funds.

The various schemes which the British Government have entered into with the Governments in other parts of the Empire for the purpose of granting assisted passages and undertaking the settlement of suitable people are, as far as my knowledge goes, working satisfactorily.

The wages ruling in all the Dominions for all classes of workers are generally speaking considerably higher than the wages obtainable in England.

All emigration as now carried out by the various Governments of the Overseas Dominions is thoroughly well organised. The days when people were taken to a new country and left to sink or swim when they got there are past.

There is a large demand for experienced household workers in all the Dominions, not only in the cities, but on the farms as well, and I am certain that we can continue for many years to come to settle satisfactorily many thousands of girls in such situations where they will obtain higher wages than they would be likely to obtain in England, more liberty, a fuller and freer life, and better prospects generally than was their lot in this country.

The farm homes of Ontario, as is likely in the other Dominions, where girls are wanted to assist the farmer's wife with the house work, are quite equal to the farm houses in England as regards comfort and convenience, and very much better than the generality of farm houses in Scotland and Ireland. Many of these farm houses in Ontario have electric power for all purposes.

The Soldiers' Settlement Board of Canada.

Over 27,000 ex-soldiers have been settled on farms of their own in Canada under the auspices of the Soldiers' Settlement Act of Canada, 1919. Up to the end of 1922 the Canadian Government had advanced 88 millions of dollars for this purpose. More than 25,000 of the ex-soldiers so settled were heads of families, and it is estimated that by this means 100,000 people, men, women and children have thus been added to the permanent agricultural population of Canada. In all 4,854,790 acres of Canadian land has been occupied by ex-soldiers under the scheme.

Of special interest to Great Britain is the fact that Imperial ex-service men are eligible for participation in the benefits of the Soldiers' Land Settlement Scheme of Canada. The scheme provides for the granting of loans by the Canadian Government to settlers as follows :—

1. To purchase land up to 4,500 dollars.
2. For stock and equipment up to 2,000 dollars.
3. For permanent improvements up to 1,000 dollars.

Loans are repayable in 25 consecutive annual instalments, five per cent. interest being charged.

If an applicant from Great Britain has practical farm experience in Great Britain, he is required only to be able to pay down in cash twenty per cent. of the amount involved in the purchase of the land, stock, and equipment he desires. If he is able to pay fifty per cent. of the sum required, agricultural experience is not insisted upon.

Applicants who have had at least two full years' farming experience in Canada, or one year in Canada and one year elsewhere are only required *to pay ten per cent. in cash at the time of the purchase of the land,* and no initial cash payment is required on stock and equipment.

Building up the Empire

The British Empire, as it is to-day, has been built up by migrants from the old country who have left their homes, in some cases from a desire for adventure, and in other cases under the pressure of economic necessity, and have rooted themselves in the soil of distant lands under the British flag. It goes without saying that both in the interests of the mother country and in the interests of the Overseas Dominions, it is highly desirable that migration within the empire should continue. In fact, it seems to me that under the conditions in which we now move it is even more necessary than it ever was in the past.

I would be the last person in the world to try to persuade anyone in this country to migrate, even to my own native Province of Ontario, which I believe in my heart is one of the most fertile, progressive and prosperous countries in the whole world, but persuasion is not necessary in connexion with Empire migration. The migratory instinct is as strong to-day in many men and women of British blood as ever it was. There are tens of thousands of people—I might say hundreds of thousands—in this country to-day who would give almost anything for a chance of bettering themselves in some of the new countries of the Empire, but these people are unable to move unless they can be assisted. It was with the object of assisting such people who can be naturally absorbed by the Overseas Dominions that the Empire Settlement Act was placed on the Statute Book, and I can say most sincerely that in looking around I can see no better way in which public money can be expended than in the promotion of organised migration within the Empire to the fullest extent that is found practicable.

Have the people in this country stopped to think whether or not they are making of their young the finished product which the Overseas Dominions and other countries have heretofore so keenly sought after ?

Does the present form of labour permit sufficient young people to be incorporated as apprentices to supply not only the future needs of this country but the future requirements of other parts of the Empire ?

Is the country preparing domestic workers of a quality and in numbers to meet the demands of the other Dominions ?

Is it not necessary that this country should look ahead and try and equip the young with qualifications which will insure them a livelihood in other parts of the Empire ?

From a business standpoint it is estimated that the United Kingdom sells goods to the Dominions to the extent of £5 per capita, and to the outside world to the extent of five shillings per capita. At a glance, therefore, how evident it is that a better distribution of the population to the Dominions within the Empire would increase the demand for goods from this country, and thus stimulate production and lessen unemployment.

The phrase " British possessions " might also be transposed into the phrase " British Empire partners," all with a harmonious co-operation towards a common Empire interest, with the spirit of good-will and forbearance, believing that what is good for any one part of the Empire is good for the whole. A case of—

" ONE FOR ALL, AND ALL FOR ONE."

DISCUSSION.

THE CHAIRMAN (Lord Airlie) said that the Society was very much indebted to Mr. Noxon for a valuable paper. There were one or two points which he, as a member of the Oversea Settlement Committee, would like to emphasise. Mr. Noxon had pointed out the desirability of peopling the vast empty spaces of the Empire and developing our Imperial heritage by means of new settlers from this country who would bring with them the old British traditions and sympathies. He had given them significant figures as to the density of population in this country and the sparseness of the population overseas. In all that he had said on that point they were entirely at one with him and it was the realisation of this position which had led the Governments of the Empire to embark upon a policy of State-aided emigration and settlement for the benefit of the British Empire as a whole and of all its citizens. This policy had been embodied in the Empire Settlement Act under which a sum of £3,000,000 a year for 15 years was available for that purpose. The reasons for the inauguration of this new policy were obvious. The war cut across all the old currents, and in particular entirely stopped emigration to foreign countries and migration within the Empire. It was necessary to re-start this flow, and in existing conditions State aid was a necessary part of the process. They must all help to distribute the population of the Empire to the best advantage, and in doing that they must try to overcome the drift towards cities and industrialism. It was easier to do that oversea than in this country because oversea the land and other facilities for settlement were in existence in such abundance. The problem was to bring the landless man to the manless land. It was regrettable to think that there were over the whole of the British Empire fewer people engaged in agricultural pursuits than there were in France. He was glad that the author had emphasised the point that by developing the Empire we developed our best markets. It would take time to restore our European markets. In the meanwhile it was wise to pursue a policy of developing our Empire and calling upon the new world to redress the balance of the old. The critics in this country often stated that migration took away our best. On the other hand, the critics in the Dominions often said that we in the old country only gave them our worst. He thought that probably the truth lay somewhere between the two, and that the Dominions got, on the whole, a good average Briton. This was after all as good as, if not better than, the best of any other nation in the world. He was glad, furthermore, that the author had laid stress upon the point that migration must not be regarded as the means of remedying any abnormal unemployment in this country. It did, of course, relieve unemployment, inasmuch as the men who were unemployed here obtained employment overseas, but a larger view of the problem must be taken, and they must all look forward to the time when, by the redistribution of the population of the Empire, it would be possible so to stabilise economic conditions that unemployment within the Empire would be a thing of the past. The author had spoken of the migration of boys. As a matter of fact the Oversea Settlement Committee regarded juvenile migration as one of the most promising forms of migration. Youthful migrants settled down much more readily and easily than those of mature years. It was like planting trees ; a young tree more readily took root than one that was old, which perhaps never took root at all. He hoped that very shortly it would be possible to arrange with Mr. Noxon's Government a scheme for the settlement of boys from this country under particularly favourable conditions. In other parts of the Empire too the Committee was negotiating schemes for the settlement of boys both from our public and secondary schools. Last, but not least, there was the question of the migration of women. Quite apart from the fact that at the present time in this country there were considerably more women than men, they felt that everything possible ought to be done to stimulate the settlement of women in the Dominions if they were to make those British homes overseas, which were, after all, the only sure basis of permanent British settlement.

Lieut.-Colonel J. Obed Smith, Superintendent of Emigration for Canada, said that the question of migration had many sides to it and was one so full of detail that he was afraid that if Mr. Noxon or himself attempted to deal with only a few of the outstanding points they would be there all night. He appreciated the concise and forceful statement which the author had made on the general question, and he would like to add, for the comfort of those who were perhaps alarmed at the smallness of the figure quoted for State-aided emigrants, that while only 5,000 had received assistance under the Empire Settlement Act during the same period not less than 60,000 had paid their own passage. It was to no criterion of what the Act had achieved or could achieve to say that only 5,000 had gone to Canada since the 1st of April, 1922. He would like to speak of the migratory desire of the people in this little old land. He thought that he knew something about it after his own forty-two years' experience. His mind was not too old nor too young to realise that the great colonisers of this Empire, the men who left these shores sometimes not knowing whither they went and sometimes caring even less, went out desiring only one thing, and that was to carry to the uttermost parts of the earth the Union Jack and to colonise those parts with British stock. He thought of Captain Cook, in the Southern Seas, of Hudson, in the Northern Seas, and of many other great names in the wonderful history of the British people. Somehow he felt that the people nowadays had lost something of that sterling spirit which induced these men to give up the comforts of home, all the softness of existence, and go out for the sake of that greater and wider purpose, the fulfilment of which had meant so much to this island and this Empire. He had said once before, and he was rather fearful of saying it a second time, but he did say with all diffidence, that if people would realise that the Governments Overseas were really putting forward their very best efforts, aided by such organisations as the Salvation Army, the Church Army and others, and were spending enormous sums of money on both sides of the Atlantic to encourage people to go out and to place them properly on the land when they got there, the situation would acquire a new aspect. He believed it to be the fact, however, that the colonising spirit of this island had largely died away. Was it the modern conditions of labour, unemployment insurance or the "dole" which was causing it ? It did seem to be the fact that the young people were not willing to go out and take their prospects in thier own hands and do their best Overseas. In saying this he was casting no reflection upon the young people in this country which he did not cast upon the young people in Canada, where he knew it was often the ambition of the man in college, for instance, simply to have a motor car. In the old land people seemed more willing to stay at home than to carry the flag Overseas. But surely in view of what was done in the war to kindle the imagination of the British people and to incite a nobler spirit among them, it was not going against human experience and endeavour to rekindle also the spirit of enterprise and adventure which in years gone by had made the Empire what it is.

Commissioner D. C. Lamb (Salvation Army) said that he had listened with great pleasure and profit to the paper, but he did not find himself in entire agreement with all that the author had said, nor indeed with what Colonel Obed Smith had said. He had been trying to look at this problem from the point of view of a would-be emigrant, and also from the statesmen's point of view—not the politicians'—and, with the Chairman's permission, he would run through a few rather disjointed observations. It was very necessary in this Empire—this great Empire on which the sun never set—to find out where the people could be put, and to put them there. From the statesmen's point of view, a very important question was that of agriculture. It might be true that men had been hanging on in this country because of the "dole," and that the agriculturists had been hanging on with the hope of a dole also. But, generally speaking, if this country were called upon to settle whether there should be a dole or a big Navy, it would stand out for the big Navy every time. The author stated that if the world were as settled as it was prior to the war he had no doubt that England could take care of most of its greatly increased population. The speaker begged Mr. Noxon's pardon for describing that statement as nonsense. The normal overflow before the war was 350,000 people a year. Now, with the more enlightened public opinion which had arisen since the war, that figure of 350,000 would increase because people knew that there were better conditions for the bulk of them Overseas than there were at home. That was a factor which it was of no use to disguise. Then the author said that there was a demand for the settlement of these people within the Empire. But he (Commissioner Lamb) was of opinion that the English-speaking people had a destiny also which was outside the Empire, and in the case of many people, when it came to a question of bread and butter, they were not going to be confined necessarily to the Empire. In saying this he was not speaking only of Scotsmen. Then he had to pass to something which was rather unpleasant and disquieting. He referred to the population of Canada itself. He had spoken freely to his Canadian friends on that subject and he hoped that they would have a little more courage than they had had in the past, and face the question of their own vital statistics. The author had stated that in the decade 1911-21 the total increase of the Canadian population was 1,581,000, yet the increase by migration showed 1,728,000. The position was even worse than was conveyed by those figures. Those of them who knew Canada were aware that the bulk of the natural increase had been in the province of Quebec. That was notorious. Outside Quebec families were nothing like so large. What was the condition of the other provinces? It was a condition that called for statesmanlike capacity. There was a serious depopulation going on in Canada outside the province of Quebec. Then there was the question of the foreign element. He could assure them that the foreign element was all right. He had seen the foreigners in Canada going to church or engaging in business in the market places, and they were just as decent and honest as anybody else. The foreign element was all right, but these people did not speak our language. They had to be impregnated with British sentiment. He hoped that the Western provinces especially would have the attention of those responsible for Empire Settlement. He was afraid that the author was in a pessimistic vein when he said:—"Take Europe, I think we shall all admit that the present generation will not see Europe sufficiently established to be the customer she was before the war." He (Commissioner Lamb) hoped that they were going to live long enough to see a more stable condition of affairs than existed at present. After all, the world in these days moved quickly, and once people got seized of the fact that the moral issues were greater than the economic issues a vast improvement would take place. It was time that they all had more concern about moral issues, and let the economic issues adjust themselves to the moral issues. Then he had another grouse at the paper. The author had written:—"The greatest obstacle to an increased flow of people from this country to the self-governing Dominions is a lack of knowledge of living conditions and opportunities in the Dominions." That sentence would have to be revised. They were now emigrating people at the rate of 5,000 a week. He, for his own part, would guarantee to find 5,000 a day, starting from January 1st, the people being up to the standard required, if only the Dominion Governments would agree to look after them. The author further stated that when one heard it said "that there is no need for anyone to remain unemployed in Great Britain because the greater Britain beyond the seas has room enough and to spare, you may take it that although such a statement may sound well, it is not practical politics." He would like to know why. He would also like to make a reference to the scheme, mentioned by the author, of nominative passages to Canada. The nominator advanced 25 per cent. and 75 per cent. was advanced by the Governments of the United Kingdom and Canada. Wonderful Governments! But this was on the guarantee of repayment by the nominator. The Governments were taking no risks!

MR. F. C. WADE, K.C., Agent-General for British Columbia, said that he had known the author long enough to be sure that when he tackled any subject he would do so in a thorough-going way. Already in the discussion they had had the advantage of hearing two great authorities on the question of migration—Colonel Obed Smith and Commissioner Lamb. He was rather inclined to Commissioner Lamb's view on many questions. But they could not blame Colonel Smith, Mr. Noxon or anybody else because migration was not as great a success as it should be. The fact was that migration from this country was less of a success almost every year. They had talked much about the Empire Settlement Act. That Act started off with a magnificent flourish; it was to help people in this country to settle in the expanses of the country Overseas. We were spending 100 millions sterling every year on doles; how much were we prepared to spend on emigration? Three millions a year! Several years had gone by since the Empire Settlement Act was adopted. Had this country been spending even three millions a year? Had the intention of the British House of Commons been carried out? He believed that the amount spent had actually been somewhere about £400,000. Had the law, then, been defeated in its administration? An arrangement had been made lately with regard to the cattle embargo, which arrangement had been repeatedly defeated. Was the House of Commons being defeated again in this question of emigration? Had Colonel Obed Smith arrived at the proper solution when he said that we had lost that old "wanderlust" which used to characterise this great people, or was there some other reason for the default?

Then they had been told about the Soldiers' Settlement Act of Canada, under which Act great things had indeed been accomplished so far as Canadians were concerned. Under the Empire Settlement Act, the man when he got to Canada was offered a loan of $4,000 for one purpose and a loan of $2,000 for another. That was a most munificent offer, but why had it not been taken advantage of by the retired officers and other men who had served in the war? Why had "Tommy" not taken advantage of it to go to the new country? The soldier had been abroad all through the war. It could hardly be lack of adventure that kept him at home now. What was more likely to keep him at home was the provision that he had to advance 20 per cent. of the cost. That defeated the method at once. What the speaker proposed some time ago was that if the Imperial Government in London would read these two Acts together, and not separately, it would be greatly to the advantage of all concerned. He understood that the extreme provision payable to the civilian under the Empire Settlement Act was £300. Why could not they say to the ex-soldiers: "We will let you have that £300, and with that you can pay your 20 per cent. of the cost"? If that were done, very soon all the officers and men who wanted to go to the Dominions would offer themselves. But the two Acts were separate things and no attempt was made to reconcile them. Could the great propaganda of emigration from this country to the Overseas Dominions be carried on without some such provision? It was very necessary to take possession of every vantage point in Canada and guarantee that it should be prevailingly British. The problem should be looked upon as if it were a problem of war strategy. They were told continually that a great lesson was to be drawn from the fact that there had never been a fortress on the boundary line between Canada and the United States. But there was actually a fortress built by the loyalists in 1783, because it was provided that the settlement of the people should be mainly along the boundary line, so it did come about that there was a fortress of flesh and blood. There were some people who stated that it was not possible to have a system of assisted emigration. In view of the fact that every member of the Empire at present was carrying out some system of assisted migration, was it not time to get over that idea? He believed the time had come when a system of emigration, in order to be successful, should be organised as compactly, as thoroughly and as sincerely as a campaign organised in the face of the enemy. He felt that the issue facing the Empire was just as serious to-day as the one it had to face in 1914. Unless they had a system of migration which could be carried on rapidly and successfully, what guarantee was there that Australia might not be lost to the Empire by peaceful penetration? How many of those in that room knew that Washington and Oregon were originally British? They were settled by the Hudson Bay Company just like the rest of Canada. But these areas were penetrated peacefully by Americans and were eventually lost to the British flag. What was going on to-day in Canada? In order to get in behind our tariff walls, the Americans had built innumerable branch factories and they were still pursuing this policy in Canada to-day. Canada might frame its tariffs, but these were ineffective. Take British Columbia, where there existed the finest timber in the world. It belonged largely to the Americans. In that province there were about seven great pulp mills belonging largely to the Americans. British Columbia had the finest mines on the American continent outside Ontario, and these also belonged largely to the Americans. How was this condition of affairs to be met? There was only one way to meet it, and that was to fill Canada full of British subjects as quickly as possible. The points of vantage and of danger must be taken and the country made safe for the Empire. He instanced the condition of affairs in Canada in the time of Louis XIV. when it was proposed that the French settlers should be taken back to France. The French Commander wisely did not take them back to France. He rationed them on the land and settled them as farmers. That was the beginning of seigneurial tenure which laid the foundation of agriculture in the province of Quebec. In 1759 after the conquest of Quebec the Scots Greys and Frasers settled in Nova Scotia and Quebec. In 1783 the British subjects in the United States, rather than haul down the old flag, crossed the boundary into Canada and the British Government gave them land. There were 40,000 of them, and they settled 27 townships in Upper Canada and the eastern townships of Quebec, and laid the foundations of agriculture in Upper Canada. Did not this suggest the key to the solution of the emigration question? In these days, when people had not recovered from the war, the great bulk of the emigrants must be those who had not made good and who had not ready money. If the British Government could spend 50 million sterling a year they could soon place all the available emigration material from this country in the fields of Canada and Australia. It would only be done by organising as though we were in the face of another war. He would send out such emigrants in companies of 200 to, for instance, a valley in British Columbia, under a trained Canadian agriculturist. On the day on which they arrived they would commence making roads and clearing the ground. They would go on clearing their land and building their fences, and in two years—or perhaps in one year—every farm would be in working order, and within two years every farmer might have 40 acres of crop out of 100 acres. The settler would have no anxiety during this time because he would know that the Governments of the Empire were behind him. After a time he would have his farm as a going concern and instead of drifting into the cities he would be permanently attached to the soil. The expense would be practically nothing. It was true that the initial expense would be very great indeed, but every one of these men would be required to pay back in 25 years every cent. of their loan. In the meantime the Governments that made the loan, by working shoulder to shoulder would have the security of these settled and prosperous farms. This would settle the whole question of emigration, but to potter on as we were doing now would end nowhere, it would not solve the question of unemployment, it would not assist England, and it would eventually break up the Empire. He had strong views on this subject, but he believed they were sound. He paid a tribute to the Salvation Army for what it had done in the way of assisting emigration, and congratulated it upon the extraordinarily large proportion of the men and women emigrated under its auspices who had made good. He believed that 96 per cent. of its loans made to assisted emigrants were repaid; in New Zealand the figure was 98 per cent., and the same was true of all the Australian States. By doing something on the lines he had suggested the Governments would be making one of the greatest and best investments ever made in the world.

Mr. T. R. Clougher said that he supposed he was the only person in that assembly who as a boy emigrated to Canada and settled in the backwoods of Ontario, where he spent many years. The thing which did appal prospective settlers from England was the awful loneliness of the Canadian wild, and he thought it well, as Mr. Wade had suggested, that people should go out together and settle as companies. The Government should also increase the paltry 3 millions allowed under the Empire Settlement Act to a more reasonable sum and should see that the money was spent. He drew attention to the peculiar position which Canada occupied, and which did not apply to Australia or New Zealand or any other Dominion—namely, that it was possible for men to go across the American border and find occupation which they could not get in their own country. The Americans were trying to seize the best brains in Canada, and especially had an eye upon the young men graduated from Canadian Universities and Engineering Schools. The British flag meant a great deal to those with British blood because it was associated with freedom and great traditions.

Miss E. St. John Wileman said that a deputation from the Guildhall Conference of Public and Local Authorities had recently approached the Prime Minister (Mr. Baldwin) to ask whether he would place in the general curriculum of education in this country practical instruction in agriculture and kindred out of door occupations. In reply he gave an unqualified assent. Sir Auckland Geddes, before he left for the United States, stated that, in his opinion, the great defect in the whole of the past history of emigration was that there was no testing and proving of emigrants in their native lands before embarking for other countries. In this country we were still muddling on without any practical test at all. More effective measures would have to be taken to inaugurate some efficient system of agricultural training and the testing of would-be emigrants. She and those associated with her had already formulated definite plans for dealing with, testing and preparing migrants for suitable overseas occupations.

Mr. W. L. Griffith, late Secretary, Office of the High Commissioner for Canada, proposed a vote of thanks to the author for his able and painstaking paper. So far as the Dominions were concerned it was evident that if they were to maintain their present prosperity, they must get a larger population. For his own part, he did not think it a very radical proposition to say that a British citizen should be moved free from one part of the Empire where he was an unprofitable unit to another part where he might be productive and profitable, and he agreed with Mr. Wade that the time had come when our traditional policies both in this country and in Canada must be changed. He had recently made a tour in Canada, and as a consequence of what he saw, he believed that the authorities there would have to go a great deal further than they had gone at present in looking after the men who came from Europe. At Montreal he questioned some of those who were being deported and his impression was that if they had been a little more carefully treated, although the officials did all that could be expected, if there had been more organisation to deal with the men they could have been turned into decent Canadian citizens. In Canada, until the cost of living became at least as cheap as in the United States, and the poor man in Canada wrote to the poor man in Europe saying "Come," the volume of immigration, notwithstanding the various efforts, would not be what it ought to be. During the time he had spent in the High Commissioner's Office he had seen a stream of decent citizens of middle age who had somehow failed to make good in England. He could no help feeling that the reason why they had failed to made good was because their mothers had insisted that they should wear white collars and black coats. In the changing condition of things at present he would say to the parents that instead of looking for professional and commercial openings, they should turn the minds of their sons into more useful and profitable channels. He would have no pity for any able-bodied young man who went to Canada and came back and said that he could not make a living. In the healthy atmosphere of that country he should be able to develop a physical and moral integrity which probably in the older country he would not have an opportunity of doing.

Lord Askwith, K.C.B., K.C., D.C.L., Chairman of Council, seconded the motion. The subject he said was so vast that it would be an advantage if another discussion could be held at a later date. Mr. Noxon had only been able to treat the bare fringe of the subject, but his intention was to show in a broad way what the position was.

He had briefly made an allusion to the question of free passages. Something could well be done on that line, because it was of no use asking a man who had only a few shillings to provide the pounds necessary for his passage. He believed that under a properly organised system a very large percentage of the money lent would be repaid and that the Governments would not lose by such a concession. Another question to which Mr. Noxon had only briefly alluded was that of group emigration; this matter of group and of family emigration was very important. Lord Askwith added that he wished to include in the vote of thanks not only the reader of the paper but also the Chairman, Lord Airlie, amongst whose countrymen had been some of the finest Empire-builders that Britain ever had.

The motion was carried unanimously.

Mr. Noxon, in replying on behalf of Lord Airlie and himself, mentioned that in his house he had a parchment showing him to be a descendant of the New England loyalists. He was glad that the discussion had been so full; but it would take a whole day to exhaust any one division of the subject.

The meeting then ended.

LA VIE INDUSTRIELLE EN FRANCE.

Le Laboratoire "Ampère" pour les Essais a 1 Million de Volts.

Le 11 décembre a été inauguré à Ivry (banlieue de Paris) le laboratoire installé par la Compagnie Générale d'Electro-Céramique, pour des essais à très haute tension. Ce laboratoire auquel on a donné le nom du grand physicien Ampère, est équipé pour produire couramment des tensions supérieures à 1,000,000 de volts. L'inauguration, par le sous-Secrétaire d'Etat de l'Enseignement technique et le professeur D'Arsonval, président de la Compagnie, a été accompagnée d'une série d'expériences intéressantes. C'est la première fois que la tension de 1 million de volts a été produite en Europe.

Le bâtiment édifié spécialement pour le laboratoire, a 36 mètres de longueur, 20 mètres de largeur et 18 mètres de hauteur. Il est donc suffisamment vaste pour que l'influence des parois soit négligeable.

Le courant est produit par un alternateur étudié spécialement et muni d'amortisseurs, grâce auxquels la courbe de tension ne diffère pas de la sinuosité théorique de plus de 2%, quel que soit le débit.

Les six extrémités des enroulements du stator sont sorties, ce qui permet, soit de n'employer qu'une phase, soit, si l'installation fonctionne en triphasé, de faire des connexions en étoile ou en triangle. L'alternateur est entraîné par un moteur asynchrone synchronisé, qui démarre en asynchrone sous tension réduite, le rotor étant court-circuité lui-même; lorsque la vitesse de régime est atteinte, on y envoie du courant continu, et le moteur est "accroché." De cette façon, on a un courant de fréquence constante à l'alternateur. La puissance est de près de 200 chevaux.

Le laboratoire contient 3 auto-transformateurs monophasés 500/375.000 volts, munis d'enroulements de compensation réduisant la dispersion dans une forte proportion.

En excitant les trois transformateurs au moyen des 3 phases de l'alternateur, on obtient aux sorties secondaires du courant triphasé à 650.000 volts entre phases.

En branchant, au contraire, le primaire du premier transformateur sur une phase de l'alternateur dont le neutre est à la terre, et en excitant respectivement les 2ème et 3ème transformateurs au moyen de quelques spires de l'enroulement des 1er et 2ème, on peut obtenir entre la sortie du secondaire du 3ème transformateur et la terre des tensions supérieures à 1 million de volts efficaces, soit plus de 1.400.000 volts de crête.

Les principales expériences effectuées le jour de l'inauguration ont été les suivantes:

La réalisation d'un champ tournant à 300.000 volts; la production d'étincelles à 500 000 volts et à 1 million de volts entre des sphères de 1 mètre de diamètre ou entre des pointes; la charge statique d'une personne isolée du sol sous l'action d'un champ à haute tension; enfin l'essai de contournement par l'arc d'une chaîne d'isolateurs à 1 million de volts.

C'est principalement pour les essais d'isolateurs que ce laboratoire a été établi; il doit concourir à la production du matériel d'électrification à haute tension prévu en France. Il servira également à des recherches scientifiques et industrielles générales sur les très hautes tensions.

Exposition de Physique et de Telegraphie Sans Fil.

(Paris, 30 Novembre-24 Décembre.)

La Société française de Physique, à l'occasion de son cinquantenaire, a pris l'initiative d'organiser, au Grand Palais des Champs-Elysées, une importante exposition de Physique et de T.S.F., qui constitue une innovation dont le succès s'est affirmé très grand, à tel point qu'on a dû prolonger d'une semaine sa durée.

Dans le cadre, vaste et élégamment décoré, de la nef vitrée du Palais, le visiteur rencontrait d'abord quelques appareils anciens, fort curieux, tels qu'une machine pneumatique de Nollet, du 18e siècle, une lentille à échelons de Fresnel, des spécimens de transmissions de dessins et photographies par le système Caselli, vers 1860, et par le système Belin, en 1907. Ce dernier système a été fortement perfectionné depuis lors.

A quelques pas de ces instruments anciens, les appareils les plus modernes s'offraient à la curiosité du visiteur: un poste de sectionnement électrique en plein air à 150,000 volts, avec disjoncteurs tripolaires, par exemple. Nous ne pouvons que citer ici quelques stands, et d'abord l'exposition rétrospective de la Société du Gaz de Paris, montrant tous les genres de becs employés depuis 1830 jusqu'à aujourd'hui pour éclairer les rues de la capitale; puis, la "salle d'optique," série de stands où l'on exécutait des expériences et démonstrations nécessitant l'obscurité.

Parmi les expositions des collectivités, mentionnons celle du Conservatiore des Arts de Métiers, offrant en particulier une copie du mètre prototype; celle du Radio-Club; celle de l'Office national des Inventions; celle de la Société Française de Physique.

N'oublions pas, enfin, de signaler quelques expositions des grands constructeurs français, tels que la Cie Thomsom-Houston, le Matériel téléphonique, la Société Alsacienne de Constructions Mécaniques, la Soudure autogène, le Comité électrométallurgique de France, les Aciéries d'Imphy (Nièvre), la Cie de Fives-Lille, la Cie générale d'Electricité, la Cie Générale d'Electro-Céramique, les Ateliers de Constructions électriques de Delle, etc., qui avaient mis en vue leurs plus intéressantes fabrications.

L'électricité, et particulièrement ses emplois pour l'éclairage et pour la radiographie, tenaient naturellement la place principale dans l'Exposition; en particulier, les constructeurs de postes de radio pour amateurs de broadcasting avaient apporté, en grand nombre, leurs dispositifs les plus récents, permettant d'entendre les émissions françaises et anglaises.

UN NOUVEAU PROCÉDÉ DE DÉCINTREMENT DES PONTS EN BÉTON ARMÉ.

Les ponts en maçonnerie ou en béton armé sont généralement construits sur une charpente en bois reposant à sa base sur des "boîtes à sable." Pour décintrer le pont, on ouvre dans chaque boîte un orifice qui permet l'écoulement du sable, et par suite, la descente de tout le cintre.

Cette méthode classique laisse la voûte prendre sa flèche naturellement, sans possibilité de la corriger. Un nouveau procédé de décintrement très hardi vient d'être imaginé par M. FREYSSINET, qui l'a employé à plusieurs grands ouvrages en béton armé. Dans le procédé FREYSSINET, l'arc en béton armé n'est pas claveté avant le décintrement: on laisse au sommet un espace vide jusqu'à la fin de la construction. Pour décintrer, on dispose dans cet espace, horizontalement, des vérins hydrauliques très puisants. On les met en action, et les deux moitiés de l'arc se soulèvent, grâce à leur élasticité, déchargeant le cintre et l'échafaudage. On remplit alors de béton riche l'intervalle des arcs, de part et d'autre des vérins, et l'on peut retirer ceux-ci.

Le grand avantage de ce système est que le constructeur est maître, jusqu'au dernier moment, de la flèche du pont. Il peut, en agissant sur les vérins, modifier la forme de la voûte pour faire coïncider exactement la fibre moyenne avec la courbe théorique prévue par le calcul. Il peut donc corriger au besoin un affaissement excessif des arcs. De plus, on connaît exactement l'effort à la clé de l'ouvrage, puisque c'est la force exercée par les vérins pour maintenir les arcs ouverts Enfin, s'il se produit une fissure ou un accident quelconque à la maçonnerie pendant l'opération du décintrement, on peut ramener la construction sur son cintre presque instantanément, puisqu'elle ne s'est soulevée que de quelques centimètres, et que le cintre n'a pas bougé.

Ce procédé a été appliqué avec succès, d'abord au pont de Villeneuve-sur-Lot, puis à celui de St. Pierre-du-Vauvray, sur la Seine, près de Rouen, dont l'ouverture de 134 mètres est la plus grande portée atteinte jusqu'ici par un arc en béton armé.

NOTES ON BOOKS.

THE NEW INDUSTRIAL ERA. By Sir Charles W. Macara, Bt. Manchester: Sherratt and Hughes.

The contents of this volume consist for the most part of articles contributed by the author to the press in 1922 and 1923. While the title is general the chapters deal almost entirely with various problems and aspects of the cotton trade. There can be very few people who have had a longer or more intimate connexion with cotton than Sir Charles Macara, and in his services to the industry—notable amongst them his triumph in the matter of the Brooklands Agreement—he has been second to none. Whatever he has to say of this trade, therefore, is of the greatest authority and weight.

It is extremely refreshing to note that, in spite of the present depression, Sir Charles has a fine faith in the ultimate prosperity of our cotton trade. We hear much of rivalry from other countries. What does Sir Charles say about America, for instance? "While we have the inherited skill of generations to produce our cotton goods, the Americans have to carry on the cotton industry as best they can with an alien population. If you go into an American cotton mill you will find workpeople of five or six different nationalities engaged, and the personnel is always changing. The employers never know whom they will get next—Italians or Spaniards or Poles or what not; and the running of a mill under such conditions is like a Tower of Babel.

"Very few of our cotton operatives go from here to work in America, and when they go they soon want to come back. They know how inferior the conditions are in American cotton mill towns."

As to the cry of "cheap yellow labour" Sir Charles is no less optimistic. He learnt from a Japanese gentleman, sent over by the Japanese Government, that nearly all the operatives in Japanese cotton mills come fresh from the fields, and require all kinds of inducements to get them to remain at factory work. According to him, there is little in the cry of Japanese competition. "To begin with, the Japanese are dependent on English machinery, which costs them double what it costs the English manufacturer to erect. Then the employers have to build houses for their workers, provide them with amusements, and educate their children. They are by no means in a strong position, and the weakest thing of all about their position is

that as soon as their workpeople have saved a little money they are off again to the country, and the employers have to start with a fresh set of workers whom they have to train."

The whole book is full of ripe wisdom and information, and will appeal not only to students of the cotton trade but to all interested in economics and the relations between employers and employed.

Plan Copying in Black Lines for Hot Countries. By B. J. Hall, M.I.Mech.E., London: Sir Isaac Pitman & Sons, Ltd. 2*s*. 6*d*. net.

Engineers and architects working in hot climates are familiar with the difficulty of securing good black line copies of their drawings. The process described in this booklet is based on one which was largely used by photographic printers in this country before the introduction of "Ordoverax," although modifications have been made to suit special conditions. The author states that no great technical skill is involved in using the process: with a little practice the native operators having some experience in blue printing will be able to produce satisfactory copies. The process, which is fairly simple, is very clearly described, and seems likely to prove of great service to those for whom it is intended.

GROWTH OF CHINESE LACE INDUSTRY

China's lace trade, although still essentially a home industry, is becoming an important factor in the nation's commerce. Exports of Chinese lace have mounted from the negligible figure of 140,682 haikwan taels in 1914 to 5,230,284 haikwan taels in 1921, which latter value represents an increase of 95 per cent. over the 1920 exports of 2,678,530 taels. The United States' share of this trade was 4,195,494 taels in 1921. Australia ranks second, Great Britain third, and Canada fourth as buyers of Chinese lace.

Chefoo formerly led in exports of lace from China, but in 1919 Shanghai rose to first place with about three-quarters of the total shipments to its credit. Chefoo still holds second place, and small amounts are being shipped from Ningpo, Swatow and Nanking.

According to a report by the United States Assistant Trade Commissioner at Shanghai. silk torchon and Cluny laces were originally introduced into Chefoo (Shantung Province) by missionaries, who took this means of teaching the native women and girls a profitable home employment. In 1895 the industry was placed on a commercial basis by the establishment of the Chefoo Industrial Mission for the sale of these products. Chefoo's entrance into competition with European laces came during 1910, when thread laces were manufactured by using Belgian and French patterns. Up to this time Australia had taken the bulk of the torchon laces, while the silk Clunys found their way to America.

Sales of lace to the United States did not assume commercial importance, however, until the introduction of filet-lace making into China. During 1916 two American firms began buying filet laces, which at that time could only be obtained in small amounts by combing the interior towns and cities. Although the industry was started in Chefoo, the real centres to-day are Pootung (Shanghai's industrial district) and the Wusih (about 70 miles north of Shanghai). The better grades of filet lace are made in the Wusih district, where the workers have had the advantage of the industrial school training. The narrow widths (six and nine holes) are produced here. Pootung claims to have about 230 establishments, employing approximately 25,000 women workers. In this district, which manufactures the bulk of the wider filet (from 30 to 50 holes), the patterns are worked in by needle in what is known as running stitch, and are somewhat inferior to the Wusih product. The combined output of Pootung and Wusih is estimated at over £300,000 annually. Most of the filet laces are produced by women and children, although there are some men workers, chiefly on the larger pieces, such as table covers and bedspreads.

During 1920 the Irish lace industry was introduced into Swatow and adjoining districts, and it is claimed that they are turning out a higher class article than is produced in Ireland. One American firm has 18,000 workers employed in this district with an annual output of over £250,000. A small amount of Venetian or mosaic laces is made in the Shanghai district.

The net or mesh which is used as the basis of filet lace is made entirely by hand, principally in the Ningpo district of Chekiang Province. It is collected by agents who bring it to the lace centres of Pootung and Wusih.

British thread has always held a dominant position in the industry, although during the war Japanese thread entered into competition with it. The Japanese thread is said to be defective in wearing qualities, the strands separating when the laces are washed, thereby rendering them loose and uneven. Recently a Chinese-made thread has entered the market which is a trifle better in quality than the Japanese. So far a very small amount has been available, but it is making itself felt in the trade. American threads have been imported in negligible quantities. A limited amount of French and Belgium thread is imported for the finest grades of laces.

The thread is furnished to the workers by native brokers, dealers, or buyers, who pay their wage upon delivery of the finished products. The Shanghai scale of wages ranges from eight to fifteen cents per day, the average wage being 10 cents silver.

Filet and other laces are usually bought up by scouts or native brokers touring the various lace districts. They are then brought into the markets, such as Shanghai, and sold to exporting concerns in whose warehouses they are inspected for the following defects: (1) Torn borders, (2) rust, (3) broken holes, (4) soiled condition. Laces are usually graded into three classes, rejects being disposed of in job lots to Chinese peddlers.

Great difficulty is experienced in getting the Chinese lace workers to realise the importance of cleanliness. Often as high as one-third of a shipment must be classed as seconds owing to soiled condition. Rigid foreign supervision alone reduces this fault to a minimum, but where the laces are collected from Chinese homes it has been found impossible to inculcate the desirability of cleanliness.

After inspection the laces are measured, carded and labelled preparatory to shipment, bolts running from 12 to 100 yards each. The lace is then packed in cardboard boxes holding 50 pounds of lace, usually 50 bolts. These boxes are then wrapped in oiled paper, covered with muslin, sewed, and stencilled for shipment, which is usually by parcel post.

AMERICAN versus EUROPEAN SUMAC.

The Research Division of the United States Bureau of Foreign and Domestic Commerce has prepared a memorandum on the importance of sumac to the American tanner from which the following is taken:—

The sumac of commerce consists of the dried leaves, leaf stems, and stalks from various plants of the Rhus family, which are found abundantly in almost all regions of the temperate zones. These varieties however, do not all possess the the same value as tanning agents. The principal European species and most valued for their tannin content, are the Silician sumac (*Rhus corairia*) and that from central Italy (*Rhus continus*), which varieties are also found in Yugoslavia; the sumac of France, Spain, and Greece belongs in the same category. American sumac is obtained from various species of Rhus, the best thing being that known as white sumac derived from *Rhus glabra;* dwarf sumac, from *Rhus copallina;* and staghorn sumac, from *Rhus hirta.* There are several other varieties, but their yield of tannic acid is insufficent to render them commercially valuable.

Sumac is found abundantly in the United States and is especially accessible east of the Mississippi River, from Maine to Georgia. Sumac is harvested on a large scale in Virginia, North Carolina, Maryland, and Pennsylvania. The American plant, owing to careless gathering and curing, gives a darker coloured leather than the sumac imported from Sicily, and, since sumac is mainly used for tanning light-coloured leather, this characteristic renders the American product less desirable than the Silician and therefore decreases its value.

Buyers of sumac leaves for grinding depend largely upon colour for determination of value. A bright green colour is evidence that the leaves have suffered neither from rain after being gathered nor from heating during the process of drying. Sumac should be kept in the drying house for at least one month before being sent to market. The leaves of the upper extremities of the stalks are always richer in tannic acid than those of the base; and the increase in the age of the plant is accompanied by a general diminution in this acid. To insure a maximum value for tanning purposes the leaves should be gathered when full of sap, before they have begun to wither or have been affected by frost. For the purpose of tanning white and light coloured leathers, collection should be made in June; but when darker colours are desired, collection should be made in July. The percentage of tanning in American sumac gathered in June is 23, while that gathered in July is 27. It is evident therefore that if a maximum of tannic acid is desired the sumac should be collected in July; but if delicacy of tint is the main object, then collections should be made in June. The colouring matter in the leaves has an important influence in determining the value of the product. The portions of the plant usually considered of value for tanning purposes are the leaves and the stems; but as the stalks contain from 5 to 10 per cent. tannin—an amount too large to discard, considering expense incurred in collecting and hauling to market—an extract could be made from them and the off-coloured leaves that would be a satisfactory tannage where colour is not of premium importance.

The tannin content of good sumac ranges from 25 to 28 per cent.; although some samples have, on analysis, been found to contain from 32 to 35 per cent. of a tannin-allied to gallotannic, with some ellagitannic acid, and a colouring matter which gives yellows with alumina and tin mordants. Similar analyses have proved that the tannin content of dwarf sumac ranges from 19 to 35 per cent. that of the staghorn, from 21 to 30 per cent.; and that of white sumac from 21 to 28 per cent.

For white or light-coloured leathers, sumac is the best tannage known; hence its general use in the tanning of moroccos, roans, skivers, glove leathers, etc. It is also used for brightening leathers of darker tannages, such as mimosa and gambia, the colouring matters of which warm sumac liquors readily dissolve. Sumac-tanned leathers are less liable to decay than those of other tannages and are largely used for book-binding, and other purposes in which durability is a primary requisite.

Extracts occur as liquids of 42° and 51°, containing about 22 and 26 per cent. of tannin respectively. The domestic production in the United States of sumac extract from both native and foreign leaf in 1914 amounted to 4,512,361 pounds, valued at $129,631; and in 1919 (the latest year for which statistics are available), to 4,507,433 pounds, valued at $253,088. The domestic consumption, however of the prepared extract in 1919 aggregated 6,669,642 pounds together with 4,656,000 pounds of raw sumac representing a total of 11,325,642 pounds, valued at a $590,381. One pound of sumac extract contains approximately the same amount of tannin as one pound of sumac leaf.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

JANUARY 23.—**G. ALBERT SMITH**, "Cinematography in Natural Colours—further Developments" (with illustrations—scenes from H.R.H. The Prince of Wales's Tour in India). **GEORGE E. BROWN**, F.I.C., Editor of the *British Journal of Photography*, will preside.

JANUARY 30.—**SIR RICHARD ARTHUR SURTEES PAGET**, Bt., "The History, Development and Commercial Uses of Fused Silica." **SIR HERBERT JACKSON**, K.B.E., F.R.S., will preside.

FEBRUARY 6.—**IYEMASA TOKUGAWA**, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." **LORD ASKWITH**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

FEBRUARY 13.—**H. MAXWELL-LEFROY**, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle." **SIR ASTON WEBB**, K.C.V.O., C.B., P.R.A., will preside.

FEBRUARY 20.—**PERCIVAL JAMES BURGESS**, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

FEBRUARY 27.—**CHARLES S. MYERS**, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

MARCH 5.—**MAJOR-GENERAL SIR FABIAN WARE**, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries."

MARCH 12.—**ALAN A. CAMPBELL SWINTON**, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.)

MARCH 19.—**R. L. ROBINSON**, Member of the Forestry Commission, "The Forests and Timber Supply of North America." **LORD LOVAT**, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., will preside.

MARCH 26.—**NEAL GREEN**, "The Fishing Industry and its By-Products."

Dates to be hereafter announced :—

SIR LYNDEN MACASSEY, K.B.E., "London Traffic."

BRIGADIER-GENERAL SIR HENRY MAYBURY, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "Roads."

FRANK HOPE-JONES, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum."

J. ROBINSON, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MRS. ARTHUR MCGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." **LORD ASKWITH**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons at 4.30 o'clock :—

FEBRUARY 15.—**SIR RICHARD M. DANE**, K.C.I.E., Commissioner, North India Salt Revenue, 1898-1907; Foreign Chief Inspector, Salt Revenue, China, 1913-18, "Salt Manufacture in India and China."

MAY 2.—**JOCELYN F. THORPE**, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced :—

BHUPENDRA NATH BASU, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons at 4.30 o'clock :—

FEBRUARY 5.—**F. W. WALKER**, "The Commercial Future of the Backward Races, with Special Reference to Papua." **SIR GEORGE R. LE HUNTE**, G.C.M.G., will preside.

MARCH 4.—**THE HON. T. G. COCHRANE**, D.S.O., "Empire Oil: The Progress of Sarawak." **THE RT. HON. LORD BEARSTED** will preside.

MAY 27.—**C. GILBERT CULLIS**, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

CANTOR LECTURES.

ERIC KEIGHTLEY RIDEAL, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." Three Lectures.

SYLLABUS.

LECTURE I: JANUARY 21.—Nature of Colloids. Properties of interfaces. Surface tension and adsorption. Decolourisation, gas absorption, stream line filter. The work of Hardy and Langmuir. Orientated adsorption, Catalysis, Enzymes, Specific germicides, lubricants.

LECTURE II: JANUARY 28.—Suspension Colloids. Peptisation, protection and precipitation. Colloidal Mill. Electric cataphoresis and endosmose. Peat drying. Colloidal metals, Colloidal fuel, Ore flotation Smokes, condensation of fumes, powdered fuels. Mists, Insecticides.

LECTURE III: FEBRUARY 4.—Emulsion Colloids. Preparation and Stabilisation. Coal tar disinfectants, Milks, Phase inversion-biological importance, greases, antigens. Soaps. Ionic micellae.

Adsorbing Gels. Silica gels, ferric oxide and alumina, clays, vaseline, rubber and textiles. Membranes, permeability. Equilibria at membranes, application to leather.

EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

COBB LECTURES.

Monday evenings, at 8 o'clock:—

DR. T. SLATER PRICE, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, JANUARY 21..British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Prof. P. Nobbs, "Architecture in Canada."

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Mr. E. J. Sewell, "The Historical Value of the Book of Jonah" (being the Gunning Prize Essay for 1923).

Geographical Society, Lowther Lodge, Kensington Gore, S.W., 5 p.m. Captain P. K. Boulnois, "Field Longitudes by Wireless."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal Meeting). Mr. E. H. Shaughnessy, "Broadcasting."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 7 p.m. (Graduates' Section.) Mr. E. L. Diamond, "Recent Improvements in Locomotive Efficiency."

University of London, King's College, Strand, W.C., 6 p m. M. E. Augier, "Le Théatre Francais en 1850" (in French.)

5.30 p.m. Dr. O. Voladlo, "Channels of Modern Czech Literature." (Lecture I.)

TUESDAY, JANUARY 22..Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Mr J S. Dow, "Co-ordination of Research in Illuminating Engineering and Some Practical Applications."

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

Photographic Society, 35, Russell Square, W.C., 7 p.m. (Meeting of the Kinematograph Group). Messrs. D. Bloch, L. Everleigh and others on "Cinematograph Negative Film: What We Want and What We Get."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. W. E. Dixon, "Drug Addictions." (Lecture II.)

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Commander W. F. Boothby, "Empire Air Service to India and Australia."

University of London, King's College, Strand, W.C., 5.30 p.m. Rev. P. Dearmer, "Seventeenth Century Art—Part II. Northern Europe." (Lecture I.)

5.30 p.m. Sir Bernard Pares, "Russia before Peter the Great to 1861." (Lecture I.)

5.30 p.m. Mr. J. R. Beard, "Electric Power Mains." (Lecture I.)

WEDNESDAY, JANUARY 23..Microscopical Society, 20, Hanover Square, W., 7 p.m. (1) Captain J. W. Bamfylde, "Some Failures in Steel as revealed by the Miscroscope and recorded by Photography." (2) Mr. H. B. Milner, "The Use of the Miscroscope in the Petroleum Industry."

University of London, University College, Gower Street, W.C., 3 p.m. Prof. E. G. Gardner, "Problems of the Inferno" (Lecture I.)

At King's College, Strand, W.C., 5.30 p.m. Mr. C. R. Peers, "The Place of Art in the Study of Mediæval History."

At Kingsway Hall, Kingsway, W.C., 6.30 p.m., Mr. L. V. Wilkinson, "Representative Living English Writers." (Lecture I.)

Constructive Birth Control, Society for, Essex Hall, Strand, 8 p.m. Rev. D. Cameron, "The Race Problem in Scotland."

THURSDAY, JANUARY 24..Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Dr. J. E. Ramsbottom, "Dopes and Fabrics."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Linnean Society, Burlington House, Piccadilly, W., 5 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Auctioneers, and Estate Agents, Institute, 34, Russell Square, W.C., 7.30 p.m. (Junior Section.) Mr. H. Knapton, "Second-hand Books in Relation to the Auctioneer in General Practice."

Economics and Political Science, London School of, Houghton Street, Aldwych, W.C., 5 p.m. Sir Hubert L. Smith, "The Economic Laws of Art Production." (Lecture II.)

Royal Institution, Albemarle Street, W., 5.15 p.m. Mr. W. Sickert, "Straws from Cumberland Market." (Lecture II.)

Mechanical Engineers, Institution of, (Midland Section), The University, Edmund Street, Birmingham, 7.30 p.m. Mr. C. Jones, "Mechanical and Electrical Equipment as Applied to Coal Mining."

University of London, University College, Gower Street, W.C., 5.15 p.m. Prof. J. E. G. de Montmorency, "Comparative Customary Law of Europe and Asia." (Lecture I.).

8 p.m. Prof. H. E. Butler, "Roman Private Life." (Lecture I.)

At (R.F.H.) School of Medicine for Women, Hunter Street, W.C., 5 p.m. Prof. W. C. Cullis, "Respiratory Exchanges." (Lecture I.)

FRIDAY, JANUARY 25. Royal Institution, Albemarle Street, W., 9 p.m. Sir Aston Webb, "The Future Development of London"

Mechanical Engineers, Institution of, Storey's Gate, S.W., 6 p.m. Major G. Le Q Martel, "The Progress of Mechanical Engineering in the Military Service."

Aeronautical Engineers, Institution of, at the Engineers Club, Coventry Street, W., 6.30 p.m. Lt.-Col. V. C. Richmond, "Some Problems in Connection with the Structure of Rigid Air Ships."

Physical Society, Imperial College of Science and Technology, South Kensington, S.W., 5 p.m.

Engineers, Junior Institute of, 39, Victoria Street, S.W., 7.30 p.m. Prof. E Edser, "Molecular Attraction and its Relation to Engineering."

Shakespeare Association, King's College, Strand, W.C., 5.30 p.m. Dr. W. Starkie "Shakespeare and the Spanish Drama."

SATURDAY, JANUARY 26..Royal Institution, Albemarle Street, W., 3 p.m. Mr. W. Wallace, "The Couperin Dynasty."

Journal of the Royal Society of Arts.

No. 3.714 VOL. LXXII.

FRIDAY, JANUARY 25, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 28th, at 8 p.m. (Cantor Lecture). ERIC KEIGHTLEY RIDEAL, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." (Lecture II.)

WEDNESDAY, JANUARY 30th, at 8 p.m. (Ordinary Meeting.) SIR RICHARD ARTHUR SURTEES PAGET, Bt., "The History, Development and Commercial Uses of Fused Silica." SIR HERBERT JACKSON, K.B.E., F.R.S., will preside.

INDIAN SECTION.

FRIDAY, JANUARY 18th, 1924; SIR THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, in the Chair.

A paper on "The Survey of India" was read by COLONEL H. L. CROSTHWAIT, C.I.E., R.E., retd., late Superintendent, Survey of India.

The paper and discussion will be published in a subsequent number of the *Journal.*

CANTOR LECTURE.

On MONDAY, JANUARY 21st, 1924, DR. ERIC K. RIDEAL, M.B.E., B.A., D.Sc., F.I.C., of the Chemical Laboratory, The University, Cambridge, delivered the first lecture of his course on "Colloid Chemistry."

The lectures will be published in the *Journal* during the summer recess.

REPRINT OF CANTOR LECTURES.

The Cantor Lectures on "Precise Length Measurements," by Mr. J. E. Sears, Jun., C.B.E., M.A., M.I.Mech.E., A.M.Inst.C.E., have been reprinted from the *Journal,* and the pamphlet (price 4*s.*) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2.

A full list of the lectures, which have been reprinted and are still on sale, can also be obtained on application.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained by Fellows on application to the Secretary.

MANN JUVENILE LECTURE.

The third and concluding Juvenile Lecture of the present session was delivered on Wednesday afternoon, January 16th, by MRS. JULIA W. HENSHAW, F.R.G.S., Croix de Guerre, the subject being "Among the Selkirk Mountains of Canada (with Ice-axe and Camera)." The RIGHT HON. LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, presided.

The lecture was fully illustrated by a magnificent collection of hand-painted lantern slides, which faithfully depicted the gorgeous masses of colour and the awe-inspiring grandeur of the scenery in that part of the Dominion—British Columbia—where both the Selkirk and Rocky Mountains reach their maximum of elevation. Mrs. Henshaw gave an account of the journey she and her companions made in 1896, when history making in the Rocky mountains was in its infancy, and very few men had followed the early footsteps of such intrepid wayfarers as David Thomson, whose record in Canada was unequalled, dominating as it did the history of the Columbia-Kootenay Valley; Sir George Simpson, Captain John Palliser, David Douglas, and Simon Fraser—those grand old pioneers who first blazed the trails and navigated the waterways of British Columbia.

The scenes shown on the screen included magnificent views in colour and monotone of the Bow River, Castle Mountain, Vermilion and Sinclair Passes, Mount Whymper, Mount Ball and other glacier-covered mountain ranges; Lower Columbia Lake, the Oregon (now called the Columbia) River, the longest and largest waterway in Western Canada, whose source in the mountains was first discovered by David Thomson in 1808; the Crown Circular Road, a great loop of some 500 miles—a marvellous piece of mountain engineering, where man had conquered nature; as well as the glorious Alpine region, with its virgin peaks, unknown, un-named, and unclimbed. She also referred to the ochre beds and to the fact that long before the advent of the white man the Kootenay Indians had used these colourings to decorate their teepees with weird designs and to adorn their bodies for battle or religious ceremonial. Views of the natural monuments regarded by the Indians as the dwelling place of the Great Spirit, and of the holy ground visited by the young Kootenay Indians on attaining manhood in order to keep vigil, as the Christian Knights did of old, were also shown and explained.

In some places, Mrs. Henshaw said, the valleys were literally blue with flowers, so blue that one felt as if a piece of Heaven had dropped down upon the earth. Among the numerous slides thrown upon the screen were coloured photographs of Indian pipe, that degenerate member of the beautiful family of heaths; the timid winter green, called by Asa Gray "A single delight;" snow lilies, with blooms as white as snow itself, which push their way through the snow in early spring; magenta calypsos; purple dragon heads; scarlet columbines; rose-red bergamot; spangled blue flax; harebells; vetches of every hue; hawkweeds; ragworts; arnicas; golden rod; wild roses; honeysuckle; gaillardias; waxen-belled rhododendrons; pale green feathery Lyall's larches; flaming cottonwoods; a species of cyclamen; anemones; all the genus of blueberry, bilberry and cranberry; red osier dogwood, arrow wood, capberry and other fiery fruited shrubs. Pictures of birds and animals plentiful in that region were shown and described, including brown, black, and grizzly bears; marmots; moose; elk; wapiti; mountain sheep; and mountain goats which closely resemble the species in the Himalayas. She remarked how strange it was that two so widely different animals as the moose and the prairie chicken should be fond of dancing, and said it was not at all an uncommon sight to see a prairie chicken perform a first-class shimmy dance. The Indian children in their own native dances had cleverly imitated the bird.

When their journey along the Happy Valley and through the north-western prairie lands had ended, Mrs. Henshaw said they had visions of the great agricultural possibilities of the country, and pictured how it would look in the years to come. Much of the vision had been realised to-day; but

"Thank God, there is always a land of
Beyond
For those who are true to the trail,
A vision to seek, a beckoning peak,
A farness that never will fail."

The Chairman moved a hearty vote of thanks to Mrs. Henshaw for her admirable lecture and for the beautiful pictures which she had shown. The scenery was the grandest in the whole world, and he knew of no finer sight than the scene seen at the break of dawn over the Rocky Mountains. It was a sight which remained in one's mind for a great many years, and he hoped some of the younger members of the audience would in course of time be able to see for themselves the glories and wonders of Canada, one of the most splendid jewels in the British Crown.

Mrs. Henshaw acknowledged the vote of thanks and the meeting then concluded.

PROCEEDINGS OF THE SOCIETY.

◆

CANTOR LECTURES.

COCOA CULTIVATION IN THE BRITISH TROPICAL COLONIES.

By SAMUEL HENRY DAVIES, M.Sc., F.I.C.

LECTURE I.—*Delivered November 12th,* 1923.

The cocoa tree is a native of the tropical forest and is probably derived from the upper basin of the Orinoco and Amazon. This cannot be stated with any certainty because the Indians had cultivated the tree for centuries before the Spanish Conquest and the seed had been widely scattered by birds or monkeys in the neighbouring forests. The first Spanish settlers carried the seed from Central America and the Spanish Main to Jamaica, Trinidad and the lesser Antilles. Notably in Jamaica a large number of "cocoa walks" were found by the first British Colonists at the time of the Commonwealth and it is on record that a choice variety of bean was planted by the Spaniards in Trinidad in Elizabethan times. A disaster overtook all the Island plantations in 1727, described as a "blast," variously interpreted to mean either a hurricane or a destructive blight. Thirty years later a hardier variety from the Venezuelan coast was cultivated in Trinidad.

The fact of its forest origin is important, if we would understand the climatic conditions and the several precautions required in establishing a cocoa cultivation. Thus, the tree is sensitive to cold and drought, it cannot flourish where the temperature drops below 65° Fahr., and grows best in a humid atmosphere, with a mean temperature of 75° to 78° Fahr. This serves to define the range of latitude within which it can be profitably cultivated — some 20° North to 20° south of the Equator. Cocoa can be grown to advantage from sea level to 1,000 feet and in equatorial regions may give good crops up to 2,000 feet, in contrast with coffee and tea which flourish at much greater altitudes. The rainfall should be well distributed, the exact requirements naturally depending on the water level and nature of the soil, and the humidity of the air. A rainfall of from 60 to 120 inches is advantageous, with extreme limits of 45 to 200 inches.

THE TREE.

The only species of commercial importance is the Theobroma Cacao of Linnaeus. It grows quickly, and under favourable conditions, reaches its full height of 20 to 25 feet in a dozen years. But in deep alluvial soil, on Trinidad estates, we may find trees planted in slavery times 40 feet and more in height. The extreme case is to be found on the Amazon, where the native does not willingly interfere with the ways of Providence, and there I have seen it shooting up in the forest to amazing heights.

The tree branches about 4 feet from the ground—from 3 to 5 branches is the rule. If allowed to grow freely it would form a dense network of branches; suckers would spring up and form a secondary system of branches. In the early stages the large oval leaves are a beautiful olive brown shading to pink, soft and transparent and hanging downwards, but they gradually thicken, changing to light green and finally to leaves of a full green tint and leathery texture. A curious feature of the cocoa leaf is the double articulation at either end of the leaf stalk, which forms a universal joint and makes it possible for the leaf to rotate in any direction, so that the upper surface always faces the light.

The flower buds appear on the trunk and main branches, often forming in the axiles of leaves but not developing until the leaves have dropped off at that point. The full beauty of the cocoa tree is displayed after the rains. Then may be seen in their framework of leaves (brown shading to green) clusters of tiny cream or pink blossoms studding the rough trunk, with more blossom scattered along the branches—tens of thousands of flowers of which only 2 or 3 in a thousand will fructify. Alongside the blossom we may find tiny cucumber-like pods, together with pods at every stage up to the full grown fruit. One tree may carry green pods ripening to lemon yellow, while a neighbouring tree may bear splashed crimson pods ripening to an orange vermilion. While there are usually two main crops dependant on the rainy season, a scattering of flowers or pods can be found for ten or eleven months in the year. The tree is never wholly bare of leaves. It may bear blossom at the third year, but it should not be allowed to bear fruit until the fourth or fifth year. It should be in full bearing at the tenth year or earlier, if conditions are favourable.

How the flower is fertilised has long been a vexed question, as the form of flower would seem to exclude self pollination. There is strong evidence of cross fertilisation on any plantation where two or more varieties are grown in neighbouring plots. The pollen might be carried by wind or by wasps, bees or other winged insects. Dr. von Faber of Java has shown, however, that self pollination is the rule, but that pollen can be carried by a breeze to flowers of a neighbouring tree with interlocked branches.

VARIETIES.

We have, then, just the one species of Theobroma of commercial importance, easily recognisable as one and the same tree in Ceylon, on the Gold Coast or the Antilles. It is only when we come to examine the fruit and seeds (usually termed pods and beans) that we are faced with sharp distinctions suggesting definite varieties. The finest type is the *Criollo*. Its name suggests that it is the native or creole Venezuelan type. Cultivated in the fertile valleys of the Venezuelan coast ("The Spanish Main") it was the first variety to be planted on the Islands, and from Trinidad was conveyed in 1834 to Ceylon. Here to this day may be found pure strains of Criollo cocoa, known on the London market as "old red cocoa" of Ceylon. The Criollo type is distinguished by a knobby irregularly shaped pod, broad at the stalk end often tapering to a decided point. The husk is comparatively soft and thin; there are ten distinct furrows, five deeper than the rest. The typical pod is red in colour. Of greater interest is the nature of the bean. The contents are white or pale pink in colour; much sweeter and less astringent in taste than any other variety. For this reason the Criollo bean is specially prized in the manufacture of the choicest chocolate.

We can clearly distinguish between this and the *Forastero* type (*i.e.*, foreign to Venezuela) but the Forastero shades off almost imperceptibly into the least valued type, sometimes classified as a separate variety, the Calabacillo (*i.e.*, the shape of a calabash). Under the name Forastero are classed the most widely cultivated kinds; they are distinctly hardier in habit than Criollo, giving an earlier first crop and heavier subsequent crops. One of the finest types of Forastero bears large pods, 9 to 10 inches long with a constriction at the stalk end and a warty surface. This is the *Cundeamor*. Near akin to this is the *Liso* or Trinidad Forastero, with a similar pod but without the constriction; the shorter, melon-shaped pod without constriction is known as the *Amelonado*. This type is widely cultivated in West Africa and elsewhere.

Each type occurs both as red and yellow fruit. All kinds of Forastero pods possess thick, hard husks but the furrows are not so deep, nor the ridges so pronounced as in the Criollo. The beans are decidedly flatter, the colour of the fresh contents varies from a light purple to a deep violet; this colour is always associated with an astringent taste. The poorest types of Forastero, conveniently classed as *Calabacillo*, bear a rounded pod, about 6 inches long with smooth surface scarcely lined with furrows. The beans are flatter and smaller than those just described, deep purple or slaty purple in hue and harshly astringent in taste. Any of the Forastero types hybridise and improve in the following generation when planted alongside Criollo trees.

FORMING A PLANTATION.

In establishing a plantation it is most probable that one of the better Forastero types would be selected. The small yield of the Criollo and its low resistance to disease prevents its exploitation on a large scale. The seed selected can best be planted "at the stake" *i.e.*, in the field; the rule being to plant three seeds and allow the strongest seedling to survive. The mortality of the seedlings is heavy—30 or 40 per cent. may succumb, so that it is customary to raise supplies in a nursery protected by a light cover of palm leaves. The pots are conveniently made of bamboo joints which are split open with a stroke of the cutlass on transplanting.

In selecting a site for a cocoa plantation we should, as already noted, seek a humid climate, a rainfall not excessive but well distributed, where there is no likelihood of prolonged drought nor quick changes of temperature. Many kinds of soil have proved capable of growing healthy prolific trees; best of all, rich alluvial loam, with free drainage. Soil soaked in brine or otherwise water-logged is quite unsuitable. The black vegetable mould of virgin forest land is especially esteemed and so are volcanic soils, rich in potash and phosphates.

The clearing of forest land is a formidable undertaking. Once the trunks are removed, the branches and stumps are burnt and the ashes forked in. Shade trees are planted if required and temporary shade for the seedlings. The crowns of the hills must on no account be stripped; they are left in forest to prevent the wash out of soil by the tropical deluge. Broad belts of trees are left between the clearings to act as wind-screens, for the cocoa leaf is singularly sensitive to high wind. In open country close wind-breaks are planted, choosing trees, if possible, of economic value, such as the Hevea or other rubber trees, the bread-fruit, mango, guava or other fruit trees, or even selected timber trees. Good drainage of the plots is absolutely essential; the usual plan being to run open drains into streams or ravines. Where the soil is loose a creeping undergrowth is necessary to hold up the sides of the drain. Catch crops are quickly established to shield the soil from direct sunshine and to provide the necessary temporary shade for the cocoa seedling. Tannias, cassava, chillies and pigeon pea are recommended. The destruction of organic matter (commonly described as humus) by the action of tropical sunshine on the bare soil is extraordinary. Bananas are universally planted in Jamaica and wherever there is a ready market for the fruit. Their broad leaves efficiently protect the young cocoa. Where conditions are favourable a crop of bananas may be reaped each year for 5 or 6 years, or until the cocoa trees cover the ground. Only when the catch crops are established and the land drained can the cocoa seedling be planted. The best variety of seed to select for propagation can only be determined by a careful study of trees in the locality, but in all cases (as will be shown later) it is important to plant ripe seed from the most prolific and vigorous trees.

It has been the practice in most of our colonies to plant *permanent* shade trees, but this has not been the case in Jamaica, Grenada, St. Lucia or Dominica where the cocoa is grown in volcanic mountainous districts and for the most part in valleys sheltered by high ridges. Two of the Erythrinas are commonly grown for shade in Trinidad and the neighbouring mainland; the variety grown on the hills (*Erythrina umbrosa*) blazes out in early spring into flame-coloured blossom. The favourite shade trees—Erythrinas, Samans, and others—are all leguminous trees, acceptable because the nitrogen-fixing bacteria of their root nodules arrest the exhaustion of the soil, while their flowers, pods and leaves supply a rich mulch.

A network of fibrous roots holds together the soil of an old cultivation and leaves little room for the growth of weeds, but in younger plots the practice has grown up of clearing the weeds two or three times a year and lightly forking them into the soil, with or without lime. Mr. Joseph Jones, of the Agricultural Station, Dominica, has established beyond doubt the great advantage of heavy mulching with grass, weeds and leaves. In this way he obtained better and more profitable yields than with dressings of a complete artificial manure, up to 80 per cent. in excess of the unmanured plot. It is not customary to carry much live stock on a cocoa estate, but the manure from draught oxen, horses, mules and pigs, is of special value under tropical conditions where the decomposition and wastage of humus is extremely rapid and where the building up of a spongy soil is necessary to retain moisture. Green mulching may be regarded as supplementary to pen manure. The vegetable mulch may be greatly enriched by forking in a crop of any low-growing form of leguminous plant.

Manuring.—The accumulated experience of field trials, continued for at least twenty years, shows that the soil nutrients required by the cocoa tree are similar in character to those required by our fruit trees. Elaborate calculations have been made of the quantity of each nutrient carried off annually in the crop, but such calculations are of small value in determining the quality and quantity of manure required. Direct experiment is necessary in the field. If this is true in our climate, how much more in a climate where the breakdown of rotting vegetation to form available plant material and even the weathering of soil takes place with great rapidity. It is often found unnecessary to supplement the available supplies of nitrogen, phosphate and potash, for many years in succession. Supplies of *nitrogen* are well conveyed in the form of sulphate of ammonia, dried blood, guano or cotton seed meal. On most soils nitrate of soda does not react so well as the ammonium salt. Where supplies of wood ashes fail, *potash* is best given as the sulphate. *Phosphate,* in the form of basic slag, reacts favourably on the trees for at least three seasons and is widely applied. A dressing of *lime* or ground chalk has proved invaluable on most estates.

Forking.—In the absence of permanent shade trees, forking or light hoeing of the soil becomes specially important with a view to retaining humus and arresting evaporation. This should naturally be done at the beginning of the dry season.

Pruning.—I can only touch lightly on pruning, a subject dear to the heart of every planter. Johnson defines the main object of pruning as the production of symmetrical trees with the maximum quantity of fruiting branches; the admission of air and light to all parts of the tree; the removal of gormandising suckers from the main stem, and, generally, to encourage a spreading habit which enables the fruit to be more readily harvested. The severe pruning of former days has been replaced by light pruning at frequent intervals.

For a detailed account of the methods of cultivation, reference must be made to three admirable text books which have been drawn upon in preparing this address :—*Cocoa,* by Dr. Van Hall of the Institute at Buitenzorg, Java ; *Cacao, its Cultivation and Curing,* by the late J. H. Hart of Trinidad ; *Cocoa its Cultivation and Preparation,* an Imperial Institute Handbook, by W. H. Johnson, formerly of the Gold Coast and South Nigeria. For information on diseases of the cocoa tree see W. Nowell's work, "Diseases of Crop Plants of the Lesser Antilles," recently published by the West India Committee.

Harvesting the Crop.—When the pods are ripe, those on the trunk and lower branches are easily detached by a clean cut with the universal tool of the country, the *machete* or cutlass. The branches are too brittle to allow the pickers to climb, so that fruit from the upper branches is cut down by a hooked knife, attached to a bamboo pole, serving equally well for a push or pull cut. Great care is required to protect the cushion from which the pod springs ; once damaged no further flowering can take place at that point.

Breaking.—The ripe pods are collected in heaps and broken by a slash with a cutlass, which penetrates partly through the husk, the pod being snapped across by hand. The beans should be taken out by hand and separated from the placenta or "heart" which is thrown to one side, along with the husk. Each pod contains from 30 to 40 beans. The beans and the white pectinous mass of pulp surrounding them are then placed in clean baskets, covered by banana leaves and carried to the fermenting house.

Yield.—Three cwt. of dried cocoa beans to the acre may be considered an average yield for estates good and bad. Given a planting distance of 12 feet this only represents an average of 14 pods a tree, or 1.2 lbs. of dried cocoa. Average yields of 5 to 6 cwts. to the acre are attainable on fertile soils, and double this on selected plots. Thus Carl de Verteuil of La Vega, one of the most experienced planters in Trinidad, obtains crops of 12½ bags (or 170 lbs.) per 1,000 trees, or approximately 5½ cwt. dried cocoa to the acre. One splendid old tree, used for propagating at La Vega, yielded 670 pods in 1917 (55 lbs. dried cocoa); 359 pods being collected at a single picking.

Diseases.—Of the many mammals, insects and fungi that prey on the cocoa tree we can only refer to the more important.

Fungi.—The *brown root* disease of Ceylon and West Africa can often be extirpated by re-draining the land, after burning infected roots and disinfecting the soil. A more wide-spread fungoid disease, found both east and west, is the well known *canker* (*Phytophthera faberi*) attacking trunk and branches and giving rise to the *black rot* of pods in the West Indies, identical with *brown rot* of Ceylon. Moist spots appear on the trunk which darken and exude gum. The fungus may penetrate into the wood giving reddish patches. At a later stage the whole patch can be cut out with a knife. It is a curious fact that *canker* and *black rot* are seldom found together on one and the same tree. In the Antilles, a vigorous fight is maintained against *die-back,* the cocoa *Diplodia,* a deadly fungus found everywhere. It first attacks the extremities of the branches and, if left alone, will strip the tree of its leaves before killing it. It often follows an attack of thrips.

Insects.—Of insects, probably the group of *borers* is the most deadly, more particularly the larvae of beetles. Beetle traps are employed with some success on plantations. In Ceylon a well known *helopeltis* attacks both twigs and pods. This has been exterminated in several cases by introducing nests of the black ant. In the West Indies a most dangerous insect is the small cocoa thrips, which strips the leaves and may even kill the tree.

Side by side with the direct attack on disease attention has been concentrated, in recent years, on promoting the vigorous growth of the tree by enriching the soil and clearing it of weeds. This has proved remarkably successful. In Dominica I have seen a young plantation, where trees were failing and diseased, restored to full health by careful tillage of the soil and provision of adequate cover from sun and wind ; all gaps being filled with tephrosia or pigeon pea. Cocoa thrips and, in some cases, *canker* can best be fought on these lines. On the other hand *canker* and *black rot* are often cured by removing excessive shade and letting in air. The obvious line of attack on the borers is to cut out all dead branches and diseased limbs ; to burn the refuse and tar the wounds. This will also restrict the breeding ground of the *die-back* fungus. Other obvious precautions include the removal of rotting trunks of trees from the site, and sprinkling the heaps of pod husks with lime, preferably quick lime, before burying them in shallow trenches.

Along with these methods of sanitation spraying must not be neglected, preferably with Bordeaux mixture, sprayed on the leaves and immature pods to protect them from fungoid disease and to kill any existing fungus.

Mammals.—Rats and squirrels are a pest on the Gold Coast and elsewhere. One mistaken attempt to exterminate rats had extraordinary consequences in Jamaica. Fifty years ago a worthy Governor introduced a big species of rat to eat up the native rats, which it did with avidity, and then fed on the fat of the land. His successor brought mongoose from the east, which, after cleaning out the rats, raided hen roosts and insectivorous birds' nests. In the absence of birds, ticks and other insects became a serious scourge, attacking all and sundry, even infesting and destroying the mongoose. The birds are now coming into their kingdom, and the balance of nature is being restored.

Agricultural Departments.

The industry is greatly indebted to the agricultural departments of the several Colonies. It has benefited by their active propaganda in favour of more scientific methods of culture, conducted both by demonstrations on the plantations and by extended field trials. The Trinidad Department, under the Directorship of Mr. W. G. Freeman, took the bold course of purchasing a derelict plantation—the River Estate—which it has developed into a valuable property. Here the more urgent problems of the industry are being solved by carefully devised experiments. Let us discuss a few of them to illustrate the valuable work done by the Departments.

(1) *Planting Distance.*—Plots have been established with trees planted at all distances from 6 to 18 feet. The results obtained show that closer planting produces earlier and heavier yields, and justifies the modern practice of planting at 10 to 12 feet, rather than at 14 or 16 feet intervals. Unlike the orange or lime tree it is no disadvantage for the branches to interlock slightly, giving that partial shade which favours good bearing.

(2) *Permanent Shade.*—For years the practice of shading cocoa with the quick growing Erythrina has been the subject of hot debate amongst planters. It has been definitely established at River Estate that full shade, as practised in the Island, with an Erythrina at 28-30 feet intervals, encourages *canker* and *black rot.* A condition of partial shade, however, *e.g.* an Erythrina planted every fourth row, at 56ft. intervals, favours heavier crops than are given by unshaded trees. As this idea wins acceptance, planters are beginning to cut out alternate shade trees in the older cultivations, a most difficult undertaking.

(3) *Bearing Capacity.*—Individual records of 1300 trees show that the annual crop of pods varies enormously. Thus two neighbouring trees of the same age and variety, over an eight year period, gave an average yearly output of 54 pods and 2½ pods respectively. Special manurial treatment has an all-round beneficial effect but does not convert poor or medium-bearing trees into good bearers. Heavy bearing appears to be a matter of heredity, hence the great importance of selecting seed for propagation. This fact was not taken into account in the older manurial trials, on small plots, and renders them of comparatively little value. All manurial trials are now preceded by recording details of the growth of the tree and crop yielded for some years under natural conditions. Trials are being made to eliminate poor bearers by cutting them down two feet from the ground, allowing a sucker to shoot up from the ground and budding from a heavily bearing tree.

(4) *Budded and Grafted Plants.*—Grafting by approach is considered too difficult an operation for estate work; moreover there is no chance of renewal if it fails. Patch-budding is simpler and patch-budding at the stake proves more certain than budding in the nursery. Judging, however, from the latest published results it seems probable that seedlings will prove earlier and heavier bearers than budded stock. Elsewhere, budding a fine Criollo variety on a hardy Forastero stock has given good results.

Enough has been said to indicate the fruitful lines of research undertaken by scientific advisers on Agriculture in the Colonies. They deserve all praise for revivifying old, introducing new industries and equipping defence forces to arrest the ravages of plant diseases. It is encouraging to find that the scientific equipment of the Colonies has just been strengthened by founding a tropical Agricultural College in Trinidad. The Staff of the Imperial Department of Agriculture has been absorbed by the College, and the Commissioner, Sir Francis Watts, has become its first principal.

It is under the control of a Board of Governors, sitting in London. The College gives unrivalled opportunities for research on the unsolved problems of cocoa cultivation, while training the coming race of planters and researchers.

It has already attracted post-graduate students from distant countries.

CURING THE BEAN.

(1) *Fermenting.*—A variety of receptacles are employed for the process of "sweating" or fermenting the bean. The simplest plan is to be found in Ceylon, where the mass is heaped on the floor, covered with banana leaves and stirred from time to time. In West African Colonies, floors, barrels, packing-cases, and properly constructed boxes are made use of. The tanks or "sweat" boxes used in Trinidad are large pitch-pine structures (*e.g.* 6 x 6 x 3 feet), often built in sets of six, and embedded in concrete. Each box can carry the contents of 40,000 pods, the equivalent of 30 cwt. of dried cocoa. The solid wood bottom of the tank is pierced with holes, and supports a wooden grating, on which the mass stands. It is customary to turn the fermenting cocoa from one box to another on the second, fourth and sixth days, turning it out to dry on the eighth day, but some planters prefer a six day fermentation. The method I would more closely describe is based on that long practised in Grenada, and recommended for adoption in West Africa. The box is smaller, carrying the contents of 8,000 to 16,000 pods, made of 1½ inch timber, fastened with copper nails, it carries a false bottom perforated with a number of holes. The cocoa is covered with banana leaves and a perforated lid closes the box, the drainings or "sweatings" run out through holes in the under space. It will be seen that this arrangement makes it possible to control the aeration of the mass. The boxes are arranged in rows in a low "horse." The floor should be finished in smooth cement, sloping to a gutter and both floor and boxes should be frequently swilled out. We discuss later the exact nature of the fermentation process.

(2) *Drying.*—From the "sweat" house comes a mass of hot beans, still coated with a residue of brown, slimy pulp. In Ceylon, the beans are washed at this stage to give a clean shell and bright colour. In the other Colonies the cocoa is turned out to dry without further treatment.

The Trinidad Government has just legislated against the practice of rubbing the damp beans in red ochre or red clay to impart a uniform appearance to the shell.

Drying in the sun and wind is still the rule where the climate allows, but an artificial drier is a valuable insurance against loss in the rainy season. The older sun-driers take the form of large cement or paved courts, called barbecues. The favourite sun-drier in Trinidad is a fixed wooden floor with a sliding roof. When the floor is covered, drying is sometimes continued by means of hot air or hot-water pipes, running under the drying floor. In Ceylon, a hot-air apparatus of a simple character is universally employed for drying cocoa in the rainy season. Air from a stove is drawn over the beans by a powerful fan, in a cheaply constructed drying house. The smaller estates on the Islands use wooden trays on wheels, running out on rails from the shelter of the drying house. The beans are raked over regularly; a slow and uniform drying results. The beans are heaped the first night, when they are still damp enough to allow fermentation to take place. Before the mucilage is dry, the beans are often rubbed by hand or polished by "dancing" with bare feet, to improve the appearance. This curious process is seen to advantage in my slides.

Drying by artificial heat has to be carefully adjusted to avoid quick and uneven drying. A favourite form of drier is the "Guardiola," consisting of a horizontal rotating drum, fed with hot air through a system of tubes. It is best adapted for completing the drying, after the beans have been exposed to the sun for a day or two. This is only one of a variety of mechanically operated driers.

LECTURE II.—*Delivered November 19th,* 1923.

We may now briefly consider the position and prospects of the cocoa industry in our several Colonies.

Trinidad.—It has long been recognised that Trinidad has an almost ideal climate and soil for the culture of cocoa. The fact that the island lies well outside the usual track of hurricanes gives the planter confidence. Trinidad lies 10° North of the equator with an average rainfall ranging from 65 inches on the coast to 100 in the hills, and a humid atmosphere. The best plantations are to be found in well protected and well drained valleys, with deep alluvial soil, covered with a rich deposit of mould. Cocoa also grows well in a brown loam, known as chocolate soil. It is not considered remunerative to plant above 800 or 1,000 feet. The ubiquitous Erythrina, miscalled the Immortelle, towers high above the cocoa groves; its light foliage gives an agreeable shade, in contrast to the scorching sunshine of the sugar fields. The discovery of extensive oil fields underlying the estates has enriched some of the planters, but should not lead to the destruction of many trees. The presence of a large East Indian population makes it possible to secure good agricultural labourers, willing to give a full week's work, and this in turn reacts on the negro. Many of the estates have been planted under a contract system. The contractor is bound to plant a given number of trees and is allowed to take catch crops for his own use, usually for a four year period, at the end of which he cleans the land and hands over the established plantation. Many planters now prefer to avoid the obvious risks involved in such a system and employ direct labour, which is always paid by the task. The plantations contain every variety of Forastero (including Cundeamor, Liso and Amelonado), but only isolated survivors of the older Criollo culture.

The relative importance of the British West Indian Islands as cocoa producers may be shown by taking the average of the 1921 and 1922 crops. They are quoted in short tons (2,000 lbs.).

Trinidad	36,000
Grenada	4,500
Jamaica	4,200
St. Lucia	750
Dominica	350

It will be seen that only the more mountainous islands, with rich volcanic soil, figure in the list.

Grenada, the beautiful Spice Island, is mainly given over to the cultivation of cocoa and nutmeg, on plantations rarely exceeding 50 acres. Here cocoa is grown without shade, and nowhere is the tillage and manuring of the soil better understood, nor the trees better cared for. Close planting is the rule and the yield per acre is unusually high. Sheep or cattle are kept to provide pen manure. A fifth of each plantation is reserved for pasture and arable. It is claimed that the absence of shade trees saves much expense while the cocoa comes earlier into bearing and gives a higher yield.

Jamaica.—The present culture has only been established 50 years and has grown with the rapid extension of the banana trade. Cocoa has been extensively inter-cropped with bananas; this applies more particularly to the sheltered valleys north and south of the Blue Mountains. Hurricanes and strong "Northers" have played havoc with the plantations in Jamaica as well as in Dominica and St. Lucia.

Ceylon.—Until Sir Arthur Gordon opened up the Montserrat district, in 1868, only some 7,000 acres were planted in cocoa. The planting was rapidly developed by resident proprietors, between 1870 and 1880 at a time when a leaf disease was leading to the wholesale destruction of coffee plantations. No export trade was attempted until 1878. By 1890, the export amounted to 1,000 tons and in 1905 to 3,200 tons. Since that date there has been no marked increase. Over 2,000 estates include cocoa amongst their crops, but the total area in cocoa is only 30,000 acres. All these estates are situated in the moist districts, where the rainfall varies from 75 to 120 inches. Much of the island lies above the 2,000 feet level and therefore is adapted for tea culture rather than for cocoa. When the Criollo trees of the original strain were attacked by helopeltis and canker, Forastero seed was planted, in the expectation that this type would prove more resistant, but the diseases are still rampant and tend to restrict the crop. Bananas are not used for shade, the dadap (Erythrina lithosperma) is preferred both for temporary and permanent shade. Cocoa and Hevea (rubber) are often planted in alternate rows at distances of 20 feet.

Nigeria.—Cocoa is said to be grown but not cultivated in Southern Nigeria. We learn from the same source, that it grows in spite of the mishandling to which it is subjected.* The culture is extending from the West province to the Central Province. Climate and rainfall are entirely suitable in the rain forest belt. The native does not grow cocoa under shade. His primitive methods of culture involve pruning with a cutlass, and manuring the tree with its dead leaves and weeds. In pre-war times when the native could produce at 10s. per cwt. and sell at 40s. to 50s., it was difficult to persuade him to cultivate and cure his cocoa properly, but lower prices and the increased cost of labour seem likely to provide the necessary stimulus. The Amelonado type of cocoa is grown; the quality of the bean is probably as good as that of the Gold Coast but it lacks proper curing and grading for market. The able governor, Sir Hugh Clifford, and Mr. O. T. Faulkner, Director of Agriculture, are alive to the importance of these factors in securing a proper place for Nigerian cocoa, in the world markets. Small co-operative fermenteries, equipped with the simplest of appliances, are being set up and these will doubtless have an educative effect. The crop has increased by leaps and bounds and exceeded 30,000 tons in 1922.

---

* Trade relations between Canada and Nigeria. Report of 1920.

Gold Coast.—In 1918 to 1919 Mr. W. S. Tudhope, Director of Agriculture, undertook a journey of 2,000 miles through the cocoa districts, and his report presents a vivid picture of the present condition of the industry. In the course of 20 years the output of cocoa grew from a single bag in 1891 to 35,000 tons in 1911, when it eclipsed that of any single country. In 1919, the export reached the unprecedented figure of 176,000 tons, valued at 8¼ million sterling, a figure swollen by part of the 1918 crop, held back for lack of shipping facilities. So remarkable a growth of an entirely new industry can have no parallel in the history of the negro race.

The rapid expansion of the culture on the Gold Coast, where the tree is grown by the native in small holdings, has often been compared with the relatively slow development in the Cameroons, where big estates were laid out under scientific control.

Mr. Tudhope points out that the closely planted trees are beginning to deteriorate at 20 years of age. Diseases are rampant, both insectivorous and fungoid. There is a serious increase of *brown pod* disease (phytophthera), and *thread blight.* When a farm is badly attacked, it is the universal practice to abandon it, and let the intervening bush smother the trees. After two or three years the plot is cleaned up, with more or less satisfactory results. In any case the farmers tend to abandon the older farms and carve out new plots from virgin forest. Mr. Tudhope views the wholesale slaughter of forests with alarm, in a country where the rainfall (near the coast) is only 45 inches. The railway tapping the cocoa districts has been pushed up country and now extends 67 miles from Accra, the cocoa port. A time will come when low prices, increased cost of labour, and heavier charges for freight will force the farmer to remain on his plot and enrich the soil by manuring and proper tillage. The agricultural officers at Aburi and elsewhere are making a bold stand in favour of better methods of culture and curing. They have succeeded beyond expectation in persuading the farmer to ferment his cocoa. Motor traction is taking the place of head loads and the cumbrous barrels, but these are still to be met with on the up country roads. The economic position of the industry was badly shaken by war conditions. The restriction of shipping nearly caused its collapse, coupled with the control of prices in 1918. The relative values assigned by the food controller at the time were: Ceylon 100s., Trinidad 90s., Grenada and other West Indian sorts 85s., and British West African 65s. Then came the years of soaring prices, followed, in 1920, by a sudden crash. In the course of a year, Accra cocoa fell from 130s. to 42s. cwt. The price offered to the farmer was so trifling that he left his pods to rot on the trees, thus adding more breeding grounds for fungoid disease.

Everywhere, to-day, with the exception of certain Ceylon estates, the planter is faced with an impossible situation; owing to the low prices prevailing he can no longer produce cocoa at a profit.

WORLD PRODUCTION AND CONSUMPTION.

Since the beginning of the century, the world's production of cocoa has almost quadrupled, and the consumption has more than kept pace with it. The figures are:—

	Production.	*Consumption.*
1900 ..	102,000 tons.	100,000 tons.
1922 ..	374,000 „	411,000 „

It will be seen that the increase is largely met by the West African crop.

The Imports of cocoa into the chief-consuming countries in 1922, may be compared with those of a pre-war year, 1913. Although not accounting for re-exports, these figures give an indication of the rapid increase in the quantity of cocoa consumed.

IMPORTS.

	1913. metric tons	1922. metric tons
U.S.A.	67,600	150,700
Germany	51,000	84,000
United Kingdom	27,500	51,300
France	27,700	38,500
Holland	30,000	36,000

APPENDIX.—NOTE ON THE FERMENTATION PROCESS.

To understand the nature of the process we must study the composition of the sweet pulp that surrounds the beans. The pulp, by the way, possesses a delightful sub-acid flavour. It contains from 8 to 13 per cent. of solid matter of which 5 to 9 consists of sugars, both invert sugar and sucrose. The free acid present is tartaric acid (1 to 2 per cent.) The albuminoids (0.5 to 0.7 per cent.) are present in sufficient quantity to promote the growth of micro-organisms. We have here an ideal medium for an alcoholic and subsequent acetic fermentation. That such spontaneous fermentations take place is evident to the senses and is shown, beyond doubt, by analysing the drainings from the pulp. Here, for instance, is the composition of the first runnings from a fermenting box in Jamaica drawn 15 hours after breaking the pods.

Total solids	5.8 per cent.
Mineral matter	0.5 „
Invert sugar	3.5 „
Pectin	2.0 „
Alcohol	4.9 „
Total Acidity (as Acetic acid)	0.8 „
Volatile acid (as Acetic)	0.6 „

This will serve to illustrate the fundamental changes that have taken place. Remember that the liquor penetrates into the beans which become saturated with the products of fermentation, profoundly affecting their flavour, although the shell membrane is fine enough to prevent any micro-organisms from percolating to the kernel.

The following description is based on a close study of hundreds of fermentations in the West Indies:

The beans and adherent pulp, which are commonly at a temperature of 26 to 28° C. when placed in the box, rapidly become warmer. During the first 24 hours the temperature rises to 35 or 40° C., varying with the position in the box. Within 48 hours it rises to 40-45°C. If the fermentation is continued for 5 or 6 days the temperature will be found to rise to a maximum of 45-50° and maintain this until the 8th or 9th day. Higher temperatures are occasionally noted, but they rarely exceed 53°. If the fermentation is continued for the exceptionally long period of ten to eleven days, as is the custom on certain Trinidad estates, the temperature will fall slightly towards the close. While the process is going on the bean and adherent pulp change from white or pale pink to a rich brown colour; characteristic odours are evolved and a most vigorous fermentation takes place. Although the fermentation is spontaneous, it follows a definite course if the boxes are not infected and the aeration is sufficient. We can distinguish three clear stages. First, a feeble alcoholic fermentation, due to organisms that were growing on the surface of the pod. We always note a strong growth of saccharomyces apiculatus, together with smaller quantities of sacch. anomalus and other "wild" yeasts. This stage lasts about 12 hours. Secondly, as in spontaneous wine fermentation, an enormous development of true saccharomyces occurs exhibiting typical oval and round cells. If the temperature rises normally, no formation of new cells is noted, after the first 48 hours. The alcohol produced soon arrests the growth of saccharomyces apiculatus and the "wild" yeasts. At this stage a quantity of alcoholic liquor drains away. The third stage of fermentation is characterised by a great growth of acetic acid bacteria. In addition to air-borne bacteria, masses of these are conveyed to the boxes by swarms of the little brown "vinegar fly." (Drosophila). They carry the bacteria from their last meal of rotting fruit. The mixing of the mass every second or third day ensures the presence of acetic acid bacteria in every part of the fermenting mass, where both temperature and degree of aeration favour rapid growth. The drainings now consist of dilute vinegar. If the temperature does not rise above 50°, the acetic organisms continue to grow during the remainder of the fermentation. In the rare cases where fermentation is prolonged beyond eight days, a fourth stage is reached with a vigorous growth of spore-bearing bacilli, of the bacillus subtilis type. As fermentation progresses the change of odour is marked. The sweet, fruity and mildly alcoholic odour of the early stage changes, first, to a strongly alcoholic, and then to an ethereal odour suggesting ethyl acetate. Later a strong acetic acid odour supervenes, but this is always accompanied by fruity ethereal components. Finally if the fermentation is prolonged until putrefactive organisms predominate, an odour resembling that of high game is evolved.

Although it seems on the face of it extremely improbable that such a crude process, in an atmosphere charged with germs, should give a normal sequence of fermentations, yet this is undoubtedly the case. Abnormal fermentations are seldom noted, if the fresh beans are immediately conveyed to the boxes with due regard to cleanliness, if the mass is not diluted by rain in transit, and if the degree of aeration is under control. A cold diluted pulp will favour the growth of moulds and an insufficient air supply the growth of putrefactive bacteria. In either case the process must be stopped at once and the beans dried off.

The conditions allow of the growth of any of the true yeasts derived from the air or from the surface of the husks (provided they can exist at the high temperature of the mass) without any noticeable fluctuation in the character of the product. It would seem, therefore, beside the point to suggest, as Preyer has done, that a specific type of yeast is required to bring about a normal cocoa fermentation. In its earlier stages the process may be likened to a spontaneous wine fermentation, but, whereas the quality of the wine is almost entirely due to the products of fermentation, the quality of the fermented cocoa is dependent on a series of internal chemical changes, although the eventual flavour is modified by the residual products of the pulp fermentation.* Putting on one side some of the more obvious effects of the external fermentation, *e.g.*, the removal of the greater part of the pulp, and the loosening of the seed from its testa (causing it when dry to break up easily into nibs), let us consider more closely the improvement in flavour and colour. The primary effect of fermentation is to kill the seed, a change accompanied by the destruction of plant tissue, the liberation of enzymes, and the beginning of chemical activity. Sack, in Surinam, has shown that exposure to a temperature of 44°C. for 6 hours is sufficient to kill the embryo. This temperature is commonly reached on the 3rd or 4th day and coincides with the development of enzyme activity, while the optimum temperature for the enzymes 45°-60°C. is reached in the latter stages. It may be recalled that the oxidising enzyme (*oxidase*) is only destroyed at 75°C.

Our knowledge of the cocoa enzymes is derived from the work of Oscar Loew of Porto Rico, and Harvey Brill of Manila. Brill finds a greater number of enzymes in the pulp than in the fresh bean, but these percolate into the bean during the process. He finds no evidence of fat-splitting nor glucoside-splitting enzymes, but he finds the proteolytic enzymes (casease and protease), and large quantities of oxidase in the bean and pulp. Invertase, diastase, and raffinase are present in the pulp and fermented bean. How far can we trace the effect of their activities on the constituents of the bean? The cocoa butter is hardly affected, but the albuminoids are attacked to a slight extent, as shown by a decrease of proteid and an increase of the amino acids. The total loss of dry material is trifling. Although the evidence has been criticised, it will be convenient to regard the most important chemical change as the breakdown of a complex glucoside (Schweitzer's cacaonine) into glucose, cocoa-red and theobromine, the white crystalline alkaloid. This presupposes the absorption of oxygen. This, or a similar hydrolysis occurs, but the reaction is only completed when the bean is heated to the roasting point. Schweitzer's equation cannot be accepted in its original form, becuase it does not account for the production of the essential oil. By distillation of many cwts. of roasted cocoa nibs it proved possible to isolate enough essential oil to determine its composition. It has an extremely powerful odour and is undoubtedly the true aromatic body. As it constitutes less than 1 part in 100,000 of the bean, it is not surprising that it long escaped the notice of chemists. The liberation of cocoa-red accounts for the marked change of colour. It exists in two forms, a bitter soluble substance which readily oxidises during fermentation into a reddish brown, insoluble and therefore tasteless form. The series of reactions described above would account for (a) the reduction of astringency, (b) the increased sweetness, (c) the production of aroma and (d) the change of colour. While much work remains to be done on the problem it is clear that the development of fine flavour, aroma and colour, owes less to the direct products of fermentation, than to the products of enzyme activity. Two or three days' fermentation is sufficient to complete the desired change in flavour in the fine Criollo bean, whereas a full 8 or 9 days is commonly required with the Amelonado type. Six days is the standard time in West Africa.

---

* These products are not entirely removed by roasting; when roasted nibs are steam distilled, small quantities of ethyl acetate, propionate and butyrate are found in the distillate.

FOREST RESOURCES OF CHILE.

Amongst the many natural resources of Chile due prominence must be given to its forests. According to the annual report* on the financial and industrial conditions in Chile, by H.M. Consul-General at Valparaiso, the Southern zone is practically covered with forests, the most important being found from latitude 37° to 44°. The area covered is calculated at 75,000 sq. miles, which corresponds to approximately 26 per cent. of the total area of the country. There are considerable tracts of forest land beyond these limits, but the timber, both in quality and quantity, is not so good. Amongst the principal classes of timber exploited commercially may be mentioned rauli, laurel, radal, avellano, roble, lanque, corque, manio, sauce, etc.

Rauli (*Nathofagus procera*) is one of the most important classes of timber handled. It abounds in the provinces of Cautin and Malleco. The wood is of red colour, veined, medium weight, practically free from knots, and dries fairly rapidly. It is used for building and for furniture and is excellent for making staves or barrels. Well selected, it makes a first-class parquet.

Roble Pellin (*Nathofagus obliqua*).—This Chilean red oak is very largely consumed throughout the country and exists between latitudes 38° and 42°. The wood matures very slowly and is used in construction principally for beams and supports. It is also used in the building of barges and for railway sleepers.

Alerce (*Fitzroya Patagonia*) is a gigantic tree which thrives in the swampy districts south of Valdivia. Specimens are found measuring 60 feet high by 5 feet diameter.

The wood has the characteristic of not being affected in the least by moisture, and, indeed, it is largely used in the south of the country for roofing purposes. It is not necessary to replace an alerce roof for 80 or more years.

Coicue (*Nothofagus Dembeyi*) is very abundant in the southern regions and is used for all kinds of construction It is useful for railway sleepers.

Cypress de Cordillera (*Libocedrus Chilensis*) is found from latitude 30° south. It is light in weight and pale yellow in colour, and is used largely for furniture.

Cypress de Guaytecas (*Libocedrus Tetragon*) is found to the south of Valdivia, but abounds in enormous quantities on the different islands between 42° and 46°. The wood is hard and very resistant against water and is used for sleepers in damp regions.

Lingue (*Persea Lingue*) is found from Llanquihue in the south and as far north as Atacama. It is used in construction works, but its principal use is for furniture. It possesses a rich coloured vein which enables it, when varnished, to be made to imitate all classes of fine wood, such as walnut, jacaranda, cedar, etc.

Laurel (*Laurelia Aromatica and Laurelia Senata*).—This tree abounds from latitude 34° to the island of Chiloe. It is used for floorings and ceilings, but selected wood is used for parquet and furniture. Like the lingue it adapts itself to all kinds of varnish.

Litre (*Litre Cautica*) is found throughout the country. It is used for making cart wheels and spokes.

Luma (*Mircongenia Luma*) is obtained in the central and southern zones. Of a red colour, it is exceptionally hard and heavy and is able to withstand enormous strain.

Maniu (*Podocarpus Chilena*) is very durable, aromatic and of yellow colour. It is used for furniture, flooring and construction of masts and spars.

Tique (*Aextoxicum Punctatum*).—This tree is found in the swampy regions of the south. The wood is very durable, and is largely used for naval construction.

Pehuen (*Araucania Imbricata*) is to be found between 37° and 40°. After alerce it is the tallest tree to be obtained in the country. It is used in delicate carpentry work. The fruit produced by this tree (piñon) is reputed to be valuable for medicinal purposes, as is also the bark.

Quillay (*Quillaja Saponaria*) is obtained between Coquimbo and Valdivia. The trunk and branches are used for firewood and for making charcoal, but the bark, which is useful for certain chemical purposes, is exported in large quantities.

Algarrobilla (*Caesalpina Brevifolia*) is a shrub peculiar to the Atacama and Coquimbo districts. It produces an excellent firewood, but is chiefly valuable for the berry which it bears and which is used for tanning leather. With the exception of about 100 tons consumed in the country in the leather industry, the whole production is exported to Europe. The crop varies from year to year, sometimes amounting to 4,000 tons and at other times to only 300. Experiments have been made to transplant this shrub in other countries, and even in other districts of Chile, but so far without success.

* * * *

The Government is beginning to take an interest in the forests, and facilities are afforded to those desiring to plant trees. The various agricultural societies sell annually some million of plants, principally eucalyptus and cypress, with a view to re-wooding grounds which in the past have been sadly neglected. This planting of saplings is not confined to the southern provinces, but is usual throughout the central zone and as far north as Coquimbo.

In general, it may be stated that the forests of Chile form one of its most valuable possessions. Added to this is the fact that private enterprise has been awakened, and plantations of eucalyptus, cypress, and poplars have been springing up throughout the country. Although there are several concerns engaged in the industry, only a very small portion indeed of the tracts of forests have been touched. There are innumerable difficulties in the way of transportation owing to the lack of roads and rivers capable of rafting the lumber to the coast, but when these matters receive adequate attention from the Government, Chile will take an important place in supplying the lumber requirements of its South American neighbours.

---

* Published by H.M. Stationery Office. 2s. net.

Apart from the general idea of the exploitation of lumber as lumber, the Chilean forests open an important field for the manufacture of wood-pulp.

JADE, AMBER, AND PRECIOUS STONES IN BURMA.

Burma is famous for its jade. The greater part of the jade of fine quality, however, is exported to China, whose fondness for the apple-green tinted jade is well known. It is therefore disappointing to tourists who visit Burma expecting to find plenty of jade of the first quality for sale at a reasonable price to learn that the best is taken by the Chinese market, which will pay even higher than tourist prices. Moreover, writes the United States Consul at Rangoon, the jade carved in Burma is rather crudely done, in comparison with the neat and beautiful work of the Chinese, which has become so popular for jewellery. Burmese settings are always of yellow gold, so that the jade is made almost ugly by both carving and setting.

The production of jade from April 1, 1921, to 31st March, 1922, amounted to 3,815 cwt. valued at 701,673 rupees (about £46,800).

Burma has only a small output of amber and that produced is not considered by experts to be as desirable as Baltic amber, being harder. It is found in clays of probably the Miocene age. There is little variety in the colour, which is bright cherry yellow with a reddish tint that fades into a dirty brown. It is used in the manufacture of rosaries and Burmese ornaments. Little is exported save in the form of beads, which are pretty and effective but not generally popular even in Burma.

No companies are working the jade and amber mines situated in the Hukong Valley. They are in the hands of chiefs of the area and at present are operated entirely by native methods. Jade and amber are also found in the public forest land of Upper Burma particularly in the Myitkyina and Upper Chindwin districts. The right of assessing and collecting royalty on the output of the public forest land is granted by license, at present held by a Chinaman.

Next to petroleum rubies are the most valuable mineral product of Burma. They are found in a variety of places—at Manyaseik, in the Nyitkyina district; in the stone tract of the Sagyin Hills, in the Mandalay district: and in small quantities in a few other places. The only place, however, where the returns are really profitable is the Mogok area, about 90 miles north-east of Mandalay. The ruby tract proper, consisting of mines at work and those abandoned, extends to about 66 square miles. The area in which mines are in active operation covers 45 square miles.

The latest figures available for the production of amber, jadeite, rubies, sapphires, and spinels in Burma are for the year 1921, and are as follows:—

Items.		Amount.	Value.
			Rupees.
Amber	cwt.	26,357	16,843
Jadeite	do	3,815	701,673
Rubies	carats	112,197	691,209
Sapphires	do	48,916	57,232
Spinels	do	32,802	14,027

"KILIM" CARPET INDUSTRY OF POLAND.

The "kilim" is a handmade carpet of wool on a ground or foundation of flax or hemp which, it is claimed, adds very greatly to its durability. The patterns may be generally divided into two categories those with geometrical figures, used for carpets, and those with designs of flowers and animals, for wall decorations. The carpets are made in the usual sizes, and as large as [illegible] by 20 feet. For richness of colour and quality of weaving, reports the United States Consul at Warsaw, the Polish "kilims" of the better grades can be compared favourably with Persian carpets, and also have the advantage of being less expensive.

The present yearly output is approximately 80,000 square metres (1 square metre + 1,195). This amount is produced on approximately 3,000 looms, and fully 75 per cent. of it in homes by weavers who have learned the art from their ancestors. The largest workshop has only 20 to 30 looms.

Prior to the World War the surplus production was marketed in Vienna, but since 1920 small quantities have been exported to England, France, Belgium, Italy and Switzerland. It is claimed that the present production could be increased by 400 or 500 per cent in the course of a year. The producers have no central selling organization but sell their products in small quantities as they are finished. Producing centres are reached easily from Warsaw.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

January 30.—Sir Richard Arthur Surtees Paget, Bt., "The History, Development and Commercial Uses of Fused Silica." Sir Herbert Jackson, K.B.E., F.R.S., will preside.

FEBRUY 6.—EMASA TOKUGAWA, O.B.E., rst Secrry to the Japanese Embassy, "The Eaquake and the Work of Reconruction Japan." (With Cinematograp Illustrats.) LORD ASKWITH, K.C.B., K.C., DL., Chairman of the Council, ill presid

FEBRUARY 13.—H. MAXWELL-LEFROY, M.A., Pfessor of Entomology, Imperial College Science and Technology, "The Preservaon of nber from the Death Watch Beetle." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., will preside.

FEBRUARY 20.—PERCIVAL JAMES BURGESS, A., F.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

FEBRUARY 27.—CHARLES S. MYERS, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

MARCH 5.—MAJOR-GENERAL SIR FABIAN WARE, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman Imperial War Graves Commission, "Building and Decoration of the War Cemeteries."

MARCH 12.—ALAN A. CAMPBELL SWINTON, F.R.S. late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.) SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., will preside.

MARCH 19.—R. L. ROBINSON, Member of the Forestry Commission, "The Forests and Timber Supply of North America." LORD LOVAT, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O will preside.

MARCH 2—NEAL GREEN, "The Fishing Industry and its By-Products."

Dates to be hereafter announced:—

SIR LYNDEN MACASSEY, K.B.E., "London Traffic."

BRIGADIER-GENERAL SIR HENRY MAYBURY, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "Roads."

FRANK HOPE-JONES, M.I.E.E., Vice-Chairman British Horological Institute, "The Free Pendulum."

J. ROBINSON, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MRS. ARTHUR MCGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons at 4.30 o'clock:—

FEBRUARY 15.—SIR RICHARD M. DANE, K.C.I.E., Commissioner, North India Salt Revenue, 1898-1907, and Inspector-General of Excise and Salt for India, 1907-09, "Salt Manufacture in India." THE RT. HON. LORD MESTON, K.C.S.I., LL.D., will preside.

MAY 2.—JOCELYN F. THORPE, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced:—

BHUPENDRA NATH BASU, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons at 4.30 o'clock:—

FEBRUARY 5.—F. W. WALKER, "The Commercial Future of the Backward Races, with Special Reference to Papua." SIR GEORGE R. LE HUNTE, G.C.M.G., will preside.

MARCH 4.—THE HON. T. G. COCHRANE, D.S.O., "Empire Oil: The Progress of Sarawak." THE RT. HON. LORD BEARSTED will preside.

MAY 27.—C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

CANTOR LECTURES.

ERIC KEIGHTLEY RIDEAL, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." Three Lectures.

SYLLABUS.

LECTURE II: JANUARY 28.—Suspension Colloids. Peptisation, protection and precipitation. Colloidal Mill. Electric cataphoresis and endosmose. Peat drying. Colloidal metals, Colloidal fuel, Ore flotation. Smokes, condensation of fumes, powdered fuels. Mists, Insecticides.

LECTURE III: FEBRUARY 4.—Emulsion Colloids. Preparation and Stabilisation. Coal tar disinfectants, Milks, Phase inversion, biological importance, greases, antigens. Soaps. Ionic micellae.

Adsorbing Gels. Silica gels, ferric oxide and alumina, clays, vaseline, rubber and textiles. Membranes, permeability. Equilibria at membranes, application to leather.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

Cobb Lectures.

Monday evenings, at 8 o'clock:—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, January 28..Geographical Society, 135, New Bond Street, W., 8.30 p.m. Mr. S. C. Bullock, "The Tocantins and Araguaya Rivers, Brazil."

Architectural Association, 34, Bedford Square, W.C., 8 p.m. Mr. B. Oliver, "The Case for the Preservation of Old Buildings."

University of London, University College, Gower Street, W.C., 4.15 p.m. Prof. L. M. Brandin, "La Poésie Lyrique Francaise du Moyen Age."

5.15 p.m. Dr. A. S. Parkes, "The Mammalian Sex-Ratio." (Lecture I.).

At the Royal School of Mines, Imperial College, South Kensington, S.W., 5.15 p.m. Prof. H. H. Dixon, "The Transpiration Stream (Botany). (Lecture I.)

At King's College, Strand, W.C., 6 p.m. Mons. R. Nathan, "Le Théâtre d'Idées, Alexandre Dumas Fils." (In French).

5.30 p.m. Dr. O Voladlo "Channels of Modern Czech Literature." (Lecture II.).

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Mr. C. H. Maltby, "Some suggested Amendments to the Assurance Companies Act, 1909."

Scottish Society of Arts, 54, George Street, Edinburgh, 8 p.m. Captain P. P. Eckersley, "The Thermionic Valve and its Application to Broadcasting."

day, January 29..Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. A. Dendy, "What is Heredity?" (Lecture I.).

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, Piccadilly, W., 4.30 p.m.

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. J. Williams, "Book Illustration Previous to Photography."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. H. Campbell, "The Gas Turbine."

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. G. A. Sutherland, "Auditorium Acoustics."

At King's College, Strand, W.C., 5.30 p.m. Sir Bernard Pares, "Russia before Peter the Great to 1801." (Lecture II.).

At the Royal School of Mines, Imperial College, South Kensington, S.W., 5.15 p.m. Prof. G. H. Dixon, "The Transpiration Stream." (Botany). (Lecture II.).

Dyers and Colorists, Society of, Dyers' Hall, Dowgate Hill, E.C., 7 p.m. Dr. A. C. Thaysen, "The Effect of the Action of Micro Organisms on Fibres and Fabrics."

Wednesday, January 30..United Service Institution, Whitehall, S.W., 3 p.m. Major-General Sir J. H. Davidson, "Imperial Defence."

British Decorators, Institute of, Painters Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. W. H. Cantrill, "A Pilgrimage to the Hill Towns of Umbria."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. B. H. Morgan, "The Work of the Imperial Economic Council."

Literature, Royal Society of, 2. Bloomsbury Square, W.C., 5 p.m.

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. C. Davenport, "Illuminated M cripts."

At King's ege, Strand, W 5.30 p.m. Mr. L. F. zman, "Medie Industries and Socie."

At the Lo School of Econc s, Houghton Street, lwych, 5.30 p.m. Dr. A. P. Newton, " Founding of e British Empire."

At the Ro School of Mi Imperial College, Sout ensington, S. 5.15 p.m. Prof. H. H. ixon, "The nspiration Stream." (B y). (Lecture II.)

Hull Chemical nd Engineeri Society, Photographic iety's Rooms, ey Street, Park Street, ll, 7.30 p.m. r. C. H. Hardy, "A R w of the Pres Position of Liquid Fuel

Thursday, January 31.. al Institution, Albemarle Street, W., 5. p.m. Mr. Sickert, "Straws from umberland rket." (Lecture III.)

Antiquaries, Soci of, Burling House, Piccadilly, W., 0 p.m.

Electrical Enginee Institution Victoria Embankment, W., 6 p.m. P . W. M. Thornton, "Som Researches o the Safe Use of Electricit n Coal Min "

Royal Society, Bu gton House, iccadilly, W., 4.30 p.m.

Auctioneers and Est Agents, Inst te of, 34, Russell Square, W.C., 6.30 .m. Mr. H. Beavan, "Va tions."

Economics and Po cal Science London School of, Hou n Street, ldwych, W.C., 5 p.m. Sir bert L. Sm h, "The Economic Laws Art Pro ction." (Lecture III.)

University of Lond University College, Gower Street, W., 5.30 p . Prof. E. G. Gardner, " ano Bocca , Critic and Humorist."

5.15 p.m. Prof. J. G. de Mon orency, "Comparative Custo y Law of E ope and Asia." (Lecture II.

8 p.m. Prof. H. Butler, " Roman Private Life." (Lect II.)

At King's College, St d, W.C., 30 p.m. Prince D. S. Mirsky, " e History Russian Literature." (Lecture II.)

At the London School o edicine fo Women, Hunter Street, W.C., p.m. Pr W. C. Cullis, "Respiratory xchanges (Lecture II.)

Chemical Industry, So ty of idland Sections), University ildings, dmund Street, Birmingham, 7. p.m. M . H. T. Tizard, "Some Spe l Probl ms in Volumetric Analysis."

Friday, February 1..Royal Institution, Albemarle Street, W., 9 p.m. of Sir William Bragg, "Recent Resea on Crystalline Structure."

Philological Society, U ersity College, Gower Street, W.C., p.m. Prof. A. Mawer, "English Place N e Society."

Geologists Association, U ersity College, Gower Street, W.C., 7.30 m.

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., p.m. (Informal Meeting). Mr. H. H. hnson, "The Possibility of Main Line Ra ay Electrification in Great Britain."

(Yorkshire Branch), Philo ophical Hall, Park Row, Leeds, 7.30 p.m. r. L. Pendred, "The Production of Technic Newspapers."

Photographic Society, 35, ssell Square, W.C., 7 p.m. (Pictorial Gro). Mr. F. C. Tilney, "An Impromptu aturalism in Photography."

University of London, University College, Gower Street, W.C., 5 p.m. Prof. J. Robertson, "The Influence of own Planning and Housing in Public Health." (Lecture II).

5.15 p.m. Mr. H. Higgs, "P otection and Free Trade."

At King's College, Strand, W.C., 5 p.m. Dr. W. D. Lang, "Some Paeontological Evidence with regard to Evolution." (Lecture I.)

5.30 p.m. Prof. R. W. Se on-Watson, "The Rise of Nationality in the Balkans." (Lecture II.)

Saturday, February 2..Royal Institution, Albemarle Street, W., 3 p.m. Mr. W. Wallace, "Influence upon Composition of Improvements in Musical Instruments."

Journal of the Royal Society of Arts.

No. 3,715 VOL. LXXII.

FRIDAY, FEBRUARY 1, 1924.

25 FEB.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2).

NOTICES.

◆

NEXT WEEK.

MONDAY, FEBRUARY 4th, at 8 p.m. (Cantor Lecture). ERIC KEIGHTLEY RIDEAL, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." (Lecture III.)

TUESDAY, FEBRUARY 5th, at 4.30 p.m. (Dominions and Colonies Section). F. W. WALKER, "The Commercial Future of the Backward Races, with Special Reference to Papua." SIR GEORGE R. LE HUNTE, G.C.M.G., will preside.

WEDNESDAY, FEBRUARY 6th, at 8 p.m. (Ordinary Meeting). IYEMASA TOKUGAWA, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." (The paper will be illustrated with cinematograph views.) LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

SEVENTH ORDINARY MEETING.

WEDNESDAY, JANUARY 23rd, 1924; MR. GEORGE E. BROWN, F.I.C., Editor of the *British Journal of Photography*, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Bailey, Charles Henry, Chepstow, Mon.
Chamberlain, Clark W., A.B., Ph.D., Granville, Ohio, U.S.A.
Charawanamuttu, V. Edward, A.C.P., Kotahena, Colombo, Ceylon.
Cutner, Mrs. Frances Maud Mayfield, London.
Davis, Cecil, London.
Edwards, Kenneth C., Chester.
Evans, Samuel, Johannesburg, S. Africa.
Fuge, Captain William Valentine Greatraks, Cairo, Egypt.
Graham, Archibald, Oxford.
Gray, Arthur Wellington, Ph.D., Delaware, U.S.A.
Gray, Major-General William du Gard, C.B., J.P., Dulverton, Somerset.
Hooker, Dr. Samuel Cox, Brooklyn, New York, U.S.A.
Jones, Arthur Cadbury, London.
Khadir Meera Sahib, S.K.I., Salem, India.
Kimbell, Alfred Edward, London.
Klein, Millard A., Ph.D., Stockton, California, U.S.A.
McGregor, Dr. Robert, Michigan, U.S.A.
McLaughlin, Professor George D., Cincinnati, Ohio, U.S.A.
Matthews, William Cooper, Stafford.
Morley, Henry Thomas, Reading.
Morrison, Francis, B.Sc., London.
Morse, Charles, K.C., D.C.L., Ottawa, Canada.
Plummer, Professor Henry Stanley, M.D., Minnesota, U.S.A.
Pullen, Hugh C. G., Rio de Janeiro, S. America.
Ramsay, Dr. William Miller, Nausori, Fiji.
Rose, Joseph William, Bath.
Rose, Mrs. Ruth Starr, Maryland, U.S.A.
Rosenberg, Charles Conrad Constantine, M.D., Oregon, U.S.A.
Sahni, D. C., M.A., Patiala, India.
Spencer, Walter T., London.
Tatham, Francis John, London.
Townson, Rev. C. H., M.A., Warminster.
Ward, Sir Thomas Robert John, C.I.E., M.V.O., London.

The following candidates were duly elected Fellows of the Society:—

Clark, John Murray, LL.D., K.C., Toronto, Ontario, Canada.
Cullen, Jos. F., Salt Lake City, Utah, U.S.A.
Goode, Clarence S., M.Inst.R.E., Hinckley.
Hibberd, Reginald James, M.Inst.R.E., Haslemere, Surrey.
Keith, Charles, Kansas City, U.S.A.
Ledigard, Edgar M., Salt Lake City, Utah, U.S.A.
Life, Professor Frank M., Tucson, Arizona, U.S.A.
Manekshaw, F. H., London.
Mitra, S. B., London.
Rayakar, B. V., Bombay, India.
Sethna, F. M., Bombay, India.

A paper on "Cinematography in Natural Colours—further Developments," was read by MR. G. ALBERT SMITH.

The paper, which was fully illustrated with scenes from H.R.H. The Prince of Wales's Tour in India, will be published in a subsequent number of the *Journal*.

CANTOR LECTURE.

On MONDAY, JANUARY 28th, 1924, DR. ERIC K. RIDEAL, M.B.E., B.A., D.Sc., F.I.C., of the Chemical Laboratory, The University, Cambridge, delivered the second lecture of his course on "Colloid Chemistry."

The lectures will be published in the *Journal* during the summer recess.

REPRINT OF CANTOR LECTURES.

The Cantor Lectures on "Precise Length Measurements," by Mr. J. E. SEARS, Jun., C.B.E., M.A., M.I.Mech.E., A.M.Inst.C.E. have been reprinted from the *Journal* and the pamphlet (price 4*s.*) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.2.

A full list of the lectures, which have been reprinted and are still on sale, can also be obtained on application.

BINDING COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their annual volumes of the *Journal*, cloth covers can be supplied, post free, for 2*s.* each, on application to the Secretary.

SCHEME FOR THE IMPROVEMENT OF INDUSTRIAL DESIGNS.

A short article describing the Scheme for the Improvement of Industrial Designs, which the Society is inaugurating, appeared in the *Journal* of October 26th, 1923. This outlined the objects of the Scheme, and gave the names of those serving on the various Committees, and the first list of subscriptions to the fund for providing scholarships and prizes. Since that date the following additional subscriptions have been received:—

SECOND LIST OF SUBSCRIPTIONS TO THE FUND FOR PROVIDING PRIZES AND SCHOLARSHIPS.

Amount previously acknowledged	£589	5	0
The Federation of Calico Printers ..	50	0	0
Messrs. Lever Bros., Ltd., ...	50	0	0
The British Flint Glass Manufacturers' Association	30	0	0
Messrs. G. P. & J. Baker, Ltd. ..	20	0	0
Messrs. Brintons, Ltd.	10	10	0
Carpet Trades, Ltd.	10	10	0
Messrs. John Dickinson & Co., Ltd. ..	10	10	0
The Haberdashers' Company	10	10	0
Messrs. Hampton & Sons, Ltd... ..	10	10	0
The Weavers' Company	10	10	0
E. Kahn, Esq.	10	0	0
Messrs. Riddick, Stuttart, Ltd. ..	10	0	0
George Barber, Esq.	5	5	0
Mrs. E. Graydon-Bradley	5	5	0
Messrs. Heal & Son, Ltd.	5	5	0
William Jardine, Esq.	5	5	0
Messrs. Keeble (1914), Ltd.	5	5	0
London Cabinet and Upholstering Trades Federation	5	5	0
Messrs. Mander Bros.	5	5	0
The Medici Society, Ltd.	5	5	0
Thomas Muddiman, Esq.	5	5	0

The first Annual Competition of Industrial Designs will be held in June next at the Victoria and Albert Museum, and particulars can be obtained on application to the Secretary of the Royal Society of Arts. Over £1,000 will be offered in Travelling Scholarships and Money Prizes in the various sections, and the Society's Diploma will be conferred on any candidate whose work reaches a very high standard of artistic ability and also shows practical knowledge of the materials and processes of his trade.

A number of selected designs will be exhibited at the Victoria and Albert Museums, and subsequently at suitable centres in the provinces. In this way they will be brought immediately to the notice of those manufacturers who are likely to be specially interested in them.

The Council hope to place the Scheme on a permanent basis and to offer annually travelling scholarships and prizes. In order to secure this object a very substantial capital sum will be required. They therefore appeal to all those who not only are interested in the artistic industries of the country, but are concerned for the general improvement of British trade to assist them in promoting the Scheme. Contributions to the Fund should be addressed to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.2.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

FRIDAY, JANUARY 4TH, 1924.

GENERAL SIR EDMUND BARROW, G.C.B., G.C.S.I., Member of the Council of India, in the Chair.

THE CHAIRMAN said he had only one qualification for presiding on such an occasion. It would be remembered that Mr. Birrell frequently prided himself on the fact that he was born in a library. He (the Chairman) could boast that he had been born in an Indian arsenal, and, therefore, had some connexion with the Ordnance Department. His father, an Artillery officer, at the time he (the Chairman) was born was in charge of the Secunderabad Ordnance Depot.

The lecturer, General Young, had had over 30 years' experience of the Indian Ordnance Department, having served in most of the Indian factories. In 1914, just after the War commenced, he became Deputy-Director of Ordnance in India, and in 1917 Director of Ordnance. He thus spoke with considerable knowledge both of the Indian Ordnance in pre-war days and of the Indian Ordnance during the Great War. For his work as Deputy-Director General Young gained the Companionship of the Order of the Indian Empire, and later obtained the C.B.E.

The paper read was :—

THE INDIAN ORDNANCE FACTORIES AND INDIAN INDUSTRIES.

By BRIGADIER-GENERAL H. A. YOUNG, C.I.E., C.B.E., (R.A., retired).

Director of Ordnance Factories, India, from 1917 to 1921.

The production and supply of military equipment is a by-way of history but little explored by the historian. The earliest armies obtained their weapons from the nearest forest or beach and nobody thought it necessary to describe the forest or the beach, and the fashion thus set has been followed down to quite recent times. The last great war has made us realise, however, that, while an army may march on its stomach, a nation fights with its factories. Before the invention of gunpowder the fighting man, if he could not equip himself, was able to obtain his needs from local craftsmen. The provision of firearms and powder required special industries which could be carried on only by numbers of workers acting together in organised workshops. Originally these workshops were privately owned and in England it was not till 1716 that the manufacture of cannon was established in a Royal Foundry at Woolwich, and not till 1787, when mills at Waltham were purchased, that gunpowder was produced in quantity in a State owned factory.

The Ordnance Factories in India have a long and interesting history, distinctly creditable to the officers who have managed them ; but this history has never been written and less is known to-day of the sources of supply of Indian Army equipment than was known in the first half of last century, when the officers of the Arsenals and Factories came from the Presidency Artilleries and returned to regimental duty for service and on promotion to Lieutenant-Colonel. Rare indeed, in my experience, have been visits from officers unconnected with the Department to any Ordnance establishment. A Commander-in-Chief was once allowed half an hour for a visit to the Cordite Factory and was amazed to find that he could not enter any building nor view manufacture in the allotted time.

The East India Company in its early days was interested in military equipment mainly as saleable goods. Despatches of muskets, shot, powder and guns for sale are recorded from 1600 onwards. In 1658, 15 iron guns, 2 mortars and 800 shell were consigned to Madras to be sold "to our most profitt," it being believed that the wars in India would cause a great demand for such things.

In 1626 the Company attempted to establish powder works in England and set up mills near Windsor ; but the King ordered their removal, as they disturbed the royal deer. Mills were then rented at Chilworth ; but Evelyn, who had the monopoly of powder making, obtained an interdict. When this was removed, the Company's Powder Maker, a survivor of the Amboyna Massacre, died, and finally there was trouble over the rent, so in 1636 they assigned the lease and abandoned the idea of making powder in England. This decision must also have been due to a realisation of the possibilities of manufacture in India, where all materials were easily obtainable. Though neither gunpowder nor firearms were invented in India, and their first recorded use was at the Battle of Panipat in 1526, their manufacture had been quickly established in many of the Indian kingdoms.

The first manufactories established by the Company in India were Powder Mills, though the exact date is uncertain. In 1660 a ship was sent from Surat to Calicut to "obtain a supply of gunpowder, which was very dear at Surat, as there was only one maker there." In 1670, however, the Council ordered the Factors at Karwar to buy saltpetre for powder manufacture at Bombay, and seven years later recommended a Surat powder maker who was prepared to make powder at Bombay at a specially cheap rate. Bombay seems to have accepted the offer and a powder mill was built not far from the Castle. Madras must have had a powder mill in 1672, as in that year the Chief at Masulipatam was ordered to send teak timber to Madras for the Powder Mills, which were located in old Black Town.

These early gunpowder factories were not substantially built works making powder of any quality; even up to the end of the 18th century powder was made by the most primitive methods, in the cheapest structures and with little regard to the danger of the operations. In the first powder works at Bombay the ingredients were beaten in wood mortars by women and boys, who were pressed for the work, and even in 1794 powder was made by the Agent in Bengal by foot mills in mat huts and sifted in leather sieves. Explosions were frequent, often causing great loss of life, for, in addition to the risks attendant on the use of primitive appliances, there was often extraordinary carelessness. For example, at Bombay in 1677, some 35 barrels of powder were spread out to dry on a bastion, when a corporal filled an old bandolier with wildfire, intending to tie it to a dog's tail, but not finding the dog, threw the bandolier towards one of the houses. The wind being very strong the bandolier blew on the bastion, fired the powder, which killed a sentry and 8 coolies, blew open magazine and other doors, shook the town and damaged the bastion. They held a Council of War on the corporal, cashiered him and made him run the gauntlet three times as an example to all. The location of the mills was constantly changed as explosion destroyed them or they became surrounded by houses. At Madras after the first one there were three in succession on different parts of the Island, one of which was destroyed by the French in 1746. Then powder came from Fort St. David till, in 1753, mills were erected in the Egmore Redoubt, materials from a church in Fort St. George being utilised. Six years later the French destroyed these works and temporary sheds were used till they blew up, killing many people. The next site was in new Black Town, on the ground now occupied by the Government Press, and when these mills were ruined by explosion, works were established in 1802 at Perambur, which continued till powder manufacture ceased in 1887. At Bombay the second site was on Old Woman's Island, now called Colaba, as in 1731 the original works were pronounced crazy and dangerous. Forty pestles worked by buffaloes were provided; but if buffaloes proved unsatisfactory, a windmill was to be erected. These works were soon abandoned as they were out of the way for the workers, there was no fresh water and no store houses, and other mills were set up on a site near the first. The powder made was said to be superior to Europe powder, though the Court thought it should have been cheaper, but at this time English powder was most indifferent and Fortescue states that as late as 1779 Admiral Barrington was complaining bitterly about its quality. These works having extended too near the Fort they were removed to Mazagon in 1768, where they remained till 1864. The final move was to Kirkee, where modern works were completed in 1870, and continued working till 1899. This move was a profitable one, as the site fetched 40 lakhs while the new works cost only 16½ lakhs.

It does not appear that Bengal possessed any Government Powder works before 1756, though it is stated that prior to this year Government had spent much money on manufacturing powder near Baugh Bazaar, but with little success. In 1754 proposals for "contracting with the Company for gunpowder" were accepted from Lieutenant-Colonel Scott, who was Engineer General of all the Company's settlements in the East Indies. He built a powder mill at Perrin's Garden in Baugh Bazaar and on his death, in May, 1754, it was taken over by Captain John Buchanan, who had married a lady said to have been Scott's niece. Buchanan died in the Black Hole and his widow became the first wife of Warren Hastings. Before the siege of Calcutta, however, the powder works had been purchased for the Company for Rs.4,000, Buchanan to receive a gratuity for managing them, and the Council reporting to the Court that they had taken the provision of gunpowder into their own hands. The Court, in approving this action, referred to the importance of the matter and left to the Council to have it made of the best quality and in cheapest manner by contract or otherwise. The Court were never slow in urging economy and in 1759 they informed Bengal that, to save needless expense in powder, they had made new regulations permitting in certain cases ships to salute by cheering. Baugh Bazaar was obviously unsuitable for powder works and for a short time the works were at Akra, between Budge Budge and Kidderpore and Warren Hastings had a farewell dinner with a number of friends at these works on the day he left Calcutta in 1785.

The establishment of powder manufacture in Bengal on a proper scale was due to a remarkable man. Mr. John Farquhar went out to Bombay as a cadet; but having become unfit for active service owing to wounds, he went to Bengal as a free merchant and took up chemistry as a hobby. Lord Cornwallis employed him to investigate the powder works, then made him superintendent and finally sole contractor. The location of the works down the river was considered dangerous by the military authorities and at Farquhar's suggestion the old Ostend Company's settlement at Bankee Bazaar was acquired and he was authorised to erect new works there. These works at Ishapore, as the place came to be called, were completed about 1790 and worked till 1903. Farquhar was unique among Ordnance Factory Superintendents, for he took home with him, when he retired in 1814, half a million pounds and walked from Tilbury to Leadenhall Street to save cab fare.

For close on 30 years Bengal had powder works also at Poppa Mhow near Allahabad, where for a time war rockets were made. It was closed in 1829 by Lord William Bentinck as one of his economies. The three powder works at Kirkee, Ishapore and Perambur are now represented by the Cordite Factory at Auruvankadu, which commenced manufacture in 1904, and the various dangerous operations there have been conducted with extraordinary freedom from serious accidents.

India has always been dependent to a large extent on England for ordnance. Gun making was attempted at Madras in 1709, when a German was entertained in the Gunner's crew as he was said "to perfectly well understand casting of guns and mortars of any size as also how to play 'em." Less than three years later he was pronounced "a person of no judgment," as guns he made split when proved, and he was ordered to be discharged or reduced to gunner's mate. In 1771 a brass foundry was added to the Arsenal of Fort William and ten years later it cast two 12prs. and ten 6prs. for the ship Betsey, going to China with opium. This foundry became a separate charge in 1822, and in spite of the desire of the Court to abolish it, it continued till 1830, when it was removed to Cossipore and re-equipped. From that year it grew till in 1914 it had spread into two great factories, one at Cossipore and one at Ishapore, making not only modern guns and howitzers but projectiles, fuzes, cartridge cases and many other military stores.

It is curious that the Company did not establish gun manufacture earlier and on a more adequate scale, as the manufacture of brass ordnance, even of large calibre, was well established in many parts of India. A gun 4ft. 8 ins. diameter at the muzzle with a bore of 2ft. 4ins. was cast in Ahmednagar as early as 1549. One Richard Bell tells a quaint story of casting guns for Aurangzeb, the guns taking 160 lbs. of powder and a shell of 450 lbs. When he proved the guns he used an elephant as a target, with fatal results to the elephant and much annoyance to the Emperor. There is a letter from the Court dated in 1763 which may explain their neglect of gun making. It says:—"Your indent for brass and iron guns and ordnance stores is so great that it is a further confirmation of our before-mentioned remarks of last season upon the inattention in framing your indents. We cannot therefore by no means think of complying with it fully, more especially when we consider what large quantities have been taken from the French in the different parts of India." In those simple days a successful army could re-equip itself from the enemy, and some enemies in India were far better equipped than the British. In Seringapatam, when we took it in 1799, there were 444 brass and 478 iron pieces of ordnance, most of the brass and a few of the iron having been cast in Tippoo's own foundry. The fortress had 11 large powder magazines, containing over half a million pounds of powder, 11 armouries with workshops, 2 foundries, 3 gun workshops and 4 great arsenals.

Muskets and rifles have always been imported; but in 1905 a rifle factory was established at Ishapore on part of the site of the old powder works. It had many difficulties to overcome, especially in the training of workmen in the extremely accurate work required in the modern rifle, and it had not reached full production when the Great War broke out.

Ordnance vehicles were made in the country from the earliest times, but no factories under Government control were established till the beginning of the 19th century. Formerly, supplies came mainly from contractors, most of the iron work being imported; and one of the reasons for the defenceless state of Calcutta in 1756 was the lack of carriages for 50 guns newly received from home, the iron work not having arrived though demanded in 1754. A writer, referring to the latter part of the 18th century, says:—"Carriages, ammunition and stores generally were of exceedingly inferior quality, supplied by contractors, who having interest to obtain the contracts, had also sufficient influence to force their wretched produce into the service and to cover themselves from loss or exposure by getting all power of choice or rejection taken from the hands of the Artillery officers." When the Board of Ordnance was instituted in 1775, it placed the arrangements for equipment in the hands of the Commissary General and the Military Storekeeper, who were either themselves contractors or were connected with the contractors. William Hickey in his memoirs says that the position of Military Storekeeper was, in 1783, the most lucrative one in the Company's service. He mentions a Chief Engineer who left over half a million pounds and another gentleman who made £60,000 from a contract at Madras for some batteries.

Gun carriage manufactories were established at Calcutta in 1800, at Seringapatam in 1802 and at Bombay in 1810. The Bengal factory was first at Kidderpore, then both there and at Cossipore. In 1814 another factory was established at Allahabad but was moved to Fatehgarh two years later, and in 1829 the Calcutta factory was also moved to Fatehgarh, which became the sole gun carriage manufactory for the Bengal Army. Even at the time of the Sepoy Mutiny neither this factory nor the fort within which it was situated can have been very impressive. The fort was very dilapidated and the factory was thus described by a writer in 1857:—"The Agency yard is merely an enclosure surrounded by mud walls on three sides, abutting on the river on the fourth. Within these walls is a bungalow for the Agent and large godowns for the reception of muster guns, carriages, ammunition, etc." When the rebels besieged the fort there was no armament other than the muster or pattern guns and the scanty ammunition was supplemented by hammer heads, bolts and nuts. The factory was little injured by the rebels, who attempted to utilise its resources but with small success.

The establishment of a gun carriage factory for the Madras Army was due to the failure of carriages from contract during the operations in Hyderabad, while its location at Seringapatam was the result of the recommendation of Sir Arthur Wellesley. The first Agent was Captain Scott, of the Madras Artillery, who had been called to Seringapatam as Commissary of Stores by Wellesley, owing to serious scandals in the store department. Wellesley wrote in 1801:—"You cannot conceive what a scene of villany has come out." The advantages of Seringapatam did not last, and in 1831 the factory was located in Madras in the Collector's Cutchery, which was formerly the Naval Hospital.

The Bombay factory was located first near the Bazaar Gate, on the site now occupied by St. George's Hospital; but in 1819 the Court approved of its removal to the barracks, lately occupied by the artillery, on Old Woman's Island. In 1841 the Cooperage work of the Military and Marine Departments was transferred to the factory from the Commissariat, and the monopoly of the native contractors was broken down. In 1868 the manufacture of wheels, which was unsatisfactory in the damp climate of Bombay, was transferred to the Poona

Arsenal, and five years later all wood work was concentrated in a branch of the factory at Poona.

Many proposals were made from time to time for the removal of the gun carriage factories to more suitable sites and for their concentration. As far back as 1864 the unsuitability of Bombay was urged, and in 1875 a special Ordnance Commission recommended two factories at Allahabad and Madras. It was not till 1901, however, that Government decided to concentrate all ordnance vehicle work at a central factory at Jubbulpore, and work commenced there in 1904, the existing ones being gradually closed down.

The history of the manufacture of harness, saddlery and accoutrements is somewhat obscure. At first all supplies were imported ; but gradually local provision by contract grew up, though importation and to some extent manufacture in Arsenal workshops supplemented this. In 1771 the stock of the Grand Arsenal at Patna included 1,206 country-made sword belts against 2,206 from England. Tanneries owned or managed by Europeans existed in the 18th century, while Commissariat tanneries were fairly common early in the 19th. Madras stated in 1832 that boots and leather appointments were being made of superior quality and at reduced rates at the Commissariat tannery at Hunsur and in 1840 reported that buff leather for accoutrements was also being made there, though only half the annual requirements could be supplied. There is little doubt, however, that the supply of leather was not satisfactory. Bombay informed the Court in 1843 that harness and saddlery supplied by contract was very inferior though no worse than that made in Bengal or Madras, and that Europe harness was much more efficient and economical. A writer in 1848 in an article on the Bengal Artillery stated that "the worst part of the equipment is harness and saddlery, in which considerable improvement is required which can never be obtained till all is supplied from England. Country harness costs nearly as much, lasts half as long and is in every respect inferior. It is understood that the only reason is that the Court desire to improve and encourage Indian manufactures." The truth is that indigenous methods of tanning could not, and do not now, produce good leather.

The history of the Government Harness and Saddlery Factory commences in 1860, when Lieutenant John Stewart, of the Bengal Artillery, was a Deputy Commissary of Ordnance at Cawnpore, and recognised the importance of the place as a centre for leather work, as well as the urgent necessity for improvement in methods. At his suggestion an experimental harness depot was started and the system of tanning in pits adopted in place of the native method of tanning in bags. Tanning was done by contractors, but as they failed to make proper pits or to do the work thoroughly, two experts were obtained from home and manufacture commenced in the depot in 1862. It was not till 1873, however, that the factory really became self-contained and able to turn out complete articles of equipment from the raw materials and in that year it obtained a medal and diploma at the Vienna Exhibition. Stewart remained in charge till 1888, a record for service in one appointment, and his memory is perpetuated by a mounted figure on a temple outside the factory walls. This factory has not always been the sole source of supply, as for many years leather articles were made up in the Bombay Arsenal from leather obtained by contract. The Commission of 1875 recommended that the Cawnpore factory should be extended to meet all requirements ; but from 1897 to 1909 harness and saddlery workshops were established in the old powder works at Perambur, leather being obtained from Bombay by contract. The existence of the Cawnpore factory has been threatened more than once, it being thought that the private leather working factories rendered unnecessary any Government establishment. It was most fortunate that the idea had not borne fruit when the War came, as the European managed private factories had more than they could do to cope with the demand for boots, while the ordinary Indian tannery could not produce good leather. The products of this factory are equal in every respect, except possibly appearance, to those produced in Europe.

The history of the ammunition factories is a short one, though the manufacture of ammunition dates from 1748, when the Court sanctioned the raising of a regular company of artillery in each Presidency and sent out a Captain-Lieutenant for each company as Director of the Laboratory. The Court directed that this officer was to have charge of all necessary stores and was "to make and to instruct in making all military fireworks." The laboratory thus established was the original ammunition factory. The Court desired this institution to be a mystery, as they ordered that "no Indian, black or person of mixed breed, nor any Roman Catholic of what nation soever, shall, on any pretence, be admitted to set foot in the laboratory, or any of the military magazines, either out of curiosity or to be employed in them, or to come near them, so as to see what is doing or contained therein." It soon became impossible to depend on the Company laboratories and in 1790 Commissaries and Deputy Commissaries of Ordnance were directed to perform the business of making up ammunition and all laboratory work under the direction of the Commanding Officers of Artillery.

The change from Arsenal Laboratory to Ammunition Factory was a gradual one and commenced with the establishment of percussion cap factories. One started in the Mazagon Powder Works in 1844 and another at Dum Dum about the same time. Bullets for the Minie rifle were also made in small factories, one being at St. Thomas's Mount from 1858 and another at Bombay, in the Gun Carriage factory, which included also plant for cutting fuzes and tubes. The Cossipore factory also made bullets. The ammunition factory at Dum Dum really dates from 1858, when Captain Symo, of the Bengal Artillery, was placed in charge of the Enfield Cartridge and Percussion Cap Factory; but it was not till 10 years later that the Secretary of State sanctioned the establishment for the new Small Arms Ammunition Factories. The two factories at Dum Dum and Kirkee, the latter completed in 1872, became eventually gun as well as small arm ammunition factories, and in 1901 buildings for the lyddite filling of shell were added to the Kirkee establishment. Unfortunately these factories were still making Mark VI rifle ammunition at the opening of the War, and it was not till some years later that sanction was given to the few alterations necessary to enable the latest pattern to be made. This matter of ammunition had grave results in Mesopotamia, where British-equipped divisions were fighting side by side with those from India, having different ammunition, different methods of carrying ammunition and rifles sighted differently. It is to be hoped that the lesson has been well learnt and that never again will vital military equipment vary in different parts of the Empire.

Now, a few words regarding the personnel. Up to the close of the 18th century equipment was mainly supplied by contract. Though works were the property of Government as in the case of the powder mills, though workshops were provided as in the case of carriage manufacture, the person who supervised the work was remunerated from the price fixed for the article. When powder was made by Colonel Scott or by Captain Buchanan, both officers drawing pay from the Company, the profits of manufacture went to them. Mr. John Farquhar, when he was superintendent at Ishapore, received Rs. 5 for each barrel made, and when he became contractor he was given Rs. 32 per barrel. Dr. Helenus Scott, of the Bombay Medical Service, who was agent for gunpowder in Bombay from 1796, was paid for the powder produced and had also the contract for spirits. It was not till 1813 that the Court decided that superintendents of factories should be army officers, preference being given to the Artillery. A few years later it was ordered that no officer in such an appointment was to derive any profit from it other than the authorised pay and allowances, which, I may mention, were higher than in recent times. These appointments were bestowed on fairly senior officers as a rule, with claims to reward, either from distinguished service or sometimes from relationship with high authority. Many distinguished officers appear in the lists, including Augustus Abbott, who commanded the artillery of the 'illustrious garrison' of Jellalabad, Vincent Eyre, who relieved Arrah, Archdale Wilson, who commanded at the siege of Delhi. Many officers were thanked and rewarded for their services in improving or cheapening manufacture, though there were cases when the Court were moved to ask what enquiry had been made into the qualifications of the officer before appointment.

It is obvious that any officer, whose experience has been purely military, must have much to learn when appointed direct to the charge of a manufacturing establishment. Yet it was not till nearly the end of the 19th century that a Director General of Ordnance was found far-sighted and strong enough to insist that there must be a graded service in which officers would have to qualify themselves for positions of responsibility. To the late Major-General Alexander Walker must be given the chief credit for the efficiency of the Ordnance

Department during the past 30 years. Unfortunately the principles which General Walker followed have since been departed from, and this is perhaps one reason why it is now difficult to obtain officers for the factories.

It has been urged that the Artillery officer is not the best possible factory superintendent and that the present large manufacturing establishments would be more efficient if placed under civilian engineers. A good deal can be said on both sides, and, no doubt, the best engineer would be better than even the picked artillery officer; but no salary likely to be offered by India would attract the best civilians. Many manufacturing companies in this country are controlled by men who have no engineering qualifications, and it is not always best to have purely technical knowledge at the top. The Ordnance Factory Superintendent needs most knowledge of Army requirements and a gift for management. The present eight great Ordnance Factories in India are no unworthy monument to the devoted labours, extending over a century, of the Artillery officer. It is essential, however, if the best type of officer is to be obtained, that the pay be increased and prospects of advancement assured. It would be of advantage to the home ordnance factories as well as to the Indian factories, if there was an interchange of officers and, if possible, of technical foremen also. While the home staff is far more modern in its ideas and methods and is in close touch with industrial progress, it lacks intimate knowledge of the severity of service imposed by climate and other conditions abroad on military equipment.

From quite early days technical men were obtained from England as foremen. In 1753 the Court sent to Bombay a man skilled in burning charcoal to serve on the powder works at £60 a year. When the Gun Carriage Agency was established in Bombay the Court were asked to send out 3 foremen—carpenter, blacksmith and wheelwright. In 1813 a Mr. John Braddock, son of the Master Refiner at Waltham Abbey, was sent to Madras, "to practise and teach the art of making gunpowder." Early in the century the Madras Powder Works had a Frenchman as foundry foreman and he was sent to Calcutta to assist in the casting of cylinders for the Ishapore Works. Supervision was, however, mainly in the hands of Europeans drawn from the Army and employed as overseers, being either warrant officers of the Ordnance Department or soldier mechanics. At the Gun Carriage Factory, Fatehgarh, in 1895, there were 2 civilian foremen, 5 or 6 soldier mechanics and 8 or 9 warrant officers; there were no Indians above the grade of mistry, nor were there any qualified by education or training for any higher post. There was in 1864 a Parsee Head Powder Maker at Bombay on Rs. 280 per month, but he was exceptional, as he had been to England and had acquired knowledge of Waltham Abbey methods.

There has been little attempt to train the Indian for posts of responsibility in the Ordnance factories. There were more schools attached to the factories in the middle of last century than were in existence at its end; but these schools did not pretend to fit lads for supervisory posts. There was a very sound institution started at Madras in 1818; this was the Corps of Carnatic Ordnance Artificers, in which young Eurasians were educated, taught trades and given a chance of rising to positions of minor responsibility. The Corps was allowed to die out, unfortunately, and had practically disappeared by the end of the century. Technical supervision is now carried on almost entirely by civilians recruited from England, warrant and non-commissioned officers of the Ordnance Department being employed for store duties.

In 1885 there were 10 Ordnance Factories, 3 Gunpowder at Madras, Kirkee and Ishapore; 3 Gun Carriage at Madras, Bombay with branch at Poona, and Fatehgarh; 2 Ammunition at Kirkee and Dum Dum; 1 Gun and Shell at Cossipore; 1 Harness and Saddlery at Cawnpore. In 1914 there were 7 only:—1 Cordite at Auruvankadu; 1 Gun Carriage at Jubbulpore; 2 Ammunition at Kirkee and Dum Dum; 1 Gun and Shell at Cossipore with branch at Ishapore, now a separate factory known as the Steel and Metal Factory; 1 Harness and Saddlery at Cawnpore; 1 Rifle at Ishapore. In 1914 these factories employed about 13,000 men and the value of a year's output was approximately 240 lakhs of rupees. At the Armistice the workers numbered close on 39,000, and the value of out-turn was over 880 lakhs. Speaking generally they made complete, from raw materials, field and mountain guns and howitzers, with their carriages and other vehicles, and most of their equipment. Gun and small arm ammunition, rifles, bayonets, transport vehicles, harness, saddlery and accoutrements were also completely made. In addition steel and other metals were melted and rolled for various purposes and the cordite factory made gun-cotton for the Engineer services.

The factories were not prepared for a World War. They were supposed to be capable of maintaining supplies for any frontier war; but Lord Kitchener's plans had not been fully carried out and the manufacturing capacity required to maintain the largest army which India could place in the field had not been worked out. No plans existed for the expansion of the factories and their maximum capacity was not known. India, moreover, had ceased to be in the forefront of military progress and much of its equipment was of patterns discarded by the home army, with the result that the plant of its factories was not adapted for the manufacture of many articles of modern equipment.

For some time the factories worked only the normal 48 hours per week and no adequate steps were taken to expand either in personnel or in plant. Sanction was eventually obtained to the employment of tradesmen from territorial units and later of men from civil life; but the latter were few and the former new to Indian conditions and were rarely technical experts. Even then proper night shifts were impossible, as many factories had no adequate lighting and there was a scarcity of workmen. Unfortunately, civilian industry was not controlled, and continued to use material and labour on work of no military value.

Demands for many new stores poured in from the forces overseas, and it then became apparent how dependent on other countries India was for much of the material used in the manufacture of military equipment. Much of the raw material was in India, but it had either not been exploited or required treatment which could not be given in the country. Moreover, special plant and skilled supervision was often needed which were not available. India could not make, for example, machine guns, bombs, grenades, pistols, trench mortars, high explosives nor the detonating fuze. Acetone, glycerine, sulphur and sodium nitrate all required for explosive manufacture, were imported. India did not even manufacture sufficient leather of good quality and supplies had to be obtained from Australia, though all the necessary materials for leather manufacture are among India's chief exports.

India can point with justifiable pride to what it did in the Great War, but it is possible that future historians may comment on what it might have done had a longer and a wider view been taken and its great resources been exploited from the very beginning. The factories which should have devoted the whole of their none too plentiful labour, material and plant to the production of stores for the forces overseas, were making cartridges for saluting and time guns, special equipment for body-guards and maintaining a host of obsolete guns and other equipment, while a fear of local trouble locked up much valuable material and stock. Some years of war passed before India had shaken off some of its normal administrative inertia.

In 1917 the home authorities sent out a commission, headed by Sir Frederick Black, to consider what could be done to obtain a far larger output of gun ammunition. As a result it was decided to erect new shops complete with plant to produce about three times the existing output, the ammunition to be of the latest patterns. A considerable staff was sent out and buildings erected at Cossipore, Ishapore, Dum Dum and Kirkee; but it was obvious that the difficulties had been underestimated and that the scheme as worked out in England was on too huge a scale for completion within the time allowed. The scheme was managed throughout by the representatives of the Ministry of Munitions; but there was no production and the shops were not completed by 1920. A scheme was prepared in India which would have more than doubled the existing output in a few months at a comparatively small cost, but it did not appeal to the imagination and was turned down.

Towards the end of last century the administration of the factories was removed from the various Inspectors-General of Ordnance and concentrated in the hands of the Director-General. In 1906 a separate office for the purpose was formed under an officer now called the Director of Ordnance Factories; but during 1918 and 1919 this officer ceased to be under the Director-General and was under the Indian Munitions Board, in which Sir George Buchanan was the Member directly concerned. Now the grouping of all the factories under an officer whose whole time could be devoted to their control was an obvious advantage, but there was one grave defect, it placed one more office between the factories and the Government of India, and this was the more serious as little decentralisation was attempted. All matters of importance and most financial questions have to be referred by factory to Director, thence to Director-General and by him to the Army Department, which usually has to refer to the finance authority. When the matter leaves the Director's office, it leaves the sphere of technical knowledge, as the education and training of the officials in the Army and Finance Departments have had no connexion with manufacturing methods and conditions. As a result factory accounts, finance, methods and rules have been squeezed within a system devised for branches of the army having nothing in common with a huge manufacturing organisation. Under the Munitions Board there was considerable improvement, as, the Board being itself a Department of Government, the head of the factories had direct access to the ultimate authority; but the temporary nature of the Board militated against permanent changes.

In the old records occur many protests against the administrative system, and its rigidity, centralisation and expense must always have hampered the local executive. There have been many Commissions and Committees, but they do not seem to have got to the root of the trouble. A hundred years ago the standard of public morals was extraordinarily low, and to-day the administrative system appears to be still based on the theory that elaborate regulations and multitudinous checks and counter-checks are needed to prevent fraud. Though a factory superintendent no longer has to attest on oath that he has derived no profit other than his salary, direct financial responsibility is still withheld, accounts are still the masters of management, while regulations become more detailed and voluminous every day, crushing initiative.

True economy in the Army can never result from a cutting down of fighting strength or proper equipment, nor from delays in improving conditions of service; it will come only from a complete overhaul and reform of administration in all branches. One-hundred years ago an army went on service in India with huge crowds of camp followers, even a subaltern has recorded that he had carts and elephants for his baggage, which included a pipe of madeira, in the campaigns of Lord Lake. Crowds of followers no longer hamper the mobility of the forces in the field; but a horde of non-fighting officials, great and small, has settled in every branch of the military service and eats up a huge and disproportionate part of the Army's budget. The business of the Army must be conducted on business lines by men trained for the work and it must be separated from the duties of commanding and of training the fighting units.

A curious feature of Indian administration is its lack of co-ordination and co-operation. While Local Governments were urging employers to improve the housing of their workers, money for sanitary lines for the Ordnance Factories was not forthcoming, though serious loss of output from absence through sickness was clearly shown. When a high Education official wrote an appreciative account of the education facilities provided by certain private mills, the Government factories had no such facilities. When railways were being forced to make better arrangements for the supply of food to their Indian passengers, the Factory Administration was censured for incurring expense in providing space and sanitary fittings for the sale of food to the workers in one factory.

India has allowed industrial towns to develop without much attempt to avoid the evils which any study of the growth of industrialism in Great Britain would have shown to be inevitable unless precautions were taken. Working conditions in many factories, and living conditions in most industrial centres, are most unsatisfactory and far from creditable to the Government of the country.

The Ordnance Factories were the pioneer industrial establishments in India, and to-day they hold a leading place in equipment, organisation and methods and also in variety and quality of production. They can be and might be made a pattern in every respect to the industries of the country and they can and should lead the way in the technical education of the Indian.

Manufacturers in India are asking for protection and the Commission which is now sitting is receiving much evidence of the impossibility of industries facing overseas competition without high protective duties. It is obvious that India imports much which it could itself manufacture, that it exports material which should be worked up in the country, yet labour is cheap, most materials are available at a reasonable price, land can usually be obtained at a moderate cost and a huge market is close at hand. Why cannot industries using local materials compete with imports from thousands of miles overseas? There are several reasons, but one of the chief, in my opinion, is the cost of management and of skilled supervision, which often swamps the cheap factors. Labour is cheap individually but is dear in the mass, because it is uneducated and needs, for efficient output, a high proportion of skilled supervision. Such supervision has to be mainly European and is most costly, and where money is saved by limiting this class of supervision, more money is lost in quantity and quality of output. Competition with Europe, except under certain favourable circumstances, is impossible for the ordinary Indian factory till the educated Indian has been trained to supervise mechanical work and to take a proper share in the management of industrial establishments. The eight great Ordnance Factories provide an ideal training ground for this purpose and many schemes have been put forward from time to time, and I believe one has at last been sanctioned. If this scheme is broadly conceived, with provision for the training of lads in character as well as for technical education, and if it is for industry generally and not merely for the Government factories, and if the cost is not thrown entirely on the Military Budget, then it will be of the highest importance in the progress of India.

Complete Indianisation of industrial management is impossible, however, in the near future, and it will never be possible till a generation of educated Indians arises, trained in mechanical and engineering sciences, experienced in subordinate management and having the power of studying and of assimilating the industrial progress of other countries. European supervision and management in India is by no means entirely satisfactory, owing to the difficulty of combining up-to-date technical knowledge with experience of Indian conditions. It is distinctly difficult in India to keep in touch with the rapidly changing ideas and methods of the modern industrial world. Competition is too keen to permit of any falling behind and industrialism in India has a constant struggle with the climate and other conditions which exercise an enervating influence on the vast majority of people, both Indian and European.

One important matter which must be touched on is preparation for war. No country can maintain adequate munitions factories in peace time, and in India, where there are no private ordnance factories, the Government establishments must be treated as a cadre, which on mobilisation will be filled out by the commercial workshops. During the later years of the war every effort was made to obtain supplies of war material from private factories but the results were disappointing, due to three causes—there was no power to insist on war work being undertaken, there was hardly a shop which could turn out the accurate work required, and the Ordnance factories were not able to supply the necessary tools, gauges, drawings and assistance. Any sound scheme for the expansion of munitions supply on the outbreak of a great war must ensure, first, that the Ordnance factories are so equipped and organised that they will be able to supply, and continue to supply, gauges, drawings, special tools and materials and assistance for all work which can be done in private shops; second, that private works have such special plant as may be necessary and have annual practice in the work which will be required of them in war time. The special plant might be provided by Government and be used for private work, on condition of its being kept in order and of the staff being periodically trained in war work. The scheme should also provide for a study of the resources of the country, in plant, stocks of goods and materials and also possible sources of supply of raw materials.

It is obvious, I think, that the suggestions made can never be adopted so long as the Ordnance Factories remain purely military and are administered as a somewhat obscure branch of the Army. My view is that all military manufacturing establishments should be brought under a department of Government dealing with supply and be treated as factories and not as branches of the Army. This need not affect military preparation in any way, as Government, acting on the advice of its military experts, would authorise the stocks of equipment and of material to be maintained and would indicate the manufacturing capacity required from the various factories.

I have only touched on the fringe of my subject and have had to omit much of interest in the history of the factories. I am convinced that, in a country like India, the Government factories must be used to the fullest extent in the development of industry on sound lines. Moreover, I am certain that their efficiency will be greatly increased if their financial needs do not have to compete with the requirements of every other part of the military organisation. I have no doubt whatever that considerable economy will follow if their accounts are treated as industrial and not as military accounts, and if they are placed in closer touch with the ultimate authority.

I doubt whether any branch of the public service in India worked harder or more thoroughly during the war than the Ordnance Factories, certainly no other branch excelled it in economy. My reading of the records and my experience of 28 years in the Ordnance Department lead me to the conclusion that India has usually had far better service from its factory officers than it has paid for. The present age is a logical and material one and the class of man willing to give more than he receives is rapidly vanishing. The Ordnance Factories are a vital link in the defensive chain of India and if they are to be an efficient link, far more attention must be paid to the well-being of the human element. I am proud that I was connected with these factories for nearly 26 years, that I was in charge of their administration for three strenuous years, and that I have had the honour to-day of giving you even this inadequate account of their history and their work.

DISCUSSION.

THE CHAIRMAN, in referring to that portion of the paper which mentioned Sir Arthur Wellesley, and the reflections made on the Arsenal at Seringapatam, said he had in his hands the original document written by Wellesley himself. He had evidently been nettled at the reflections which had been made, and the following was the letter he wrote:

"CAMP, JULY 15, 1803.

SIR,

I have had the honour of receiving your letter of the 27th June, with its enclosures, being letters from Major Norris, upon the subject of the failure of a gun shed constructed by him in the Arsenal of Seringapatam.

I have not with me at present the copy of the Report of the Committee which surveyed the buildings in the Arsenal in October, 1801, nor have I a recollection of the particulars of that Report, or of the state of the buildings which occasioned it. I can answer for myself that I had no intention to cast a reflection upon Major Norris or upon any other officer, or to give the Military Board any impression excepting one of the real state of the buildings examined. I believe the other members of the Committee acted with the same views.

In respect of the gunshed in question, I have to observe that Major Norris, in his letter to the Court of Directors of the 24th November, 1802, declares that the materials employed in its construction were taken from old buildings, and that it could not be expected that they should be good, and that the artificers who built it were very bad workmen. It is probable, therefore, that if he had been a member of the Committee which surveyed the building in 1801, he would have agreed with the other members in the Report which was made.

That shed, as well as other buildings in the Arsenal, must have suffered from the Monsoon in 1801; but as well as I recollect, the Committee remarked that it should be pulled down and re-built with fresh materials, which was the cause of the special report on the subject of its materials and workmanship. The other buildings had suffered only from the monsoon and required what appeared trifling repairs.

I perfectly recollect that stores were placed on the beams of that shed, as I believe they are in every shed in the country, but I never imagined their weight was greater than the beams ought to have borne, otherwise the stores should not have been placed there.

(*Signed*) ARTHUR WELLESLEY, M.G.

The Secretary of the Military Board."

He (General Barrow) thought it might interest the audience to note the personal care which Sir Arthur Wellesley expended on everything that came before him. He had written that letter with reference to a Department under his Command at the time.

COLONEL J. H. LAWRENCE-ARCHER, C.I.E., Ordnance Consulting Officer, India Office, said General Young's paper was mostly historical, and discussions on historical matters were usually either very dull or very controversial. He thought, however, there were a few things which could be learned from the history of the Indian Ordnance factories. One was that those factories had had the same difficulties as everybody else in India had had. People always blamed the Finance Department when they wanted money and did not receive it; but it was a matter of allocation. They got all the money which the nation could afford, and it was in the allocation of that money by the people who were responsible for it that those who needed it were "done down" as they thought. The audience had heard a description of the Indian Ordnance factories, and all that they had done. Not very much had been said about Indian industries. One thought things outside the factory were perhaps small matters—such as the boiling of soap, the making of aluminium hollow-ware, and a hundred-and-one other articles with which the factories were not directly concerned. It struck him that it was perhaps more in the direction of what he might call Ordnance engineering that the Indian Ordnance factories appeared at their best, though as examples of what can be done, they might have their use to industrial establishments; but they were in a peculiar position. They were not like independent industrial concerns; their aim was to produce articles which should be identical in quality, appearance, and in every respect with those produced by the Royal factories at home —Woolwich Arsenal, for instance. They in India came to Woolwich for directions in every possible way; they tried to follow Woolwich even in the methods of manufacture throughout, so that, in the end, their products might be the same as those of Woolwich, and be used throughout the Empire wherever mixed Forces had to operate together. He thought it would be a good thing if a little more liaison could be obtained between the personnel. He had attended prize distributions at Woolwich and had heard the young engineer who had been trained at Woolwich urged to go beyond the walls of Woolwich Arsenal out into the world in order that he might gain experience and breadth of mind; and it seemed to him (the speaker) that it would be a very good thing for some of these young engineers if they could be sent out to the Indian Ordnance factories with a reasonable assurance that if they behaved themselves and fulfilled the promise of their education, they would be received back again and allowed to resume their job. After all, it would be perfectly easy to send a man of 25 out and to allow him to return when he was 30 and to replace him with a man of 30, who should come home when he was 35 after a five years' tour, and so on. Difficulties would no doubt arise in the case of men of older ages because of certain pension and retiring conditions, but he had no doubt those difficulties could be overcome. The Indian Ordnance factories had adopted apprenticeship schemes and were working hard at them, but there was one great difficulty. At home there were Polytechnics which had professors who taught mathematics. British factories had not to have their foremen going round initiating the lads in the mysteries of the binomial theorem. In India the factory staffs were now actually conducting the education, not of British lads but of Indians, and it would be easily recognised what an extraordinarily difficult task they had. He hoped in the few remarks he had made he had given a lead to an interesting discussion.

SIR ALFRED CHATTERTON, C.I.E., Assoc. M.Inst.C.E., M.I.M.E., thought the author had made out his case that the ordnance factories of India were the pioneers in India of modern industrial developments. They dated back to more remote periods than any other modern industrial organisation in the country. Among his earliest recollections of India were some of these ordnance factories. When he first went to Madras his own offices had been just opposite the Gun Carriage Factory, and he became acquainted with the then Superintendent, Major Fletcher. He frequently went into those factories to see what was going on. Later, when he was endeavouring to introduce the manufacture of chrome leather into India, he became acquainted with the personnel of the factories in which the manufacture of harness and the tanning of leather was carried on, and at about the same time he was associated with General Babington, who was then superintendent of the Cordite Factory at Aruvankad, in the preparation of proposals for the manufacture of acetone in India. With General Babington he had spent a good deal of time over the scheme. The details were worked out to provide acetone for the cordite factory and charcoal for general use, but eventually they had been turned down, partly because of the opposition of the Madras Chamber of Commerce to Government intervention in the matter, and partly owing to the idea which prevailed in Simla that there was no necessity to incur the large capital outlay which the proposals would involve, as the necessary supplies of acetone could then easily be obtained from Germany. Subsequently, as a member of the Indian Industrial Commission, he saw nearly all the other ordnance factories at one time or another, and he was, therefore, in a position to appreciate the difficulties which the officers of the Indian Ordnance Department had to overcome in developing their plans, and he could very heartily congratulate them on the extremely valuable results they had achieved during the period of the war. General Young had shown that in India, as in England, the problem of the munition supply of the country during wartime was one of extreme difficulty. In addition to the difficulties of which the author had spoken, it was probable that future Ordnance officers would have to deal with the question of chemical warfare. That would introduce a new series of problems, and, it was possible, might bring the Ordnance factories still more closely into association with the industrial life of the country.

He was in entire agreement with the author that the greatest obstacle to progress in India was the lack of local Indian engineering talent. Until that was supplied it was perfectly certain that any large and widespread industrial development was impossible, for the reason that in any attempt to compete with foreign manufacturers, although labour was cheap, the cost of supervision was high, and until a very much larger amount of indigenous talent was available in the workshops, and in the higher grades of the administration, the cost of mechanical engineering and analogous forms of primary industrial enterprise in India must necessarily be much higher than it was at home.

One thing the Indian Ordnance factories had had to consider was that of training Indian workmen. It was very greatly to the advantage of India that the Ordnance Department had succeeded in training them to turn out work with the extreme degree of accuracy necessary in modern rifles and ordnance.

It would be a matter, he thought, of interest, and possibly of very considerable value to the country, if Ordnance officers would endeavour to ascertain whence their labour came—whether the artificers in those factories were all hereditary artisans by caste, whether they came from particular districts, whether they were the outcome of the development of railway workshops in the various railway centres of the country, or whether they were just drawn from the ordinary mixed community which congregated in every large town. Nothing very much was known about where those people came from, and it would probably simplify the educational problems of the future if a little more attention was paid to that particular aspect of the labour question.

Another point which Ordnance factories had demonstrated in India was the possibility of mass production of standardised articles. One of the real difficulties which pioneers of industries in India had to face was the fact that the Indian consumer offering only a very limited market could exercise his own idiosyncracies to an extraordinary degree in the choice of goods that he purchased. He had the supplies of the world open to him, and when he wanted a particular article he could select from dozens of manufacturing firms, all producing articles more or less of the same character but differing in minute detail. So long as that wide choice was allowed to the consumer he would be content to get his goods from abroad. If some system of standardisation could be introduced so that mass production became possible, and the choice of goods was restricted by suitable tariffs, then it would be very much easier to develop manufacturing and industrial concerns in India. For instance, so long as a man could choose from the various range of motor cars made in Europe and America, it was hardly likely that a single factory in India, turning out one particular line of car, would have any prospect of commercial success. The ordnance factories had very clearly proved that the highest grade of production was possible if the work was carried out on a sufficiently extended scale, and, apart from any other work that they had done, that result was of extreme value.

DR. J. AUGUSTUS VOELCKER remarked that among the branches of the subject which General Young had dealt with there was one that he had not specially treated of, but to which he (the speaker) as a chemist perhaps might be allowed to refer. The author had told the audience, very rightly, how, at the time of the breaking out of the war, India had failed badly in providing a number of materials of warfare which it might very properly have done, and he had referred also to points of error in administration and to the need of taking a wider view. On all those points he was thoroughly in agreement with General Young. If there was one thing which had been apparent in the last war it was the dependence of our country upon chemical research. That could not be better illustrated than by the noble work of Lord Moulton and his colleagues, and by remembering how great a share these experts had had in bringing about the ultimately successful end. As a member of the Council of the Institute of Chemistry he had been one of those who for a long time had urged upon the Government of India the better recognition of chemists in India. At that time the Council of the Institute of Chemistry had been constantly receiving representations from the men who had gone out as skilled chemists to India to work in the Ordnance Department, as to the position they held, their status, and their prospects of advancement and retirement. These complaints had been so constant and repeated that the Council of the Institute of Chemistry made very strong representations. In future it would be well, he thought, that more attention should be given to that point. What had been found was that those who had gone out, although they went as experts, on their arrival were treated as very little better than workmen. How could it be expected that such men, with such poor prospects, could do very much in the way of advancement of chemistry as applied to ordnance work? He believed that, as a result of the representations made, some improvement had been effected, but he did think that in the present day, when the Ordnance Department was putting its work into order, the point he had just mentioned should not be lost sight of.

THE CHAIRMAN, in proposing a hearty vote of thanks to General Young for his paper, said it must have been interesting to all present, because it had not been too technical for those who had no knowledge of the technicalities of ordnance work. There was one remark in the paper which he could not help criticising, namely, that very few high officers of Government ever went to see the various ordnance establishments, and that when they did go they only stayed at the most half an hour. Personally, he had a vivid recollection of a very hot day at the end of March or the beginning of April accompanying Lord Curzon on a visit to either the Cossipore or the Ishipore factory. The visit lasted over an hour and a large number of very pertinent questions were asked by Lord Curzon. He also remembered going round the Pindi Arsenal with another highly distinguished officer, Sir William Lockhart. He would like to say one word about Lieut.-General Stewart of the Bengal Artillery, who was for 20 or 30 years at the Cawnpore Arsenal. Everybody who knew him had the greatest respect for him as a friend, and the greatest admiration for all the good work he did in starting tanning and other industries in Cawnpore. The Indian Ordnance Department had done great work in India—a work which, he thought, had hardly received due recognition. As had been seen on the screen that afternoon, important Government factories had spruug up all over India, and the photographs indicated what big concerns they now were. In the old days they were mostly on a very small scale. The Indian army and the Indian Government had for many years been entirely dependent on the Indian Ordnance Service for the supply of their armies in the field. A great deal of gratitude was due to that Service, whatever criticism it might have received in the press in the dark days of the late war. It had to be remembered that no one contemplated so big a war; and no one should therefore be blamed because those institutions had been wanting when the war began. Even Cabinet Ministers had failed to grasp the fact before August, 1914, that we were up against the greatest war of history.

THE EARL OF DENBIGH, C.V.O., Colonel Commanding Hon. Artillery Co., in seconding the vote of thanks, said that his experience of India was limited to serving in the Horse Artillery there some

30 years ago. but, from very reliable sources, he had heard a great deal about what was going on there, and the paper of General Young was very much to the point, especially with regard to the penny-wise and pound foolish policy which seemed to have permeated Indian administration to an even greater extent than it had done in many of the Departments at home. General Young drew attention to the necessity of separating civilian manufactures from the Military Department. The administration of factory work was a science in itself. The business of the Army must be conducted on business lines by men trained for the work, and it must be separated from the duties of commanding and training the fighting units. He hoped that some of the author's remarks in the paper would be taken to heart by others. Many stories had been related of the extraordinary way in which Indian red tape sometimes operated. A well-known and distinguished general officer had told him how, when a junior officer, he had been on the Quartermaster General's staff in one of the frontier expeditions, and part of his duty had been to buy local supplies from different villages. It could be quite understood that a business of that sort had to be conducted in a somewhat rough-and-ready manner; and the officer to whom he was referring could not do more than send in his indents for cash at different times. The obtaining of receipts and the keeping of proper accounts under the circumstances had been practically impossible. Two years after the campaign had finished, when the accounts of the campaign had been gone through by the finance people in India, this officer had been confronted with a demand for receipts for all the money he had expended in the purchasing of the various supplies. He replied that under the circumstances it was impossible for him to produce them. The reply was, "We are very sorry, but in that case we must make a personal demand upon you to return the money." and he was presented with a bill for £19,000. The officer told him that he settled the matter forthwith by sitting down and writing a cheque for £19,000 on the Army bankers, Messrs. Cox and Co., and sending it in. As it had been well-known that his balance, if there was any at all, was probably more like £19 than £19,000, the Finance Authorities had seen the absurdity of their position. The cheque was never presented and the officer heard no more of the matter.

The motion was carried unanimously, and the meeting terminated.

THE FORESTS OF KENYA COLONY, WITH SPECIAL REFERENCE TO SOME WOODS OF ECONOMIC VALUE.*

By R. St. Barbe Baker (Late Assistant Conservator of Forests, Kenya Colony).

Kenya Colony, formerly known as British East Africa, has a total area of about 245,000 square miles, or roughly speaking twice the size of Great Britain. Although the forest area has not yet been accurately determined, I estimate this to be approximately 2,200 square miles, apart from the extensive areas of bamboo. The most important forests are situated in the Highlands which at one time must have been largely covered by virgin forests; now, as a result of the continuous inroads made by a native agricultural community, these have largely disappeared. The progressive methods of agriculture in the absence of sufficient natural or artificial fertilizer, and the knowledge of crop rotation to secure the recuperation of the soil have accounted for the devastation of vast forest areas. Already in some parts of the native reserves there is a fuel famine and the natives have to travel long journeys to fetch wood.

The small percentage of forest land to the whole area might well give cause for alarm and offers a problem requiring concerted action by the local Forest Department and the Administration. Although a Forest Department has been in existence for a considerable time, little has been done to effect a method of regenerating indigenous species on a comprehensive scale.

In my short experience of two years in the Forests of the Colony I was very handicapped because so little information was available as to yield: in fact no attempt has been made to fix the yield in any way, and there are no working plans.

The virgin forests contain a very large percentage of trees past their prime and, though losing their value each year, they are allowed to stand. The so-called "selection system" generally in vogue is very rough and ready. Timber is felled and extracted by purchasers under leases, licences, or permits, and in all there are about 35 concessions. In practice the selection is actually done by the miller or his agent and not by the forester. The result is that most of the over-matured badly grown and hollow trees are left standing while the best are removed for exploitation. In time the over matured trees fall over and increase the risk of fire or a dense undergrowth, and the absence of suitable seed trees prevents natural regeneration. As far as I could estimate in the virgin forest there is no increase, the annual growth being about balanced by the annual decay. Much of the overmatured forest consists of cedar (*Juniperus procerus*). This is a large evergreen tree, generally found from 60 to 70 feet in height, though under the most favourable conditions it attains to a height of 130 or 140 feet, girthing up to 18 feet. This variety thrives best on mountain slopes at an elevation of from 6,000 to 9,000 feet where there is a rainfall of 40 to 50 inches. Cedar seems to thrive best in mixed forests with *Mu Tamayu* (*Olea chrysophilla*) Olive, *Mu Sengera* (*Podocarpus gracilor*) and (*P. milanjianus*), *Muziga* (*Warburgia ugandensis*) or "greenheart,"

---

*Reprinted from the *Journal of the Cambridge University Forestry Association*, December, 1923.

Musaizi (*Weihea Africana*) or "Pillar wood," *Mushami* (*Allophyllus abyssinicus*) or "Chestnut," while *Trichocladus ellipticus* (Wych hazel) forms a considerable part of the undergrowth, especially in the more moist places. I have observed that in pure or almost pure, forests, cedar is much smaller and inferior. The Kenya cedar, although somewhat harder than the American pencil cedar, has all the qualities for making the best pencils. Experiments are now being carried out to perfect a softening process and already success has been met with. To-day several firms are manufacturing pencils from slats imported from Kenya. In the past the bulk of this pencil cedar has come from America, but this source of supply is said to be dwindling and may soon be barred by tariffs; however, there are sufficient supplies of Kenya cedar available to keep up a sustained export in pencil slats and there is no reason why this should not become the chief source of supply for the world.

So far as is known at present cedar is the principal timber likely to be exported in any quantity. Indeed, the Highlands of Kenya may never export timber in bulk owing to the lack of large enough rivers for floating and the high cost of freightage over a long railway journey. Attention should, however, be paid to such varieties as can be utilised for special purposes on the European and American markets. Apart from the one exception of cedar from the Highlands, perhaps the Coast Forests, including the mangrove swamps, afford greater possibilities for the export of timber. Mangrove poles (*boritis*) are amongst the chief exports. The shortage of building material in Persia and Arabia has created a demand for Coastal woods and when the *Moosim Dhows* bring produce to Zanzibar, they call at Milindi and Lamu on their return journey where they pick up mangrove poles in very considerable quantities.

The chief commercial species is locally known as *M'koko*, this is *Rhizoprora mucronata*, while another mangrove of importance is *Ceriops candolleana*. Besides providing building material both for export and the use of the Coast natives and Arabs, the mangrove swamps yield annually large quantities of fuel and bark for tanning.

The land forests of the Coast rise to an altitude of about 1,000 feet, and contain several valuable species of heavy hard woods, which may be of considerable economic value. The chief forests are the *Witu* Forest and the *Arabuko Sokoki*. They contain such trees as *Bembakofi* (*Afezelia quanzensis*) a heavy hard red wood used largely by the Arabs for doors. It can be obtained in planks up to 2 feet in diameter. *M'tanderusi* (*Trachylobium Hornemannianum*) which provides the well-known gum Copal, is also an excellent timber and can be found in large sizes. *Muhuhu* (*Brachylaena Hutshinsii*) is used largely by the Arabs for ceiling beams, and is hard yellowish aromatic wood of some importance. "*Tamarindus indica*" is quite common and might be useful to export for tannery purposes. In England this is popular for making policemen's truncheons and surgical appliances.

The scrub forests of the Coast contain an excellent substitute for ebony in *M'pingo* (*Dalbergia melanoxylon*) African blackwood. Parcels of this wood have already been imported into Europe and have fetched about the same price as ebony. There are also woods which may be suitable as substitutes for boxwood.

As an example of the ignorance which exists of the forest resources of the Coast, it is interesting to note that in the construction Harbour at Kilindini woods from South America are actually being used when a plentiful supply of suitable material easily accessible is within about 150 miles. It is also strange that the new Government Railway on the Uashin Gishu Plateau should be laid on *steel* sleepers and passes through a creosoting yard in virgin forests containing many varieties suitable for sleepers. Again it is hard to explain why huts for workmen should be brought from Norway and constructed in clearings made in the Forests.

A classical instance of Government folly was the construction of a bridge on the Mara River with Baltic pine. This was shipped via London to Kilindini from whence it was transported along 374 miles on the Uganda Railway to Kijabe, where it was met by porters, who carried it on their heads for another hundred miles, to the place where the bridge was finally constructed, hard by a virgin forest containing many species of more suitable woods. Very soon after completion the timber was attacked by bores and fungus, and soon became unsafe and a passing herd of elephant seemed to take great delight in completing the demolition.

Fortunately, there is an increasing tendency to utilise home grown timber, although far too much is at present imported. Better attention will have to be given to seasoning. Carelessness in this respect accounts for much of the prejudice against indigenous varieties which have frequently been adversely compared with imported timbers. Organised research work is urgently required in all branches of forestry and little progress will be made until such time as those officers with a recognised training supersede some of the old timers who, in spite of longer service, possess little practical or technical knowledge.

The first essential is a complete knowledge of Forest Principles which can, with a little experience, be applied to local conditions whatever they may be.

GENERAL NOTES.

International Competition of Designs for Linoleum.—Under the auspices of the *Arte Pura e Decorativa*, an international competition of designs for linoleum will be held at Milan. The designs must reach the "Direction de Revue *Arte Pura e Decorativa*," Via Ciovasso, 4, Milan, not later than the end of March, 1924. The following prizes are offered: one first prize of 5,000 lire; one second prize of 3,000 lire; three third prizes of 1,000 lire each; and other prizes amounting to 4,000 lire. Further particulars can be obtained from the address given above.

The Teak Plantations of Milampur, Southern India.—An account of these plantations was recently given by Mr. R. Bourne, of the Oxford School of Forestry, to the Cambridge University Forestry Association. They were begun in 1840, and have, therefore, passed through all stages, and been regenerated. Their origin was due to need of timber for the Bombay Naval Dockyard, being the first attempt to form forests in India. The silviculture of Teak demands preservation of the qualities of the locality, and so an evergreen understory is necessary. The growth in a short period is very rapid, and accompanied by prolific weed growth, and as weeding has to be carried out, the problem is to do this in the cheapest manner. Tungya cannot be employed as in Burma, because there are no tribes that grow crops on the forest ground. Artificial planting is far cheaper, owing to the regular espacement making the cost of weeding 7s. 6d. per acre, as compared with 40s. when natural regeneration is used. Teak produces much light seed each year, which is collected. The area for regeneration is clear felled, and burnt over to oxidise any acids in the top layer of soil, and destroy roots and seedlings of weeds, thus saving weeding during the first year. Planting is 6ft. by 6ft., and requires a thinning, that is unsaleable, in the third year. A wider espacement resulted in 50 per cent. of the trees being forked at 20 feet, and so had to be abandoned. Weeding is very easy owing to the position of the seedlings being known. The first thinning takes place at 4-6 years, and is mechanical to give an even espacement.

American Settlers in Canada.—According to the Commissioner of the Dominion Immigration Department, during the past year approximately 6,000 Americans have settled in Canada. Their capital is estimated at nearly £250,000. Settlement has, during recent years, been unusually heavy along the newer transcontinental line. One reason given for this is that prosperity is infectious, and that the American settlers are well satisfied with the conditions and opportunities they find in Canada. The tide of emigration from Canada to the United States, on the other hand, is beginning to ebb. Although the population of Alberta has increased from 73,000 in 1901 to nearly 600,000, there are still 108,100 quarter-sections (of 160 acres each) available for free homesteads. The Province has arable land estimated at 72,000,000 acres, of which only 10,550,000 are at present under cultivation.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 6.—Iyemasa Tokugawa, O.B.E., First Secretary to the Japanese Embassy, "The Earthquake and the Work of Reconstruction in Japan." (With Cinematograph Illustrations.) Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

February 13.—H. Maxwell-Lefroy, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle." Sir Aston Webb, K.C.V.O., C.B., P.R.A., will preside.

February 20.—Percival James Burgess, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber."

February 27.—Charles S. Myers, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation."

March 5.—Major-General Sir Fabian Ware, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries."

March 12.—Alan A. Campbell Swinton, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.) Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., will preside.

March 19.—R. L. Robinson, Member of the Forestry Commission, "The Forests and Timber Supply of North America." Lord Lovat, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., will preside.

March 26.—Neal Green, "The Fishing Industry and its By-Products."

April 2.—Sir Lynden Macassey, K.B.E., "London Traffic."

APRIL 9.—FRANK HOPE-JONES, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum."

APRIL 30.—BRIGADIER-GENERAL SIR HENRY MAYBURY, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "Roads."

MAY 7.—J. ROBINSON, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

Dates to be hereafter announced :—

T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MRS. ARTHUR MCGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons at 4.30 o'clock :—

FEBRUARY 15.—SIR RICHARD M. DANE, K.C.I.E., Commissioner, North India Salt Revenue, 1898-1907, and Inspector-General of Excise and Salt for India, 1907-09, "Salt Manufacture in India." THE RT. HON. LORD MESTON, K.C.S.I., LL.D., will preside.

MAY 2.—JOCELYN F. THORPE, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced :—

BHUPENDRA NATH BASU, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons at 4.30 o'clock :—

FEBRUARY 5.—F. W. WALKER, "The Commercial Future of the Backward Races, with Special Reference to Papua." SIR GEORGE R. LE HUNTE, G.C.M.G., will preside.

MARCH 4.—THE HON. T. G. COCHRANE, D.S.O., "Empire Oil: The Progress of Sarawak." THE RT. HON. LORD BEARSTED will preside.

MAY 27.—C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

CANTOR LECTURES.

ERIC KEIGHTLEY RIDEAL, M.B.E., B.A., Ph.D., D.Sc., F.I.C., The Chemical Laboratory, The University, Cambridge, "Colloid Chemistry." Three Lectures.

SYLLABUS.

LECTURE III: FEBRUARY 4.—Emulsion Colloids. Preparation and Stabilisation. Coal tar disinfectants, Milks, Phase inversion-biological importance, greases, antigens. Soaps. Ionic micellae.

Adsorbing Gels. Silica gels, ferric oxide and alumina, clays, vaseline, rubber and textiles. Membranes, permeability. Equilibria at membranes, application to leather.

EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

COBB LECTURES.

Monday evenings, at 8 o'clock :—

DR. T. SLATER PRICE, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31 ; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, FEBRUARY 4..Transport, Institute of, at Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C., 5.30 p.m. Mr. R. J. Howley, "Road Transport in Relation to the General Transport Problem of the Country."

British Architects, Royal Institute of, at the Royal Society, Burlington House, Piccadilly, W., 8.30 p.m. President's Address to Students.

Engineers, Society of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Presidential Address by Mr. G. A. Becks.

Chemical Industry, Society of, at the Chemical Society, Burlington House, Picadilly, W., 8 p.m.

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal Meeting). Mr. F. W. Crawter, "Storage Battery Troubles."

Royal Institution, Albemarle Street, W., 5 p.m. General meeting.

Farmers' Club, at the Surveyors' Institution, 12, Great George Street, S.W., 4 p.m. Prof. R. H. Biffen, "Modern Wheats."

University of London, University College, Gower Street, W.C., 5.15 p.m. Mr. A. S. Parkes, "The Mammalian Sex-Ratio." (Lecture II.)

At King's College, Strand, W.C., 5.30 p.m. Rev. C. P. Rogers, "Ecclesiastical Music." (Lecture I.)

6 p.m. Mon. R. Nathan, "Dix Années de Recherches : le théâtre libre" (in French).

5.30 p.m. Dr. R. W. Seton-Watson, "A Survey of Bohemian History." (Lecture I.)

TUESDAY, FEBRUARY 5..Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. A. Dendy, "What is Heredity ?" (Lecture II.)

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. The Secretary, Report on the Additions to the Society's Menagerie during the months of November and December, 1923. 2. Dr. N. S. Lucas, Report on the Deaths which have occurred in the Society's Menagerie during 1923. 3. Mr. C. T. Regan, "Reversible Evolution, with Examples from Fishes." 4. Mr. M. A. Smith, "New Tree-Frogs from Indo-China and the Malay Peninsula." 5. Mr. R. R. Mole, "The Trinidad Snakes." 6. Mary L. Hett, (i.) "On the Family Linguatulidæ." (ii.) "Zoological Results of the Third Tanganyika Expedition conducted by Dr. W. A. Cunnington, 1904-1905: Report on the Linguatulidæ."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Address by Mr. A. L. Coburn.

Anthropological Institute, at the Royal Society, Burlington House, Piccadilly, W., 8.15 p.m. Mr. W. E. Armstrong, "Rossel Island Money."

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

Alpine Club, 23, Savile Row, W., 8.30 p.m. Mr. R. P. Bicknell, "Jungfrau, Schallgrat and other Climbs in 1923."

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. J. H. Helweg, "Modern Danish Lyrics, 1870-1920." (Lecture I.)

5.30 p.m. Mr. N. H. Baynes, "The Roman Empire and its Invaders." (Lecture I.)

8 p.m. Miss E. J. Davis, "The City Churches and their Endowments." (Lecture I.).

At King's College, Strand, W.C., 5.30 p.m. Sir Bernard Pares, "Russia before Peter the Great to 1861." (Lecture III.)

5.30 p.m. Dr. H. W. Carr, "The Transition to the Relativist Conception of Nature." (Lecture I.)

5.30 p.m. Mr. J. R. Beard, "Electric Power Mains." (Lecture II.)

5 p.m. Prof. F. C. Burkett, "Christian Beginnings." (Lecture I.)

Physiology, London College of, 8, Taviton Street, W.C., 8 p.m. Dr. J. Lambert, "Camouflage in Nature · Protection of Animals and Insects."

WEDNESDAY, FEBRUARY 6.. Anglo-Batavian Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Mr. F. G. Keiller, "The Malay Archipelago."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. (Wireless Section.) Mr. E. B. Moullin, "Atmospherics and their Effect on Wireless Receivers."

United Service Institution, Whitehall, S.W., 3 p.m. Lieut.-Col. D. E. Robertson, "The Organisation and Training of the Army in India."

Public Analysts, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1. Annual General Meeting. Presidential Address. 2. Mr. C. A. Mitchell, "Osmium Tetroxide as a Re-agent for the Estimation of Tannins and their Derivatives." 3. Mr. G. D. Elsdon, "The Composition and Examination of Beef and Malt · Wine." 4. Mr. S. A. de Lacy, An Apparatus will be Demonstrated for Fat Extraction and Solvent Recovery.

Economics and Political Science, London School of, Houghton Street, Aldwych, W.C., 6 p.m. Dr. A. P. Newton. "The Founding of the British Empire."

Archæological Institute, at the Society of Antiquaries, Burlington House, Piccadilly, W., 5 p.m. Mr. F. J. Lovegrove, "The Cathedral Church of Llandaff."

Sanitary Engineers, Institution of, Caxton Hall, Westminster, S.W., 7.30 p.m. Dr. W. Rushton, "The Life Present in a Stream and the effects of Sewage and Various Trade Wastes on it."

University of London, University College, Gower Street, W.C., 5.30 p.m. Prof. P. Geyl, "Mediæval Dutch Drama."

5.30 p.m. Mr. I. C. Grondahl, "Contemporary Norwegian Literature." (Lecture I.)

5.30 p.m. Mons. P. Vitry, "Les Sculptures de la Cathédrale de Reims." (In French.)

At the London School of Economics, Houghton Street, Kingsway, W.C., 5.30 p.m. Mr. F. J. C. Hearnshaw, "The Political Expansion of the Empire."

At the University, South Kensington, S.W., 5 p.m. Sir Frederick Bridge, "Some Shakespearian Studies" (Lecture III.)

At King's College Strand W.C. 5.30 p.m. Mr. A. F. Kendrick "The Artistic Background of Mediæval History." Textiles.

THURSDAY, FEBRUARY 7.. Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Squadron-Leader R. B. Maycock, "Airmanship at Sea."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. Sir William Bragg, "Recent Research in Crystalline Structure." (Lecture I.)

Mechanical Engineers, Institution of (Midland Section), Technical Institute, Coventry, 7.30 p.m. Mr. R. Jackson, "Pulverised Coal, its Preparation and Utilisation."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Linnean Society, Burlington House, Piccadilly, W., 5 p.m.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. Messrs. N. V. Sidgwick and R. K. Callow, 1. "The Solubility of the Aminophenols." 2. "Abnormal Benzene Derivatives."

British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. H. G. Dowling, "Modern Considerations attaching to Wall Paper Decoration."

Economics and Political Science, London School of, Houghton Street, Aldwych, W.C., 5 p.m. Sir H. L. Smith, "The Economic Laws of Art Production." (Lecture IV.)

University of London, University College, Gower Street, W.C., 5.30 p.m. Senator Prof. Antonio Cippico, "Il Poliziano."

5.30 p.m. Mr. I. Björkhagen, "Modern Swedish Prose Authors." (Lecture I.)

5.30 p.m. Prof. J. E. G. de Montmorency, "Comparative Customary Law of Europe and Asia." (Lecture III.)

At King's College, Strand, W.C., 5.30 p.m. Prince D. S. Mirsky, "The History of Russian Literature." (Lecture III.)

At Bedford College, Regent's Park, N.W., 5.15 p.m. Mrs. H. A. L. Fisher, "The Economic Position of Married Women Under the Law."

At the London School of Medicine for Women, Hunter Street, W.C., 5 p.m. Prof. W. C. Cullis, "Respiratory Exchange." (Lecture III.)

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Miss Grace Owen, "The Present Prospect of the Nursery School."

FRIDAY, FEBRUARY 8.. London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Lieut.-Col. C. B. Levita, "Slum Areas in London."

Royal Institution, Albemarle Street, W., 9 p.m. Sir Arthur Evans, "Minoan Art of Crete."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Mr. R. W. Wilson, "Repair and Upkeep of Pneumatic Tools."

Astronomical Society, Burlington House, Piccadilly, W., 5 p.m.

Malacological Society, at the Linnean Society, Burlington House, Piccadilly, W., 8 p.m.

Aeronautical Engineers, Institution of, at the Engineers' Club, Coventry Street, W., 6.30 p.m. Mr. R. C. Chadwick, "Aeroplane Performance Estimates."

Timber Trade Lectures, London Chamber of Commerce, Oxford Court, Cannon Street, E.C., 6.30 p.m. Mr. H. A. Pritchard, "Forestry."

Physical Society, Imperial Institute of Science, South Kensington, S.W., 5 p.m. Annual General Meeting.

University of London, University College, Gower Street, W.C., 5.30 p.m. Dr. D. Heron, "Business Forecasting."

5.15 p.m. Dr. B. Hart, "Psychology and Medicine."

At King's College, Strand, W.C., 5 p.m. Dr. W. D. Lang, "Some Palæontological Evidence with regard to Evolution." (Lecture II.)

Prof. R. W. Seton-Watson, "The Rise of Nationality in the Balkans." (Lecture III.)

Photographic Society, 35, Russell Square, W.C., 7 p.m. Lantern Lecture.

SATURDAY, FEBRUARY 9.. Royal Institution, Albemarle Street, W., 3 p.m. Dr. R. S. Rait, "The Last Years of the Scottish Parliament." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,716. VOL. LXXII.

FRIDAY, FEBRUARY 8, 1924.

7 MAR 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

Wednesday, February 13th, at 8 p.m. (Ordinary Meeting.) H. Maxwell-Lefroy, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle." Sir Aston Webb, K.C.V.O., C.B., P.R.A., will preside.

Friday, February 15th, at 4.30 p.m. (Indian Section.) Sir Richard M. Dane, K.C.I.E., Commissioner, North India Salt Revenue, 1898-1907, and Inspector-General of Excise and Salt for India, 1907-09, "Salt Manufacture in India." The Rt. Hon. Lord Meston, K.C.S.I., LL.D., will preside.

EIGHTH ORDINARY MEETING.

Wednesday, January 30th, 1924; Sir Herbert Jackson, K.B.E., F.R.S., in the Chair.

The following candidate was proposed for election as a Fellow of the Society :—

Aslam, Syed Mohammad, B.A., Oxford.

The following candidates were duly elected Fellows of the Society :—

Alexander, Philip, London.
Fletcher, John Kyrle, Newport, Mon.
Graydon-Bradley, Mrs. E., London.
Margerison, William Joseph, Leeds.
Rhead, Frederick A., Wolstanton, Staffs.

A paper on "The History, Development and Commercial Uses of Fused Silica" was read by Sir Richard Arthur Surtees Paget, Bt.

The paper and discussion will be published in a subsequent number of the *Journal.*

CANTOR LECTURE.

On Monday, February 4th, 1924, Dr. Eric K. Rideal, M.B.E., B.A., D.Sc. F.I.C., of the Chemical Laboratory, The University, Cambridge, delivered the second lecture of his course on "Colloid Chemistry."

On the motion of the Chairman, Mr. Walter C. Hancock, a vote of thanks was accorded to Dr. Rideal for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

DOMINIONS AND COLONIES SECTION.

Tuesday, February 5th, 1924; Sir George R. Le Hunte, G.C.M.G., in the Chair.

A paper on "The Commercial Future of the Backward Races, with special reference to Papua" was read by Mr. F. W. Walker.

The paper and discussion will be published in a subsequent number of the *Journal.*

REPRINT OF CANTOR LECTURES.

The Cantor Lectures on "Nitrates and Ammonia from Atmospheric Nitrogen," by Mr. E. Kilburn Scott, A.M.Inst.C.E., M.I.E.E., have been reprinted from the *Journal* and the pamphlet (price 3*s.*) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2.

A full list of the lectures, which have been reprinted and are still on sale, can also be obtained on application.

BINDING COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their annual volumes of the *Journal,* cloth covers can be supplied, post free, for 2*s.* each, on application to the Secretary.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained by Fellows on application to the Secretary.

ROYAL SOCIETY OF ARTS.

◆

INDIAN SECTION.

FRIDAY, JANUARY 18TH, 1924.

SIR THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., in the Chair.

The paper read was :—

THE SURVEY OF INDIA.

BY

COL. H. L. CROSTHWAIT, C.I.E., R.E., retd.,
Formerly Superintendent, Survey of India.

It is just eight years since my former chief, Sir Thomas Holdich, delighted an audience in this theatre with an address on the "Romance of the Survey of India." I cannot hope to emulate the charming and picturesque language with which Sir Thomas habitually adorns his addresses, nor can I treat you to much "romance," for the task I have before me this afternoon is to endeavour to give you an idea of how the survey of a great country is carried out; how its maps are made; and the nature of the scientific work undertaken by the Survey of India. It will, of necessity, only be an outline of the many enterprises with which this great organisation is concerned.

Let us glance for a moment to the size and extent of the country with which we have to deal. The Indian Empire covers an area of rather more than 1,800,000 square miles. This is about fifteen times as large as Great Britain and Ireland. Nevertheless, such is the enormous size of the British Empire that it is only about one-eighth of the whole. If we superpose an outline of India on that of Europe, placing Koh-i-Malik Siah, which is the trijunction of India, Persia and Afghanistan, on the coast of Scotland, then the eastern boundary of the Empire will fall in the Caspian Sea, and, locating Cape Comerin in Greece, the northern confines of India will touch Lapland. But the work of the Survey of India does not stop at the frontiers of the Empire—for it is concerned with the mapping of the adjacent countries of Arabia, Mesopotamia, Persia, Afghanistan, Turkistan, Tibet, and a part of China, and it has mapped Somaliland in Africa.

These countries have, however, not been mapped in the same rigorous way that India has been surveyed, and, with the exception of considerable areas in Mesopotamia and Persia, which were more or less rigorously surveyed during the Great War, the external maps of India depend on hasty military surveys carried out during various campaigns, as opportunity presented itself, and for the larger part on travellers' reports and reconnaissances and from every other available source.

In fact no military expedition has been undertaken on, or beyond, the Indian frontier which has not been accompanied by surveyors. These maps are available on the millionth scale.

The Survey of India, like other great survey organisations, had its origin in the necessity for maps arising from military operations. Though there had been detached surveys during the early wars of Clive, it took a permanent shape with the appointment, in 1764, of James Rennell, who later became the celebrated geographer, as Surveyor in Bengal, and as Surveyor-General in 1767. Rennell based his work entirely on traverses, distances being chained and checked by astronomical observations. He covered with his surveys the area then in occupation of the British in India, and extended them even as far as Agra. The scale of his Bengal Atlas, published in 1779 and lately reproduced in Calcutta, is one-inch to five miles—a copy of which is on the table. Rennell retired in 1776, and in 1778 he brought out the first approximately correct map of India. D'Anville's map had already appeared in 1754, but, owing to lack of material, it had little pretensions to accuracy. But his map is certainly of historic interest as showing what was known of India at the time Rennell started work. The Royal Geographical Society possesses copies of this map.

As Rennell had been the father of Indian geography, so Colonel Lambton was the father of Indian Geodesy, and the originator, in India, of the true foundation on which topographical mapping should rest. It was not until the end of the eighteenth century that triangulation was recognised as the true basis for accurate mapping. Also, our Indian possessions had grown to such an extent that methods which were passable where comparatively small areas are concerned became inaccurate when applied to a large country. Lambton was an officer of the 33rd Regiment, and it was largely due to Sir Arthur Wellesley—at that time commanding his regiment—that he was able to put forward his scheme for the substitution of triangulation for traversing as the basis of survey operations. Lambton began work in 1802, not without opposition to the new method of triangulation as opposed to traversing, and his position was not recognised until 1818 when he was appointed the first Superintendent of the Trigonometrical Survey. He carried out the net-work triangulation in the neighbourhood of Madras shown on the index chart, Fig. 1. He died in 1823 at the age of seventy-two while at work in the field—being succeeded by his assistant, Sir George Everest. From this time onward the operations of the Survey of India have been recorded in a series of great volumes and reports which form a library in themselves.

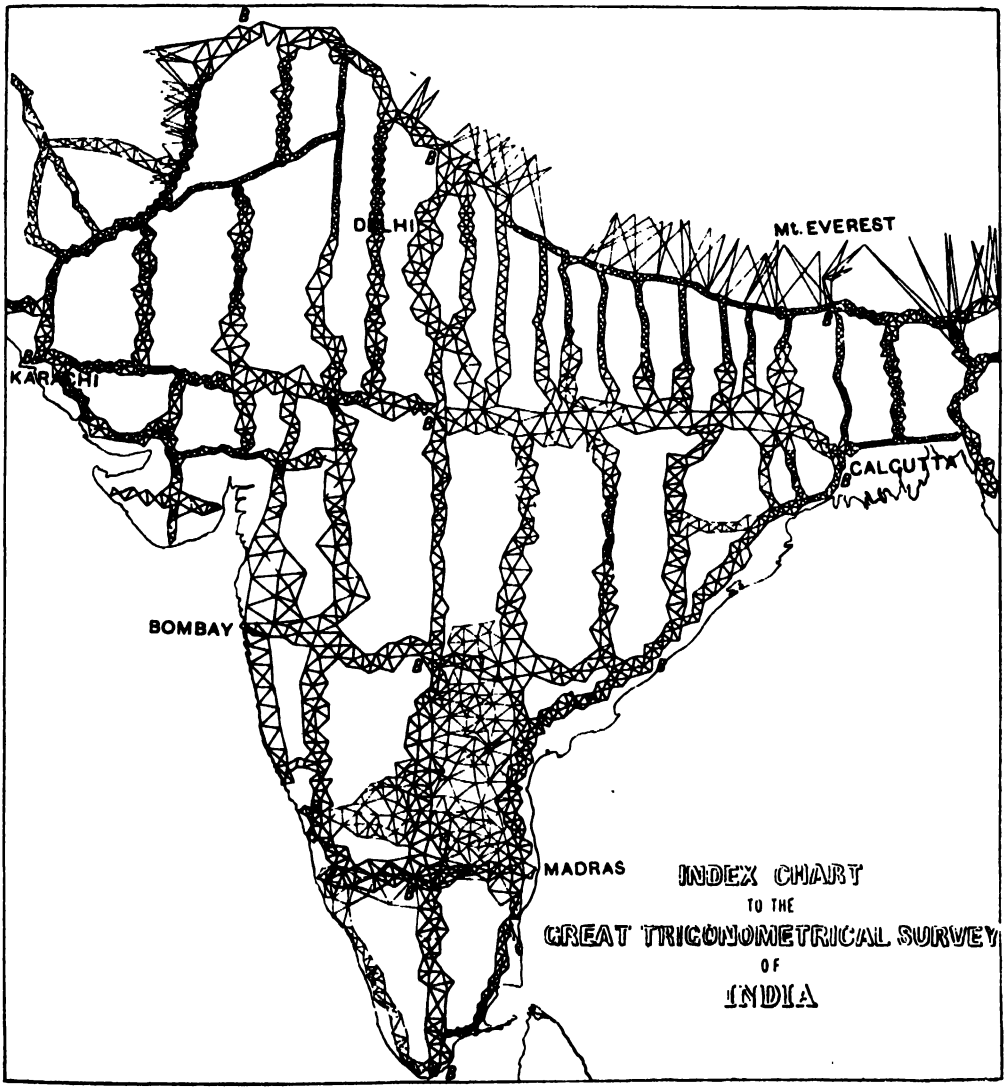

FIG. 1.

For our purpose it is convenient to divide the operations under three heads:—

1. Geodesy.
2. Topography and the drawing of the fair map.
3. The Reproduction and Printing of the map.

The Geodetic Branch which is represented by the Great Trigonometrical Survey is concerned primarily with the fundamental operations of survey, namely, the construction of the foundation for the topographical work which is to follow. This consists in the determination with the greatest possible accuracy of the latitude and longitude of a number of points, permanently fixed on the ground, by means of first-class triangulation, and, at the same time, the determination of their heights controlled by spirit-levelling of precision.

But, in another aspect, geodesy is one of the most fundamental of sciences, for it concerns itself with the measurements of arcs of the meridian which, combined with arcs measured in other countries, give the means of determining the size and shape of the earth—a knowledge of which is essential for so many different operations. Geodesy, therefore, is a science of international importance. We have here a chart of the Great Trigonometrical Survey of India as devised by Everest. Though Lambton's method of triangulation was a great advance on that of Rennell (shown in the neighbourhood of Madras), his network introduced certain technical difficulties. It was not easy to adjust those errors of observation and of instruments to which all human endeavours are susceptible, nor, indeed, was it necessary to cover the *whole* country with points fixed with such great accuracy involving an inordinate expenditure of time and money. Sir George Everest devised a system which obviated these drawbacks. To him we owe the introduction of methods far ahead of his times and geodesy remains to this day more indebted to him than almost any other person. He conceived the idea of superseding the net work triangulation by meridional and longitudinal chains of triangles to cover the country in the form of a gridiron. They followed selected meridians and parallels of latitude enclosing quadrilateral figures, so that the chains closed on themselves, thus affording a means of distributing errors which must be generated no matter how carefully the work is carried out. This system has remained in vogue to the present day. The origin of the Survey of India is at Kalianpore in Central India, near the Sironj Base. It was here that Everest established an observatory in order to fix, by astronomical observations, the position which determines the location of India on the earth's surface.

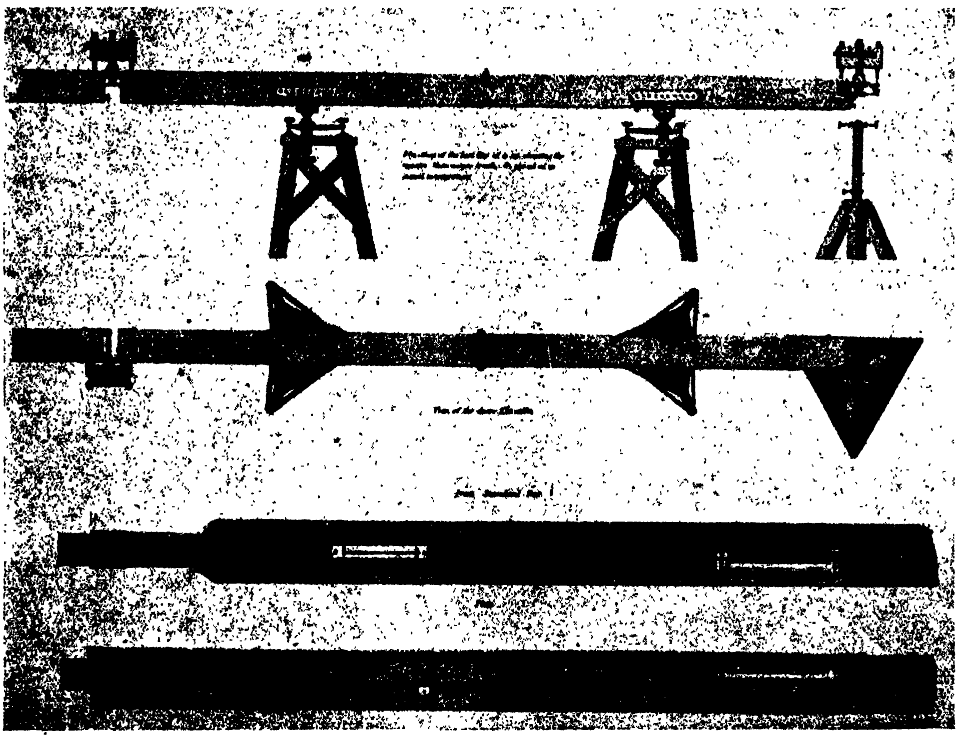

FIG. 2.—Colby Base Line Apparatus.

Where the triangles are carried across the flat plains, they are small and have short sides—it being necessary to use towers to extend the field of view of the observer. In hilly country they are, of course, as long as possible. The central spaces enclosed by the quadrilaterals are filled up by secondary and tertiary triangulation in order to provide sufficient points for the plane-table surveyors to construct the detailed maps.

This triangulation is carried out by smaller instruments and is of a lesser degree of accuracy than the geodetic work on which it is based, but, as will be seen from an inspection chart, it is never necessary to go far from the controlling points. In flat and enclosed country traversing has to be resorted to in order to provide points for the plane-tablers, but, as before, it is controlled by the primary triangulation which is never far off.

The chain of triangles extending up the centre of the chart from Cape Comorin to the Himalayas is the meridional arc known as the "Great Arc." The portion lying between Bangalore and the mountains was used by Everest for the determination of the elements of the earth. It is nearly thirteen hundred miles long and embraces 21° of latitude. The triangulation is controlled by ten bases which are marked "B" on the chart. They are distributed as equally as possible over the whole area. These bases were measured with the greatest possible accuracy by an apparatus devised by Colonel Colby, R.E. (Fig. 2.) It consists of a series of compensated bars, each ten feet long, which, supported on trestles, are placed end to end, though not actually touching each other. They are, however, made optically continuous by a pair of microscopes—so mounted as to bridge the interval between the bars, the distance apart of the microscopes being accurately known. The bars can be moved horizontally and laterally in order to obtain correct alignment by means of slow motion screws which actuate the platforms on which they rest. As the ground had to be levelled for the reception of this apparatus, and the bars were cumbersome and expensive to work with, they will never be used again, and now are only of historic interest. In future, bases will be measured with invar tapes. The existing bases are about seven miles long. Future ones, using the invar tape where level ground is not necessary and rapidity of measurement is much greater, will be considerably longer—up to fifteen or twenty miles.

FIG. 3.—Nojli Tower.

A station of the Great Trigonometrical Survey, in the plains of India, near Roorkee, from which several Himalayan peaks were observed.

The original triangulation was carried out with theodolites 36 inch and 24 inch in diameter and having five reading microscopes. The tripods on which they stood were, except in the case of rock stations, supported by specially constructed isolated masonry pillars. The modern substitute for these theodolites has a 12 inch graduated arc and three reading microscopes.

The geodetic triangulation gives extremely accurate, and, for topographical purposes, errorless, values of the latitude and longitude of the points shown on the chart. Their heights are controlled by means of spirit levelling of the highest precision which has its origin at mean sea-level determined by tidal observations. This is carried out in duplicate by independent levellers with permanent bench-marks every few miles apart, and with special standard bench-marks at important places. These bench-marks are largely made use of for irrigation and other engineering purposes.

Besides the provision of data as described, the geodetic branch undertakes a series of tidal observations with self-recording tide-gauges for the determination of tidal constants by harmonic analysis, from which are constructed the tide-tables for the use of shipping in Indian waters. Tables for forty ports are computed by the Survey of India and are issued a year in advance, showing the predicted time and height of the high and low water throughout the year. They include the ports of Suez, Bushir, and Basrah, outside India.

The trigonometrical branch has undertaken a magnetic survey of India which has recently been completed—though certain self-recording stations, registering the declination, horizontal force, and vertical force, are still maintained. A number of repeat stations are also visited every year with a view to ascertaining secular changes.

There are two allied investigations by the survey of India which are of great interest to us all, as they relate to the constitution of the earth's crust on which we have to pass our existence, namely, gravimetric observations to determine the force of gravity, and investigations into local attraction. The chief object of gravity measurements is to give an idea of the relative distribution of the density of matter on the earth's crust. An unequal distribution would mean that the general equilibrium, or balance, of the material composing the crust was upset, and, in consequence, the crust itself might be in a state of strain. As in nature there is always a tendency towards adjustment, so that to bring things back to a state of equilibrium we might expect earth movements in such regions.

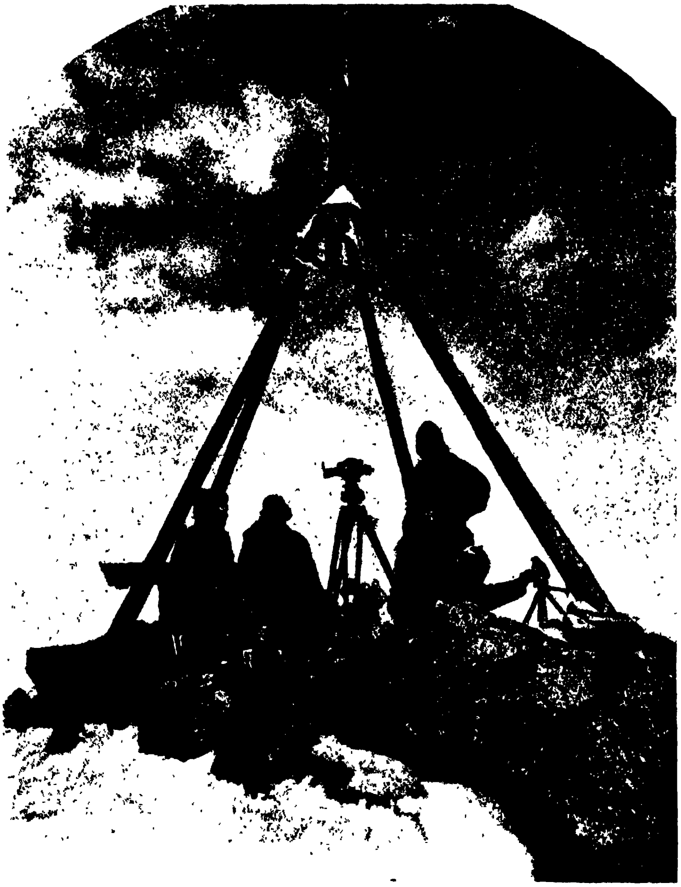

FIG. 4.—A triangulation station on the Pamirs.

More has probably been written regarding the phenomenon known as local attraction than on any other geodetic subject. Local attraction exhibits itself in the effect it has on verticality of the plumb-line especially in the neighbourhood of mountain masses; but a deflection of the plumb-line means a corresponding, apparent displacement of the zenith, and, since the declination of the zenith is equal to the latitude of the place, local attraction affects all astronomical latitudes.

The Himalayan Range, with the Tibetan Plateau lying to the north of it, forms by far the greatest topographical feature on earth. For this reason, India presents especial facilities for the study of local attraction. Surveys at the foot of the mountains show that this great mass has an enormous effect on the plumb-line. Let me try to explain how it is possible to ascertain that the plumb-line at the foot of the mountains is drawn towards them. Suppose we go south into Central India to Kalianpore—four hundred and thirty miles away from the hills and outside the attraction of the now far distant mountains—and observe an astronomical latitude there. Then we shall have, we hope, a latitude uninfluenced by local attraction. This we call our "initial latitude." Now we can ascertain an independent latitude for a point at the foot of the mountains, based on the latitude of Kalianpore, by measuring the actual distance between the two places on the earth's surface through the medium of a chain of triangles, such as you have already seen, depending on the measurement of horizontal angles which are not influenced by local attraction, for it is only vertical angles that are affected.

Latitude brought up in this way is called the geodetic latitude, as opposed to the astronomical latitude, which, as already mentioned, is dependent on the declination of the zenith. The difference between the two latitudes is the amount of local attraction. The point to be emphasised about local attraction is not that the plumb-line is deflected towards the Himalayan mass, but that it is not deflected nearly as much as the combined visible mass of the mountains and the Tibetan Plateau would appear to warrant. To take a concrete example—the deflection at Dehra Dun at the foot of the Himalayas is 31″. As one second of arc is equal to about one hundred feet on the earth's surface, this represents three thousand one hundred feet. You would be that amount out if you had to depend for your position on the astronomical latitude only, and no maps based on it would be accurate as regards location of places on the earth's surface where local attraction existed. Now, if we compute what the deflection of Dehra Dun should be, taking into account the apparent masses lying around, it works out to 86″, whereas it is really only 31″. What is the cause of this difference? Now, one of the most difficult problems the geologist and geodesist had to deal with was how the earth's crust, which has little inherent strength, can support such an enormous weight as the Tibetan Plateau—some three miles high above sea-level and several hundred miles wide. The theory of Isostasy, which the study of local attraction has

FIG. 5.—Survey station, Koh-i-Malik Siah.

called into existence, comes to the rescue, and puts forward the suggestion that mountains are, as it were, floating like icebergs in a kind of molten interior—or, to put it in another way, if they are not actually floating, they are constructed so that they would float. This is brought about on the supposition that the extra protrubarance is compensated for by a defect of density below in the roots of the mountains, and it is this point that plumb-line observations bring out. Whatever the process which was at work in the building of mountains causing great masses of enormous weight to stand up above the general level of the earth, it has also brought about a compensating deficiency below them—thereby making it possible for mountains to exist without putting the crust to any very considerable strain. Now, this so-called compensation is supposed to extend to a certain depth above which columns of equal sections. of the earth's crust have equal weights, no matter whether they emerge at the surface of the Tibetan Plateau—three miles high—or at sea-level. This is what the theory of Isostasy assumes, and observations for local attraction seem to show that compensation does exist. If the mass north of Dehra Dun were completely compensated, according to the theory, it has been computed that the deflection would be only 18″, but, as we have already seen, it is actually 31″—so that, if this theory be correct, the Himalayas (in this neighbourhood) may be said, in terms of plumb-line deflection, to be short of compensation by 13″. But this mass represents the result of the greatest convulsion the earth has ever experienced—anyhow, in its present state—so that, while there may be a tendency towards isotatic equilibrium, it may not be so far advanced in India as in other places—for instance, in the United States, where mountains are older and where this compensative action action has been longer at work. It might follow that the Tibetan mass, not being completely compensated, is not in a condition to float freely, and has, therefore, to receive a measure of support from the crust. This would have the effect of setting up strains, and may be a contributive cause to the

Fig. 6.—Surveying in Garhwal.

frequent earthquakes which occur in this mountainous region—but here we enter the realms of pure speculation.

How mountains are built up in the first instance, and how the compensation which allows them to exist came about, are, as yet, unsolved problems. The explanation which the theory of Isostasy offers may be correct, but the problem is far from simple and requires extended investigation before any conclusive results are arrived at.

It is often easier to make observations than to give them a correct interpretation. This especially applies when we attempt to unravel the hidden workings of the earth's crust. It should be mentioned that the description of local attraction here outlined has been shorn of many complications. It has been stated, with some truth, that the investigation of this problem has been more prolific in giving birth to new problems than in solving old ones. Too much space has, perhaps, been devoted to this question, but every investigation in this connection is of vast importance and interest.

We must now pass to the next division of our subject, namely, topography.

Detailed mapping in the field is carried out entirely by means of the plane-table, which is a simple instrument admirably suited for small scale work such as is carried out in India. On it, the triangulated, or traverse points, are plotted in their correct position, with their heights written in. With the help of these surveyors can fill in the topographical details, including the contours, with little or no direct measurement, by means of the method of re-section; but, plane tabling is not, by any means, a mechanical operation. It requires, to produce good results, considerable artistic skill, good draughtsmanship, and long practice, combined with an "eye for country." The plane-table work is normally carried on in the field on the one-inch scale. This is subsequently enlarged by photography to one-and-a-half-inch to one mile, and blue prints are made from the field sections on drawing paper, and on this scale the work is fair-drawn in black.

Two fair sheets are drawn—one for the details of the map, and one for the contours only. For technical reasons it is necessary to separate in the first instance the contours from the detail. The completion of these two sheets with the addition of the "colour pattern" showing the colours in which the different features appear on the printed map, ends the work of the field party. The surveying is carried on in the cold weather, and the fair drawing of the work done in the hot season, a suitable division of work in a country like India.

The third, and last, division of our subject relates to the reproduction and printing of the map in colours. The original fair sheets, when received from the field party, in the reproducing office, are photographed, and at the same time reduced by one-third, namely, in the case of the normal map to the one-inch scale, that is, back to the scale of survey. This applies both to the detail and the hill sheets. The object of the reduction is to sharpen up the line work and lettering of the map. From the negative of the detail sheet copies on glass are made by a process of contact printing. From these copies are then selected, one for each colour—red: roads and villages; blue: water forms; black: names, and so on. The example shown is one selected to serve as the red copy. Using the "colour pattern," already mentioned, as a guide, everything is painted out except those items which are to appear in red on the printed map. This process is repeated in turn on the copy selected for each colour. We now have a series of negatives each representing a different colour. From these a similar number of zinc plates are prepared by the helio-zincographic process, all of exactly the same size (since they were all made from the same original), so that, when printing takes place, each colour falls in its correct position. These plates are then inked up in the appropriate colours, and the map is printed from them, thus combining the various colours. All this time the contours have been kept apart, as it would complicate matters too much to attempt to paint them out had they not been separated in the first instance, as already described. This is the reason that a separate contour sheet is drawn. A zinc plate is now made in the same way as for the colours, and the contours are sur-printed in brown. The result is a finished map of each, some specimens of which are exhibited.

The foregoing is a mere outline of the method employed. There are, of course, many details connected with the process to which it is impossible to refer. The maps themselves afford the best evidence of the excellent work now produced by the Survey of India.

The Indian maps used for general administrative purposes are on the one-inch and half-inch scales. There is also a series on the quarter-inch scale. The maps of India and Adjacent Countries are on the millionth scale, or about one inch to sixteen miles. There is a series covering the same area but conforming to the requirements of the International Map of the World, to which the Indian Survey has contributed a large number of engraved sheets. There are many other maps which have been brought out for special purposes too numerous to refer to here.

A very complete and interesting exhibit of maps will be on view at the British Empire Exhibition next April.

In conclusion, I should like to say a few words as regards the future of scientific work in India. Even in these days of financial stringency there will probably not be much difficulty in getting funds for map making—for the reason that the necessity for maps is fully recognised, though, from motives of economy the scale of survey may suffer a reduction to a dangerous point. Let us hope that no effort will be spared to continue the world-renowned scientific work of the Survey of India the foundations of which have been so firmly laid by Everest, Walker and Burrard.

DISCUSSION.

The Chairman (Sir Thomas H. Holland), in opening the discussion, said Colonel Crosthwait's paper, like the Department which he represented, left very little scope for criticism. From the title of the paper no doubt many of the audience had anticipated references to other Surveys of India like the Marine Survey, the Botanical Survey, the Geological Survey, and the Archæological Survey, but there was really only one department which was known, and properly known, as *the* Survey of India. There were many Government Engineers, but Colonel Crosthwait and some of his colleagues would state that there was only one Corps of *Royal* Engineers. His thoughts were turned by one sentence in the paper: Colonel Crosthwait said: "It is often easier to make observations than to give them a correct interpretation." Experience showed that, on the other hand, the temptation to produce an interpretation was what many scientific men yielded to rather than the dull path of simple observation. It was not easy to make observations, and to continue doing so regardless of theoretical consequences, without any idea of what the observations might mean. It was in the cold and mechanical operation of recording observations that the Survey officer excelled. He knew that his map would not be judged by its artistic general appearance, but by critical and microscopic examination of each purely local detail—by the geologist, by the irrigation officer, by the railway engineer, and even by the tired pedestrian. He also knew that nine out of ten among those who used his map and found it useful accepted its usefulness as a matter of course, requiring neither praise nor comment, but he knew that the tenth man who found a microscopic error proclaimed the great inconvenience to which it had put him. Yet that error might be due to any one of the many who had specialised shares in the production of the map. So the Survey officer had to be not only meticulously accurate for his own sake, but he had to be silently loyal to his team. The audience were no doubt wondering what he (the Chairman) was driving at. It was this. There were two main phases of scientific operation. First, there was the making of observations, and, secondly, the theoretical speculations which followed. For the first stage, blind, rigid discipline was required of the Survey staff. For the second stage imagination and freedom from the bonds of orthodoxy might be sometimes necessary. It was, then, possible to see what had been the foundation policy which had been consistently maintained for over 150 years in staffing the Survey of India. The Survey of India had been staffed by officers who had the necessary scientific foundation but who had had drilled into them also that form of discipline which hitherto among English people had been attainable only in our fighting Services. So far as mere maps and mere records were concerned, any experienced critic would say that those products of team discipline in India compared favourably with those of the most civilised countries of the world. What about the other side? Had that faithful adherence to mechanical necessity dulled the imagination of the Survey officer? Had he neglected the purely scientific and theoretical by-products of his work? Anyone at all acquainted with the history of the Survey could point to a succession of officers who had become distinguished in the world of geographical exploration, sometimes in the world of mathematical research, and especially, in recent years, in geodetic speculation,—men like Sir George Everest, the Thuilliers, Sir Sidney Burrard, Sir Gerald Lenox-Conyngham, Colonel Ryder and Colonel Crosthwait. Coming to the Home Survey there was the same type of officer, but working under quite different conditions, for instance, Alexander Ross Clarke, who had received the Royal Medal of the Royal Society before even he had been elected a Fellow. Any geodesist, English or foreign, would as soon think of travelling without Ross Clarke's treatise as a Bishop would think of undertaking an Episcopal visitation without a prayer book. Ross Clarke's figure of the earth had remained the standard figure for all geographers, until more recent gravimetric observations had rendered necessary quite minor and local corrections. On the scientific side ideas had not always originated among Survey officers. The theory of mountain compensation had not originated with the Survey, but with Archdeacon Pratt, of Calcutta, who had speculated on the faithfully recorded and very accurate results of the Survey measurement of the great Indian arc; but it had required Survey officers, like Sir Sidney Burrard, Sir Gerald Lenox-Conyngham and Colonel Crosthwait to show that Archdeacon Pratt was not quite right. In 1889, Captain Dutton, of the United States Navy, presented Pratt's theory in a new form. He gave the idea an orthodox baptism, and a name, which seemed to be necessary always for the respectable life of any scientific theory, namely, the theory of isostasy, to which Colonel Crosthwait had referred. The Survey officers in India, however, showed that isostasy could stand unmodified only when the observations were very few, or were wanting in the precision which was customary in the Survey of India. Then G. K. Gilbert of America, a distinguished geologist, had explained the anomalies which were observed by pointing out, in 1913, that whilst each column of the earth's crust might be in isostatic equilibrium with all the others, the mass might be unevenly distributed vertically, so that the plumb-line and pendulum would be affected differently by columns of exactly the same total weight in different areas. The credit for that ingenious suggestion had been given to G. K. Gilbert all the world over, but if one read one of the professional papers of the Survey of India, No. 13 of 1912—one year before G. K. Gilbert published his paper—one would find the following remark—which was only given parenthetically as if it was a sort of passing thought: "Assuming the doctrine of isostasy to hold, is it not possible that in any two columns of matter extending from the surface down to the depth of compensation there may be the same mass, and yet the density may be very differently distributed in the two columns? These two columns, though in isostatic equilibrium, would act differently on the plumb-line owing to the unequal distribution of mass. The drawback to treating this subject by hard-and-fast mathematical formulae is that we are introducing into a discussion on the constitution of the earth's crust a uniform method when, in reality, probably no uniformity exists." That had been published without any fuss in India one year before G. K. Gilbert's theory, which had attracted so much attention, was published in America. He thought it was fair to call attention to it because the Gilbert Theory was so continuously quoted in geological literature. He might also tell the audience that the author of Professional Paper No. 13, in 1912, was Colonel H. L. Crosthwait. He did not think it would be difficult to show that organisation and the execution of observational work, which formed nine-tenths of all Survey work, and which was the outcome of a rigid discipline, had not inhibited the scientific imagination of its officers. They had taken their line of conduct from the first great Surveyor-General, Major James Rennell, who, with one European and one Armenian, had produced the first reliable map of Bengal, and who, at the mature age of 23, with four European officers, had been entrusted with the duty of undertaking the larger task of a general Survey of Northern India.

He had brought with him a very interesting document, which was a reproduction of James Rennell's Journals—the Journals he took with him when he retired from India. They had been sent out by Sir Rennell Rodd, who was then Ambassador at Rome, and who was a great grandson of Sir James Rennell, to the Victoria Memorial. When they had come into his own hands as a Trustee of the Memorial, he had thought them of sufficient interest to have them carefully edited and published as a separate memoir by the Asiatic Society of Bengal. He thought that memoir, which had been very faithfully edited by Mr. La Touche, of the Geological Society, was a most interesting document indeed. He would read one section in which he was sure the audience would be interested:

"Letter to the Court of Directors, March 30, 1767." (It was an apology for having to pay a very large salary to the new Surveyor-General)—"So much depends upon accurate surveys both in military operations and in coming at a true knowledge of the value of your possessions, that we have employed everybody on this service who could be spared and were capable of it. But as the work must ever be imperfect while it is in separate and unconnected plans, we have appointed Captain Rennell, a young man of distinguished merit in this branch, Surveyor-General, and directed him to form one general chart from those already made and such as are now on hand as they can be collected in. This, though attended with great labour, does not prevent his prosecuting his own surveys, the fatigue of which, with the desperate wounds he has lately received in one of them, have already left him but a shattered constitution. This consideration, and his being deprived of every means of advantage while he is thus continually moving up and down a country unexplored by Europeans to the utmost risk of his life, we hope will justify us for increasing his salary to 300 rupees a month, which indeed may be considered as only a just reward for his past services and sufferings." Then followed the ancient policy: "We beg leave to recommend it as a measure well worth your attention, the keeping your Corps of Engineers constantly supplied with young gentlemen properly instructed in that particular branch." Rennell retired in 1776, a broken man, desperately wounded in a riot, and suffering continually from fever. The Journal made one almost tired to read—telling of the man setting off in a boat on the 7th May in order to make a survey of the Ganges River at a time of the year when most Survey Officers should be returning for recess—out through the monsoon as well as the hot weather and cold; never in the hills and never home on leave. There was a piteous letter which he wrote, asking at the end of 13 years' service, that he might be allowed to retire from the Service on a sufficient pension. He was allowed to retire, and he enjoyed that pension for 54 years! Rennell, the faithful surveyor in the field, and a brilliant scientific geographer in retirement, was the example and the type which had been faithfully followed—the type that had made the Survey of India pre-eminent among the Surveys of the world.

MR. A. R. HINKS, C.B.E., M.A., F.R.S., Secretary of the Royal Geographical Society, congratulated Colonel Crosthwait upon a very clear and useful statement of the operations of the Survey of India which would be difficult perhaps to find elsewhere and which geographers would particularly welcome when it was published in the Society's *Journal*. The author, being a modest member of that great Service, had not perhaps laid sufficient stress upon two or three points which stood out as the great contributions of the Survey of India to geodesy. India had been for a long time the only part of the British Empire which had made any substantial contribution to the figure of the earth. The contribution from the British Isles had not been a sufficiently large arc to be of much importance, and until the late Sir David Gill measured part of the Great Arc of the 30th meridian in Africa, the contributions of the latitudinal and longitudinal arcs of India had been the only contribution of the Empire to a great problem which interested the whole world. Although the author had made some mention of the investigations of the deviations of gravity, he (the speaker) thought perhaps he had not laid so much stress upon it as that it was evident to the audience that the whole of that fascinating subject was due to the Survey of India in its origin and also in many of its developments. It was quite true that Americans had made great play with the subject since. No one would wish to decry the great merit of the contributions made by Hayford and Bowie, but in the first instance it had been the work of the Survey of India which, with the mathematical assistance of Archdeacon Pratt, had first called attention to the most important fact that the mountains in the Tibetan Plateau did not influence the plumb-line nearly as much as would be expected. Again, it had been that eminent contribution of Sir Sidney Burrard, and, later, the papers of Colonel Crosthwait and other officers, which had thrown so much penetrating light and valuable criticism upon the somewhat artificial assumptions on the subject which had been made by Hayford. Those were eminent contributions of the Survey of India to the stock of great scientific problems of the world, and he thought all present would wish that particular mention should be made of them. They could congratulate Colonel Crosthwait upon having read such an interesting paper, though he had strictly avoided the romance with which Sir Thomas Holdich had treated the subject in his paper read before the Society some years ago. There were two or three picturesque incidents connected with the Survey of India which he would like to mention. There were some well-known tables of logarithms calculated by Shortrede, and in the introduction it was stated that those tables had been calculated "in the sublime solitudes of the Western Ghats." One Royal Engineer had asked him: "Do you know why these tables were calculated in the sublime heights of the Western Ghats? Why was Shortrede there at all?" He had replied that he did not know, and the answer had been: "Because he dropped an 18-inch theodolite off the top of one of those towers." He would like to know if there was any truth in that incident. Then again, there was the romantic episode of the discovery of Mount Everest, which had not happened in the field at all, but in the Survey offices in Calcutta. It must have been a great moment when they had found a mountain, 29 thousand feet high, sticking up in the Survey offices in Calcutta, because no one would judge from looking at the mountain that it was necessarily any higher than some of its surrounding peaks. It was amusing to think how their particularly ardent friend, Sven Hedin, made capital out of the fact that the native name of Mount Everest was found upon the maps of D'Anville, and how he had been at great pains to explain to the public of Sweden that Mount Everest had been discovered by a Jesuit missionary more than 200 years ago, and that its discovery did not lie to the credit of the Protestant English. With regard to policy, the Survey of India was faced with the problem of ten thousand permanently snow-capped peaks lying along the northern frontier. They had to map those peaks, and provide them, as far as possible, with some means of reference. It seemed to him personally that it was the most interesting problem geographically that lay before the Survey, to provide a more interesting method of reference than that which was at present used. The Survey had successfully attached the name of the most eminent of their officers, Sir George Everest, to a mountain, but the trouble it had got into over that little matter had made successive Surveyor-Generals resolve that never again would another officer's name, however eminent, be attached to a mountain. But there the Survey had ten thousand peaks, each of them worthy of a name, and at present no one had thought of a better method of naming them than to call them something like:—"Peak 73 21D," which no one could call convenient in helping one to remember where it was, and which entirely and absolutely forbade any poetical description of the scenery.

COLONEL SIR GERALD LENOX-CONYNGHAM, F.R.S., said the scientific work of the Survey of India had had to be interrupted when the war broke out, and, so far as he knew, it had not been since resumed. He was not certain whether some small beginning had not been made during the present winter, but he would like to take the opportunity of saying how important he thought it was that that work should be resumed and carried on. The theory of isostasy owed its origin to the work in India; first of all to Archdeacon Pratt's calculations, and the observations which showed that those calculations could not explain actual facts, and then, in 1901, to Sir Sidney Burrard's Professional Paper No. 5 of the Survey of India, in which he showed that deflections of the plumb-line were arranged systematically, and that the zones of deflections of a particular character lay parallel to the Himalayas in such a way that it was impossible to doubt that the mountains and the deflections were both due to some common cause. It had been that paper of Sir Sidney Burrard's which had attracted the attention of Mr. Hayford to the subject of mountain attraction and he, utilising the previous work of Dutton and his idea of isostasy, put the theory into a workable form so that it could be actually used for computing attractions. Using his theory, the United States Coast and Geodetic Survey showed that the deflections of the plumb-line in the United States could be accounted for more perfectly than one would have expected. Mr. Hayford had then boldly asserted that the theory of isostasy had been proved and that isostatic compensation did exist. Then the Survey of India took up that theory and, chiefly through Colonel Crosthwait's own exertions, it was applied to the deflections there, and it was found that the calculated deflections did not agree with the observed deflections nearly so well as had been the case in the United States. When a theory was put forward and was tested, if it was found to account perfectly for all known phenomena, then it might be said that the question was settled; the theory was perfect, and there was nothing more to be done; but no one could possibly suppose that the Hayford hypothesis of isostatic compensation was the last word on the subject. It was obviously an approximation to what might be the actual state of things. So what was required was to find those areas in which the computations did not apply, and then examine more carefully what was the state of things there, in the hope of arriving at a more full knowledge of the truth than that first approximation which Hayford's theory gave. As the lecturer had mentioned, the results of computation in India did not bear out the theory of isostasy nearly so well as those in the United States. The residual anomalies were, in the Himalayan area, large. The average difference between a computed and an observed deflection in the Himalayan area was 16 seconds, which was a very large quantity. Therefore it seemed of very great importance for the advancement of science that the research into deflections and gravity phenomena in general should be followed up. There was no place so well adapted for that research as the area in and around the Himalayas, both at the base and on the outer ridges, and also further into the Himalayas themselves. The Himalayan region was the most favourably situated region in the whole world for further research into isostatic compensation.

Sir John O. Miller, K.C.S.I., said the Survey of India was more than a trigonometrical survey, and he would like the lecturer to give a little more information on some points. The scientific work of Survey in India had been from the very beginning admirably done, and it had led in recent years to officers such as Sir Sidney Burrard gaining European reputations. The topographical work of the Survey had not been equally fortunate. A great deal of topographical work had been done 60 or 70 years ago in the time of General Thuillier and others, but since then it had not been pushed on in the same way. There was apparently no pressure then for general maps of the country on a continuous plan; either that was the case, or no person of sufficient eminence came to the front to insist on the topographical work being done. The hopeless condition of the topographical maps had been brought forward very strongly by Colonel Gore when he was Surveyor-General, and India really owed a debt of gratitude to him for having come forward to state that the maps would not do. Colonel Gore put the facts before Lord Curzon, who entered with great zest into the matter. He (Sir John Miller) had been on a Committee which had gone round the country to look into the question, and they had had the great advantage of the advice and assistance of Sir John Farquharson, who was Surveyor-General in this country when the revision of the Ordnance maps was carried through. He desired to pay a tribute to Sir John Farquharson, who had been the first to draw up a definite plan of topography for India. He would like to ask the lecturer how far that plan had been carried out, or how much of India had been mapped, and the maps placed before the public; also whether the general map of India was on the 1-inch or ½-inch scale. There had been great discussions in his time as to whether the general map of India should be on the 1-inch or ½-inch scale, and 1-inch had been decided upon. Sir John Farquharson had raised the question of publishing ½-inch maps. Personally he now thought it would have been wise if ½-inch maps had been adopted for ordinary use and 1-inch maps for special purposes. He expressed the hope that the Government of India would take a liberal view of the necessity for carrying out the programme for the systematic mapping of India. There could not be the slightest doubt that the demand for general maps there would be much greater in the future than it had ever been in the past. No civilised country could preserve its self-respect and be without some general map which the traveller or engineer or soldier could use, and India had not a map of that description at present. He hoped there would not be retrenchment in the future in the Survey Department as had too often been the case in the past. If the Department was given a chance he was sure it would earn as great a reputation in the topographical and reproducing field as it had in the scientific branch. He begged to propose a hearty vote of thanks to Colonel Crosthwait for his interesting and valuable paper.

Sir Lionel M. Jacob, K.C.S.I., in seconding the motion, thought the author had no reason whatever to apologise for his paper in comparison with that which had been read by Sir Thomas Holdich eight years ago. He had himself a very clear and pleasant recollection of Sir Thomas's delightful paper, but he would like to say that he had enjoyed himself quite as much on the present occasion, and had received perhaps more instruction.

COLONEL SIR CHARLES E. YATE, Bt., C.S.I., C.M.G., M.P., said he was not a surveyor and could not speak on all the scientific matters which had been raised that afternoon. He had, however, been thrown a good deal in the way of Survey officers in India. He had served with Sir Thomas Holdich, Colonel Gore and Colonel Talbot in all their survey operations, right round Afghanistan from Quetta to Kandahar, Kandahar to Herat, Herat to Balleh, Balleh to Kabul, and he had also been at Koh-i-Malik Siah in Seistan, the picture of which had been shewn on the screen, and no one had greater admiration for the work of the Survey of India than he himself had. There was one outstanding feature of the work of the officers of the Royal Engineers who belonged to the Survey of India, namely, how well and how thoroughly they had succeeded in training Indians to be scientific surveyors. These Indians with their plane tables and theodolites, had been able to accommodate themselves to survey work and exploration, and all the hardships attendant thereto, in a remarkable manner. Many of them had done most hazardous service by themselves without any Royal Engineer officer to supervise them, so much so that when he was on the Council of the Royal Geographical Society several of those Indians received special rewards from that Society. He joined with previous speakers in hoping that the present craze for economy, by eliminating British officers from all Departments on the part of the Legislative Councils in India, would not have the result of unduly restricting the further work of the Survey in India.

The motion was carried unanimously.

COLONEL CROSTHWAIT, in reply, said that Sir John Miller, having presided over the Survey Committee which had enunciated and arranged in 1905 the Programme of the new system of mapping in India, knew more about the subject than himself. Sir John Miller had asked several questions. One was, to what extent that programme had been carried out? The scale of Survey in the field, as suggested by the Committee to which he had just referred, had been 2 inches to the mile. That had very soon been dropped for financial reasons, and the scale was now 1-inch in the field for British territory, ½-inch for Native States, and ¼-inch for desert areas. That was a very dangerous change to his mind, and should never have been adopted, and was to be deplored from the point of view of providing the country with the best maps, in fact, it was dangerous from every point of view. The military people were crying out for maps on larger scales, but in India the scale was getting smaller and smaller as time went on. In the last report he had seen, of 1,800,000 square miles, about 600,000 had been surveyed and mapped.

The meeting then terminated.

OBITUARY.

GEORGE WILLIAM TAYLOR.—The Society has lost a Fellow of forty four years' standing by the death of Mr. George William Taylor, which took place on December 27th last.

Mr. Taylor was for fifty nine years connected with the firm of Messrs. Tuck and Company, steam packing manufacturers. For thirty nine years he was managing director and secretary, and for the last five years secretary only. The early days of his connection with this company brought him into close touch with Mr. J. H. Tuck, the American inventor of Tuck's patent packing, which was the first recognised type of engine packing.

Apart from his business, Mr. Taylor's interests were unusually varied and numerous. He was a very keen mason, having attained the rank of 30th degree. He was a practical engineer, electrician, carpenter, plumber, turner (he was a member of the Turners' Company and incidentally a Freeman of the City of London), a painter in oil and water colours, and he was also a musician, being a proficient player of the piano, organ and cello; and during the latter years of his life he was keenly interested in wireless telegraphy.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 13.—H. MAXWELL-LEFROY, M.A., Professor of Entomology, Imperial College of Science and Technology, "The Preservation of Timber from the Death Watch Beetle." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., will preside.

FEBRUARY 20.—PERCIVAL JAMES BURGESS, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber." SIR STANLEY BOIS, late Chairman of the Ceylon Chamber of Commerce, will preside.

FEBRUARY 27.—CHARLES S. MYERS, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation." SIR ROBERT BLAIR, LL.D., Education Officer, London County Council, will preside.

March 5.—Major-General Sir Fabian Ware, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

March 12.—Alan A. Campbell Swinton, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.) **Sir Dugald Clerk**, K.B.E., D.Sc., F.R.S., will preside.

March 19.—R. L. Robinson, Member of the Forestry Commission, "The Forests and Timber Supply of North America." **Lord Lovat**, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., will preside.

March 26.—Neal Green, "The Fishing Industry and its By-Products."

April 2.—Sir Lynden Macassey, K.B.E., "London Traffic."

April 9.—Frank Hope-Jones, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." **Professor C. Vernon Boys**, F.R.S., will preside.

April 30.—Brigadier-General Sir Henry Maybury, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "Roads."

May 7.—J. Robinson, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

Dates to be hereafter announced:—

T. Thorne Baker, "Photography in Industry, Science and Medicine."

Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons at 4.30 o'clock:—

February 15.—Sir Richard M. Dane, K.C.I.E., Commissioner, North India Salt Revenue, 1898-1907, and Inspector-General of Excise and Salt for India, 1907-09, "Salt Manufacture in India." **The Rt. Hon. Lord Meston**, K.C.S.I., LL.D., will preside.

May 2.—Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced:—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons at 4.30 o'clock:—

March 4.—The Hon. T. G. Cochrane, D.S.O., "Empire Oil: The Progress of Sarawak." **The Rt. Hon. Lord Bearsted** will preside.

May 27.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

CANTOR LECTURES.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

Syllabus.

Lecture I.—February 25.—The carbonisation of coal considered as a process for distributing the thermal energy of the coal into therms in the form of gas, tar and coke. Factors which cause wastage of therms in the form of gas and the principles underlying high yields of gaseous therms.

Lecture II.—March 3.—The inter-relation of therms in the form of gas and tar and the process conditions which affect their distribution. Further principles underlying high yields of gaseous therms. The chemistry and economics of tar cracking.

Lecture III.—March 10.—The trend of developments in carbonising processes. The de-ashing of coal and other factors tending to increase the value of the therm in the form of coke.

COBB LECTURES.

Monday evenings, at 8 o'clock:—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, February 11..Geographical Society, 135, New Bond Street, W., 8.30 p.m. Mr. L. S. Fortescue, "Persian Azerbaijan and the Western Elburz."

Surveyor's Institution, 12, Great George Street, S.W., 8 p.m.

Metals, Institute of (Scottish Section), 39, Elmbank Crescent, Glasgow, 7.30 p.m. Mr. R. Hay, "The Properties of some Non-Ferrous Alloys."

University of London, University College, Gower Street, W.C., 5.15 p.m. Dr. A. S. Parkes, "The Mammalian Sex-Ratio." (Lecture III.).

At King's College, Strand, W.C., 5.30 p.m. Rev. C. F. Rogers, "Ecclesiastical Music." (Lecture II.).

6 p.m. Mon. R. Nathan, "Henri Becque et Georges de Porto-Riche."

5.30 p.m. Dr. R. W. Seton-Watson, "A Survey of Bohemian History." (Lecture II.).

Brewing, Institute of (London Section), at the Engineer's Club, 39, Coventry Street, W., 7.30 p.m. Messrs. H. L. Hind and S. Myer, "The Value of Hops from the Technical and Economic Standpoints."

TUESDAY, FEBRUARY 12..Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. C. H. McCarthy-Jones, "Electricity applied to the Winning of Crude Petroleum with special reference to the Yenangyoung Field, Burma."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Hon. H. P. Colebatch, "Western Australia."

Asiatic Society, 74, Grosvenor Street, W., 4.30 p.m. Mr. G. Brown, "Pictures of Burma."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. J. Barcroft, "The Respiratory Pigments in Animal Life." (Lecture I.).

Photographic Society, 35, Russell Square, W.C., 7 p.m. Dr. C. E. K. Mees, "Research."

Mechanical Engineers, Institution of (Glasgow Branch), Royal Technical College, Glasgow, 7.30 p.m. Prof. S. P. Smith, "The Electrification of Railways in Foreign Countries."

Welding Engineers, Institution of, at the Institute of Marine Engineers, 85, The Minories, Tower Hill, E., 7 p.m. Mr. J. R. Booer, "Some Chemical Aspects of Welding."

Metals, Institute of (Local Branch), Chamber of Commerce, New Street, Birmingham, 7 p.m. Discussion on "Waste Products and Losses in the Non-Ferrous Metal Industry."

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. J. H. Helweg, "Modern Danish Lyrics, 1870-1920." (Lecture II.).

5.30 p.m. Mr. N. H. Baynes, "The Roman Empire and its Invaders." (Lecture II.).

8 p.m. Miss E. J. Davis, "The City Churches and their Endowments." (Lecture II.).

5.30 p.m. Sir Bernard Pares, "Russia before Peter the Great to 1861." (Lecture IV.).

5.30 p.m. Dr. H. W. Carr, "The Transition to the Relativist Conception of Nature." (Lecture II.).

5 p.m. Prof. F. C. Burkitt, "Christian Beginnings." (Lecture II.).

WEDNESDAY, FEBRUARY 13..British Decorators, Institute of, Sheffield, 7.30 p.m. Mr. Z. Carr, "A Few Impressions of Colour and Decoration by an Architect."

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m.

Metals, Institute of (Local Section), Armstrong College, Newcastle-on-Tyne, 7.30 p.m. Mr. A. Logan, "Propellor Brass."

Mechanical Engineers, Institution of (Local Branch), Council Chamber, Birmingham, 7.30 p.m. Discussion on "The Relative Advantages of Transport by Road and Rail, with special reference to the Future."

University College, Gower Street, W.C., 5.30 p.m. Prof. Geyl, "English Diplomacy in Holland in the XVIIIth Century." (Lecture I). 5.30 p.m. Mr. I. C. Grøntahl, "Contemporary Norwegian Literature." (Lecture II.).

5.30 p.m. Mr. S. Gibson, "Oxford Libraries."

6 p.m. Prof. K. Pearson, "The Current Work of the Biometric and Eugenics Laboratories." (Lecture I.).

THURSDAY, FEBRUARY 14..Pottery and Glass Trades' Benevolent Institution, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.45 p.m. Mr. L. King, "Decoration of Table and Fancy Glass Ware."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. Sir W. Bragg, "Crystalline Structure of Organic Substances." (Lecture II.).

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Central Asian Society, at the Royal United Service Institution, Whitehall, S.W., 5 p.m. Mr. L. S. Fortescue, "The Caspian Provinces of Persia."

Historical Society, 22, Russell Square, W.C., 5 p.m. Annual Meeting. Address by President Dr. the Hon. J. W. Fortescue.

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. (Joint meeting with the Physical Society). Discussion on Loud-Speakers for Wireless and other Purposes."

Economics and Political Sciences, London School of, Houghton Street, Aldwych, W.C., 5 p.m. Sir H. L. Smith, "The Economic Laws of Art Production." (Lecture V.).

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Metals, Institute of, at the Institute of Marine Engineers, 85, Minories, E., 8 p.m. Mr. W. B. Clarke, "Metals for Lamp Manufacture."

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. I. Bjórkhagen, "Modern Swedish Prose Authors." (Lecture II.).

5.15 p.m. Prof. J. E. G. de Montmorency, "Comparative Customary Law of Europe and Asia." (Lecture IV.).

8 p.m. Prof. H. E. Butler, "Roman Private Life." (Lecture IV,).

At King's College, Strand, W.C., 5,30 p.m. Dr. E. W. Scripture, "What the Voice looks like." (Lecture I.).

5.30 p.m. Prince D. S. Mucky, "The History of Russian Literature. (Lecture IV.).

At the London School of Medicine for Women, Hunter Street, W.C., 5 p.m. Prof. W. C. Cullis, "Respiratory Exchanges." (Lecture IV.).

FRIDAY, FEBRUARY 15..Royal Institution, Albemarle Street, W., 9 p.m. Dr. J. H. Jeans, "The Origin of the Solar System."

Medical Officers of Health, Society of, 1, Upper Montague Street, W.C., 5 p.m. Prof. G. Dreyer, "Some Principles underlying Bacteriological Immunity and Vaccine Therapy."

Metals, Institute of (Local Section), at the Albany Hotel, Fargate, Sheffield, 7.45 p.m. Joint Meeting with Institute of British Foundrymen.

(Local Section), at University College, Singleton Park, Swansea, 7.15 p.m. Prof. C. H. Desch, "Fatigue and the Elastic Limit."

Mechanical Engineers, Institution of, Storey's Gate, S.W., 7 p.m. (Informal Meeting.) Mr. A. E. L. Chorlton, "The Possibility of Internal Combustion Locomotives."

University of London, University College, Gower Street, W.C., 5 p.m. Prof. J. Robertson, "The Influence of Improved Town Planning and Housing in Public Health." (Lecture III.).

At King's College, Strand, W.C., 5.30 p.m. Dr. H. Lamb, "The Internal Constitution of the Earth." (Lecture I.).

5.30 p.m. Prof. R. W. Seton-Watson, "The Rise of Nationality in the Balkans." (Lecture IV.).

SATURDAY, FEBRUARY. 16..Royal Institution, Albemarle Street, W., 3 p.m. Dr. R. S. Rait, "The Last Years of the Scottish Parliament." (Lecture II.).

London County Council, Horniman Museum, Forest Hill, S.E., 3.30 p.m. Miss C. A. Raisin, "Glaciers and Ice Work of the Past."

Journal of the Royal Society of Arts.

No. 3,717 VOL. LXXII.

FRIDAY, FEBRUARY 15, 1924.

10 MAR 1924

All communications for the Society should be addressed to the Secretary, John [illegible] *Adelphi, W.C.2)*

FUND FOR PURCHASING AND RENOVATING THE SOCIETY'S HOUSE.

Nine lists of subscriptions to this fund have been published from time to time in the *Journal*;* and a desire has been expressed by a number of Fellows that a complete list giving all the contributions up to the present date should be issued.

It will be seen that the amount received is now £42,803 17s. 5d. The cost of the freehold and legal expenses was £42,560, while the renovations, architect's fees, and furniture for the library accounted for a further £8,450. It is, therefore, still necessary to raise over £8,000, and the Council are exceedingly anxious to see this reduced as rapidly as possible. They desire to take this opportunity of thanking those Fellows who have already subscribed to the Fund—many of them with great generosity; and they earnestly appeal to those whose names have not yet appeared on the subscription lists to assist them in paying off the debt.

LIST OF SUBSCRIPTIONS.

NOTICES.

NEXT WEEK.

WEDNESDAY, FEBRUARY 20th, at 8 p.m. (Ordinary Meeting.) PERCIVAL JAMES BURGESS, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber." SIR STANLEY BOIS, President, Ceylon Association in London, will preside.

Further particulars of the Society's Meetings will be found at the end of this number.

INDIAN SECTION.

A meeting of the Indian Section Committee was held on Monday, February 4th. Present: Sir Edward A. Gait, K.C.S.I., C.I.E., Ph.D., in the chair; Sir George S. Barnes, K.C.B., K.C.S.I., Sir Thomas J. Bennett, C.I.E., Mr. Laurence Currie, M.A., J.P., Sir William Duke, G.C.I.E., K.C.S.I., Sir Thomas H. Holland, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., Major-General Beresford Lovett, C.B., C.S.I., Major H. Blake Taylor, C.B.E., and Colonel Sir Charles E. Yate, Bt., C.S.I., C.M.G., M.P., with Mr. S. Digby, C.I.E., Secretary of the Indian and Dominions and Colonies Sections.

NINTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 6th, 1924; LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

The following candidates were proposed for election as Fellows of the Society:

Elston, Frederic, London.
Mant, Sir Reginald Arthur, K.C.I.E., C.S.I., London.
Smith, Frederick Richard, Hampden-in-Arden.
Young, Brig.-General Henry Alfred, C.I.E., C.B.E., Exmouth.

The following candidates were duly elected Fellows of the Society:-

Bailey, Charles Henry, Chepstow, Mon.
Chamberlain, Clark W., A.B., Ph.D., Granville, Ohio, U.S.A.
Charawanamuttu, V. Edward, A.C.P., Kotahena, Colombo, Ceylon.
Cutner, Mrs. Frances Maud Mayfield, London.
Davis, Cecil, London.
Edwards, Kenneth C., Chester.
Evans, Samuel, Johannesburg, S. Africa.
Fuge, Captain William Valentine Greatraks, Cairo, Egypt.
Graham, Archibald, Oxford.
Gray, Arthur Wellington, Ph.D., Delaware, U.S.A.
Gray, Major-General William du Gard, C.B., J.P., Dulverton, Somerset.
Hooker, Dr. Samuel Cox, Brooklyn, New York, U.S.A.
Jones, Arthur Cadbury, London.
Khadir Meera Sahib, S.K.I., Salem, India.
Kimbell, Alfred Edward, London.
Klein, Millard A., Ph.D., Stockton, California, U.S.A.
McGregor, Dr. Robert, Michigan, U.S.A.
McLaughlin, Professor George D., Cincinnati, Ohio, U.S.A.
Matthews, William Cooper, Stafford.
Morley, Henry Thomas, Reading.
Morrison, Francis, B.Sc., London.
Morse, Charles, K.C., D.C.L., Ottawa, Canada.
Plummer, Professor Henry Stanley, M.D., Minnesota, U.S.A.
Pullen, Hugh C. G., Rio de Janeiro, S. America.
Ramsay, Dr. William Miller, Nausori, Fiji.
Rose, Joseph William, Bath.
Rose, Mrs. Ruth Starr, Maryland, U.S.A.
Rosenberg, Charles Conrad Constantine, M.D., Oregon, U.S.A.
Sahni, D. C., M.A., Patiala, India.
Spencer, Walter T., London.
Tatham, Francis John, London.
Townson, Rev. C. H., M.A., Warminster.
Ward, Sir Thomas Robert John, C.I.E., M.V.O., London.

A paper on "The Earthquake and the Work of Reconstruction in Japan" was read by MR. IYEMASA TOKUGAWA, First Secretary to the Japanese Embassy.

The paper, which was illustrated by cinematograph films, will be published in a subsequent number of the *Journal*.

COMPETITION OF INDUSTRIAL DESIGNS.

Particulars of the Competition of Industrial Designs to be held at the Victoria and Albert Museum in June, 1924, can now be obtained on application to the Secretary, Royal Society of Arts. Over £1,000 will be offered in Travelling Scholarships and Money Prizes in the various sections, and the Society's Diploma will be conferred on any candidate whose work reaches a very high standard of artistic ability and shows practical knowledge of the materials and processes of his trade.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

WEDNESDAY, JANUARY 23RD, 1924.

MR. G. E. BROWN, F.I.C., Editor of the *British Journal of Photography*, in the Chair.

THE CHAIRMAN said that it was hardly necessary for him to introduce Mr. Albert Smith, because a great many people must be familiar with his invention of the Kinemacolor process of colour cinematography, which was first demonstrated in the Society's Rooms 14 or 15 years ago. The Kinemacolor process was the first commercially successful process of colour cinematography. It had its limitations, but it delighted a large section of the public for a good many years. That evening Mr. Smith was about to show a further development of colour cinematography which he had worked out. He did not think that Mr. Smith even

yet regarded this as the final process by any means, but he would be able to show the kind of results he had secured up to now.

The paper read was :—

CINEMATOGRAPHY IN NATURAL COLOURS.

FURTHER DEVELOPMENTS.

By G. ALBERT SMITH.

In December, 1908, it was my privilege to address this Society on the subject of colour photography, and to exhibit a series of cinematograph pictures—the first of such pictures taken in natural colours. On that occasion I went somewhat fully into the theories of light and colour involved in such questions, and I also described the main principles of the cinematograph.

On the present occasion it is unnecessary to go over all that ground again (especially as I have a long programme of pictures), because what I said was fully recorded in the *Journal* of the Society (No. 2925, Vol. LVII., Dec. 11th, 1908); and also because the fundamentals of colour photography, and of the cinematograph, are now more generally understood. For instance, I think everyone now knows that the explanation of the cinematograph is simply that successive snap-shots are taken on a moving band of film at the rate of 16 per second, and that these snapshots are then exhibited one after the other at such a speed (again 16 per second) that by what is known as persistence of vision the successive pictures combine on the retina and give us the illusion of movement. If the pictures are taken at a slower rate of speed, we get the impression of jerky and hurried movements. If they are taken at a higher rate of speed—say 40 per second—we get an impression of slow and dragged-out movement.

Turning to *Colour*, it is well-known that the superimposition on paper of three correctly chosen colour records will give a picture approximating to the colours of nature; and the same results can be attained by the superimposition of three beams of coloured light passing through lantern slides to a white screen in a darkened room. The "three-colour theory" first promulgated by Thomas Young, early in the last century familiarised us with these facts, and all processes of colour photography and colour printing are based upon it.

In my last paper and demonstration in this room, I discussed the application of this "three-colour theory" to the art of the cinematograph, and described careful and thorough tests made as far back as 1902, which resulted at that date in failure. The failure was mainly due to the fact that we employed *three lenses*, placed as closely together as possible, but which necessarily took three pictures very slightly *differing* from one another. These slight differences became aggressive when the pictures were superimposed, for they produced coloured margins where overlapping occurred.

It was next found that it was practicable to reduce the three colours to *two only*, and this fortunate fact greatly simplified the problem, as we shall see. The "three-colour theory" divides the spectrum into three parts, the red, the green and the blue-violet. In the case of prints upon paper to be *viewed by daylight* the three separate impressions are all necessary if the resulting picture is to appear at all true to nature. But in the case of transparencies to be viewed by projection with some artificial light, the spectrum can be divided into two with very pleasing results. This is probably because a deficiency of colour at the violet end of the spectrum is not noticed in the absence of daylight.

But when the attempt was made to superimpose even this reduced number of records cinematographically, accurate registration still proved impossible—due again to the pictures slightly differing from each other, because of the use of two lenses in taking.

The next step was to take the pictures through one lens only, so as to ensure the same point of view for each, to take the two pictures (a red sensation and a blue-green sensation) in the time usually occupied in taking one picture, and to do this 16 times per second, making 32 pictures per second in alternate colour values.

The pictures were then projected on the screen *successively* at *twice the usual speed*, so that by "persistence of vision" the two-colour records would blend on the retina. This scheme worked very well up to a point. It became known as Kinemacolor. The system was officially used to record the glowing scenes of the Indian Delhi Durbar of King George and Queen Mary, in 1911-12, and exhibitions were given with considerable success in the principal cities of the world.

The Kinemacolor system, successful and pleasing though it was when well managed, had one or two practical drawbacks. One was that the film had to run in the projecting machine at twice the ordinary speed at least, so as to project 32 or more pictures per second instead of the 16 per second required for ordinary black and white pictures. The other and more serious drawback was that with *rapidly moving things* it was impossible to take the required *two* pictures (one in each colour) before the said subject moved, and this displacement of image caused bad "colour fringing" when projected on the screen. A lady kissing her hand from the casement window was apt to display a stream of red and green hands, an effect which rather destroyed the colour charm residing in the other portions of the picture where the action was less energetic.

This "fringing" defect naturally led to the conclusion that it is *absolutely necessary* to take two identical snapshots of everything *before it has time to move,* no matter what its speed. Two lenses are no good, because no matter how closely they are mounted together, they cannot take identical pictures. So what we really want is *a single lens that takes two pictures at once !*

A group of English experimenters, assisted by skilled English opticians, succeeded after many trials, in constructing an optical taking-system which secured this desirable result; and in due time pictures were taken by it and christened CINECHROME. Of course, in the evolution of the process they tried several schemes suggested by one and another, and as experience was gained gradually eliminated the faulty ones. The present Cinechrome process of taking *two identical snapshots* at once, successfully abolished the old fault of "fringing" due to phases of movement being missing; and it is the Cinechrome process of colour cinematography which I am going to demonstrate to you to-night.

But you might first like to see a simple diagram explaining the arrangement by which the two identical snapshots are secured.

AA: Cinematograph Film

---

* Messrs. Cinechrome, Ltd., 8 and 9, Long Acre, W.C.

The picture to be taken is on its way to lens 1, but first has to pass through the prisms A. These are cemented together with a silver ruling between them. Only half the rays of light can pass through the spaces of the ruling to lens 1, whence they carry their image through the red colour filter to the cinematograph film AA which is nearly double the usual width. The other half of the rays in the prisms marked A are stopped by the silver lines, and reflected to the silver sheet, as shown by the dotted line. From this silver sheet they are again reflected at 45° down the path of the dotted line to lens 2, whence the second image passes through a blue-green filter and deposits itself upon the sensitive cinematograph film by the side of the other one. One exposure will thus give us two pictures side-by-side, and identical in every respect. When the film moves through the camera by the ordinary cinematograph method, taking snapshots at the rate of 16 per second, we secure a double row of snapshots instead of the usual single row, and each row is a colour-value record derived from half of the spectrum.

To view these pictures in the full colours of the spectrum, all we have to do is to make a print from the negative and run it through a cinematograph projecting machine. From time to time, many complicated and expensive optical systems have been designed and tested, but to-day Messrs. Cinechrome, Ltd., use none of these. The present machine does not differ from the machines in use at the regular Cinemas—in fact, it can be used for ordinary black and white projection in any theatre, but, by a simple adjustment, it can take a double-width film when required, and by means of an extra lens project the two rows of pictures at once. By a few turns of a milled head the two lenses can be made to converge their beams so that the side-by-side pictures become superimposed on the screen. Each lens is provided with a colour filter of glass, somewhat similar to the filters used in the camera, so that when superimposed the two halves of the spectrum are brought together on the sheet. If presently you will glance at the machine when working, you will see that a beam of red light emerges from one lens, and a beam of bluish green light from the other. The two beams unite just before reaching the screen, and on its surface produce the re-composed scene, because the varying densities of the black and white cinematograph film intercept the beams of colour in varying proportions determined by the nature of the scene originally photographed.

The pictures to be shown to you to-night, all taken by the process described, are mainly of the tour of H.R.H. the Prince of Wales recently through India and Burma. I had the privilege of being attached to H.R.H.'s party as Official Cinematographer in Colour, and by the courtesy of the Indian Government had exclusive opportunities of taking pictures of every event of the long tour. The negatives were all developed in India under very primitive conditions—in a bath room, in fact, attached to the Connaught Hotel, at Poona, where members of the technical staff of the Cinechrome Company worked on them at night, which was the only time the water could be kept cool enough, even with ice.

You may possibly have the impression that the majority of these Indian pictures are lacking in *green*; hedges, trees and grass are sometimes inclined to be sandy. The explanation is that during the period of our visit, the winter, everything was very dry; I only recall one fall of rain during the 4½ months of my journeyings in India. I am informed that during the monsoon, or rainy period, the greens are as fresh and vivid as one can wish, but we were there during the dry period. In case you should imagine that the lack of bright greens is due to some fault in the process used, I shall start with a few miscellaneous pictures taken at home, when you will at once see that the bright greens, which we are accustomed to see in nature, are satisfactorily reproduced.

[At the close of the paper several reels of film were exhibited, chiefly illustrating the tour of H.R.H. the Prince of Wales in India. On this subject alone 3,500 ft. were projected. In addition Mr. Smith showed a number of miscellaneous subjects, chiefly in order to illustrate the fact, which was not so demonstrable in the Indian pictures, that the process could reproduce adequately the greens in Nature.]

DISCUSSION.

THE CHAIRMAN proposed a vote of thanks to Mr. Smith for his most admirable and convincing demonstration. He thought it was obvious to everyone that cinematography in colour was now practicable, at any rate so far as technical conditions were concerned. Whether this was a process which would satisfy the commercial world of cinematography was a matter which did not concern them at that meeting. He could only say that, having seen, he thought, a demonstration of every process of colour photography which had been offered to the public, he had never seen results which came near to those which Mr. Smith had exhibited that evening. It seemed incredible that these results should have been obtained by means of combination on the screen of two colours only. Many of those present would remember the results which in still photography were obtained years ago by Mr. F. E. Ives, who was a great pioneer in these processes. Mr. Ives employed three colours—red, green, and blue-violet projections. Mr. Ives' colour photographs, both on the screen and also in his viewing instruments, were very beautiful; they were probably as beautiful examples of colour photography as had been made up to the present, but when one looked at some of the film records which Mr. Smith had shown that evening, and particularly some of the Indian landscapes, one could hardly believe that they were not made by the much more complicated three-colour method which Mr. Ives used more than 20 years ago. But he believed that Mr. Smith would agree with him that the problems he had to surmount had not been chiefly photographic problems, but mechanical and optical ones, the optical problem being to make the two images come exactly into register, and the mechanical problem that of showing each of the two pictures at exactly the same instant.

Lord Askwith, K.C.B., K.C., D.C.L. (Chairman of the Council), seconded the vote of thanks with the greatest pleasure. If Mr. Albert Smith had done nothing else, he had at least brought into the minds of the audience that evening some warmth and some colour on a very grey, if not black, day in the City of London. He had also shown the wonderful scenes in India which accompanied the Prince of Wales's tour. Looking at those photographs some people might think that India was quite a small country after all, because Mr. Smith had managed to show so much of it in one evening. He had darted from Rangoon to Mysore, then to Hyderabad and to Gwalior, Nepal, Lahore, Peshawar and back to the starting point at Bombay. The costumes, the vivid colour, and the interesting people whom he had shown would, however, bring back to the mind something of the vast extent of India. He was of opinion that perhaps the most interesting picture Mr. Smith had shown was that of the elephant procession at Gwalior, and he wondered whether the elephants recognised each other in their extraordinary dress. Mr. Smith appeared to be rather sorry for himself because he went up that steep hill at Gwalior on the back of an elephant, but the speaker could tell him that if he had walked up the hill on a hot day he would have found it much worse. It was many years ago since he went to Gwalior, but the heat of the day and the climb up that hill would never be forgotten by him for the rest of his life. Mr. Smith had also done a great work in bringing back these photographs, because they placed on record, probably for all time, one of the most interesting journeys of the Prince during recent years. Conditions in India as the decades went by might change rapidly, and therefore the record was all the more valuable. The colour photography had an obvious advantage to which black and white photography could never pretend. It brought before them the marvellous colour of the East, especially the reds and the golds, and it also illustrated the sort of atmosphere and movement which there existed. He seconded the vote of thanks with much pleasure.

The vote of thanks was accorded unanimously.

Mr. Albert Smith thanked the Chairman and Lord Askwith for the complimentary way in which they had proposed and seconded the vote of thanks. The audience had already paid him the greatest compliment—that of complete attention—and this he appreciated most warmly. The Chairman had drawn attention to the fact that in the completion and carrying through of this process great mechanical difficulties had to be surmounted. The credit for that mechanical work ought to go to Messrs. Cinechrome Ltd., who had been engaged for such a long time in perfecting this process. It was to the clever engineers of that Company that the greatest part of the credit belonged. He himself had done his best to contribute what little knowledge and help he could so far as the colour part of the work was concerned, but the technical and mechanical part of it was beyond his powers. Messrs. Cinechrome Ltd., did not feel that they had reached finality in this respect, but they had reached a point at which the process was workable. The process had not been offered to anyone else in the commercial sense, and these films had not been exhibited except to bodies like the Royal Society of Arts and to officials of the India Office and elsewhere. There might still be a good deal of work to be done before the process could go before the public. Once more he thanked them for the kind and appreciative manner in which they had followed the paper and demonstration.

The proceedings then terminated.

OBITUARY.

Francis John Waring, C.M.G., M.Inst.C.E.—Mr. Francis John Waring died at his residence at Ealing on February 6th, at the age of 80. After being educated at King's College School, he proceeded to India, where he was engaged on the Indus Valley railway survey, and subsequently on the construction of the Delhi Railway. In 1872 he went to Brazil, on his appointment to the Sao Francisco and Tocantius railway survey, and three years later he entered the service of the Ceylon Government as district engineer, subsequently becoming chief resident engineer. He was responsible for the construction of various mountain railways, and made a trigonometrical survey of Adam's Bridge to connect India and Ceylon.

In 1896 Mr. Waring returned to this country and set up in practice in Westminster. He held a large number of appointments, being consulting and inspecting engineer to the Crown Agents for the Colonies for the Government railways in Ceylon, the Malay Straits, Trinidad, Nyasaland, and for the Demerara, British North Borneo, and Central Africa Railways. He was awarded a Telford premium and a Crampton prize for papers read before the Institution of Civil Engineers.

Mr. Waring was elected a member of the Royal Society of Arts in 1892, and he spoke in discussions and contributed letters to the *Journal* from time to time.

NOTES ON BOOKS.

Mechanical Road Transport. By C. G. Conradi. London: Macdonald and Evans. 21s. net.

This handsome volume of 394 demy octavo pages, with its plates and numerous engravings in the text, is an exhaustive, lucidly written and well illustrated monograph on commercial traffic on the highways—i.e. both persons and goods, but excluding the private pleasure car.

Direct motor traffic from source to destination, without change or delay at terminals—and often without packing, seems to offer a fascinating prospect for long distance delivery and for mitigating congestion on the railways. Indeed, Mr. Conradi foreshadows the time when that progress in legislation which he details (p. 10), may culminate in the allowing of motor-trains on our highways. He points out that properly designed road-trains, in which both the driving and the load are distributed over the whole length of the train, may carry large tonnage with a minimum of road-wear; reference being made to demonstrations by Renard and to the more recent trials by Durtnall.

In his comprehensive chapter on Fuels, Mr. Conradi touches on the question of gaseous fuel for road traffic, and despite the theoretical economy of producer gas and statements regarding a commercial "producer" vehicle having been run satisfactorily for two years, the author considers it to be extremely problematical whether such a system can ever be a commercial success; the gas "producer" being so inherently slow to a sudden call for more power, to say nothing of tendency towards corrosion.

Gas supplied from an outside source and either bagged, or under high compression comes into quite another category and considerable space and many illustrations show the various outcomes of the pioneer work done in this direction by Messrs. Barton of Beeston. Perhaps the most promising aspect of gas fuel is the use of grouped compression cylinders, and automatic release into a low-pressure flexible holder, as depicted by Fig. 12, p. 39.

In a thorough and masterly manner, Mr. Conradi guides his readers through the long range of parts from the magneto to the automatic diary or work recorder (Fig. 180, pp. 257-8); from the Bantam truck for 10 cwts. to 6-wheel or 8-wheel systems of which a portion may be disconnected (pp. 202-204, Figs. 121, 122, 124, 125, 133); laws and regulations, from the Carriers Act of 1830 to the scale of taxation under the Act of 1920; working costs, from interest on capital to lubricating oil and waste; and finally books or writings from Stuart's Anecdotes of steam engines to O'Neill on Colloidal Fuel.

The publishers and Mr. Conradi are to be congratulated on the present volume, and as road transport takes new aspects we may expect new editions.

The Co-operative Movement in Japan. By Kioshi Ogata, with a Preface by Sidney Webb. London: P. S. King and Son. 12s. 6d.

In several respects this work is remarkable, as it embodies elements of research and tabulation which bear pertinently on vital questions of world-wide importance.

Even if Dr. Ogata's study of the recent activities of co-operators in Japan had been a bare history of the movement, it would have possessed notable value as a contribution to social history; but he has supplemented the unbroken and sequent story by abundant footnotes which give particulars as to co-operative activities in other countries, views of authorities, historical or legal items, cross references to the text, and such numerous details as make the work one of altogether exceptional value to those who are interested in social thought or progress.

The author makes it clear that the numerous co-operative units now existing in Japan are generally, or perhaps entirely, free from or independent of Socialistic tendency, and are spontaneous efforts of the industrial classes to associate themselves for mutual advantage. The Japanese Government, which is not favourable to Socialistic doctrine, rather assists the co-operators, by such aid as can be afforded without material risk or loss to the public funds; this aid being, in the main, analogous to the facilities given to the various building societies by the British Government from about 1846 forward; and there is considerable analogy between the local credit banks of Japan, which are the financial bases of the co-operative societies, and the Starr-Bowkett Building Societies, of which it is said there were at one time more than 1000 in Great Britain (pp. 18-22).

We may probably assume the co-operators of our Building Society period, as also the Rochdale pioneers, and those who laid the foundations of the Civil Service Supply Association, to have acted quite independently of any political motive or of any notion of promoting Socialistic doctrines; and the generally favourable attitude of the British Governments, like that of the present Japanese Government, may be attributed to a wish to minimise Socialistic propagandism, and to weaken any arguments for revolutionary socialism. Thus, the account of spontaneous Japanese co-operation as told in the work before us is admirably illustrative of co-operation as something apart, as a sect, or in its separate and independent condition; that is to say, in strong contrast with the so-called co-operative movements engineered in France by Godin and by Fourier, also in Great Britain by Robert Owen. These men were ardent socialists, and endeavoured to promote Socialism by something called co-operation, but it was little more than a blind obedience of the workers to the dicta of the well meaning autocrat who supplied funds and imagined schemes of social reconstruction.

Professor Ogata's scholarly method of studying actual events, touching on historical parallels with a light hand, and showing considerable diffidence or caution in arriving at conclusions, gives us the kind of treatise which is now required.

A good example of his mode of study is to be found (pp. 182-187), where he treats of the obstacles to co-operative progress in Japan, and considers causes of failure as exemplified by some 4,000 societies which have fallen out by the way during a certain period.

This study of failures when considered in contrast with the much greater record of successes, as given in pp. 174-181, suggests a stage in social fluidity: a stage at which there is a very distinct tendency towards the survival of the better forms and the extinction of those subject to degenerative influences; "disloyalty," "apathy," "discord," "inefficiency of the elected officials" (pp. 185-186).

In his story of healthy growth under this natural or automatic process of weeding out the unfit, Professor Ogata's story seems to lead us towards a better understanding of the ancient concept of the social group, State, or administrative-unit as an organism. Birth, growth, death and susceptibility to either melioration or pejoration are characteristics common to all organisms, and if the above mentioned parallel is to be made to bear on applied economics, some method must be devised to give a self-extinguishing tendency to inefficient public departments, comparable to that self extinguishing tendency which now looms over inefficient private businesses, associations, or joint stock companies.

The application of the organism notion to the high senate of the ultimate or ideal state of the Marxians is more difficult, as, should such a state be possible, and actually realised, every condition like competitive stress and purgation must be at an end.

On the side of confident prediction as to the possibility and desirability of the ideal Marxian state, the student may well read the "Fabian Essays in Socialism" (Walter Scott). The "Democracy and Reaction" of L. T. Hobhouse (T. Fisher Unwin), suggests a doubt whether even a near approach to such an ideal state is possible, and that something comparable to a period of diminishing, disappearing or reversed returns may step in at an early period, and the work now under notice gives concrete instances of great value, as tending to cast indirect light on these problems.

THE SOUTH AMERICAN HANDBOOK, 1924. London: South American Publications, Ltd. 7*s*. 6*d*. net.

This handbook, excellently written and excellently planned, is packed so full of information that in writing a short notice of it one hardly knows what to select for comment. Perhaps the most interesting pages are those which describe the journey across the Andes. The railroad climbs with wonderfully even gradients from Mollendo on the coast of Peru to the enormous height of 14,688 feet, which it attains at a distance of 210 miles from the sea. The scenery is amongst the grandest in the world, and this is not the only charm of the journey. Cuzco, which witnessed the rise and fall of the Inca Empire is a city of intense interest to the historian and archæologist, as well as to the sculptor and painter. Its fortress of Sachsahuaman ranks among the wonders of the world, and it is uncertain whether it dates from Incaic or pre-Incaic times. Almost every street in the town has remains of Incaic or pre-Incaic stonework, the perfection of which fills the architect of to-day with admiration and amazement.

"It is curious," says the Handbook, "after travelling for several days on the Southern Railway in the high altitudes of the Andes, to alight on the shores of Lake Titicaca and see at the pier a vessel which has the appearance and almost the size of an ocean liner." The surface of the lake is some 12,500 feet above sea level, and it was no mean engineering feat to bring up to this height by railway the various parts of the S.S. "Inca" and reassemble them on the lake. The "Inca" is 128 ft. long, and has a 46 ft. beam, with quarters for 86 first-class passengers, and is rated for 1,000 tons of cargo. Her predecessor, the "Yapura," which has been navigating the lake since 1861, was brought all the way from the sea on backs of Indians and mules.

Lake Titicaca is not only one of the largest, but also one of the most beautiful of inland waters. Some of the mountain peaks rise nearly two miles above the surface of the water, and the beauty of the view just before sunrise, when seventy-five miles of perpetual snow emerge from the darkness, is said to be unsurpassed.

One Hundred Years' History of the Chinese in Singapore. By Song Ong Siang, M.A., LL.M. (Cantab.). London: John Murray.

Singapore was founded as a settlement by Sir Stamford Raffles, on February 6th, 1819. At that time the population of the island amounted to about 150 fishermen and pirates living in a few miserable huts: about thirty of these were Chinese, and the rest Malays. In little more than a year the population had risen to ten or twelve thousand souls, principally Chinese. Thanks to its geographical situation, which has made it extremely convenient as a trade depot, this increase has been steadily maintained until at the last census in 1921, the population was returned at 350,355, of whom some 70 per cent. were Chinese; while the harbour, in the extent of its shipping, is one of the greatest in the world, the number of vessels entered and cleared in 1922, exclusive of native craft, being 11,738, with a tonnage of 18,280,279.

The present work is described by the author as "a chronological record of the contribution by the Chinese community to the development, progress and prosperity of Singapore; of events and incidents concerning the whole or sections of that community; and of the lives, pursuits and public services of individual members thereof from the foundation of Singaporion, 6th February, 1819, to its centenary on the 6th February, 1919." The record has been divided into ten decades, and Mr. Song Ong Siang has certainly spared no pains in investigating the materials at his disposal; indeed, if we have a fault to find with the work it is that there is so much detail that it is difficult to see the wood for the leaves. This, however, is a fault on the right side, and one that it is difficult to avoid in a book of this description. The author has had to investigate the careers of a great many of his fellow-countrymen, and he has been fortunate in finding photographs of many of them, which certainly add a great interest to the volume.

As one would expect when one considers their number, the Chinese of Singapore have been of all sorts, good, bad and indifferent. Amongst those first mentioned in the book was one who was hanged for murder at the first Criminal Sessions held in 1828, and from time to time great trouble was given to the authorities by the lawless secret societies which won for themselves an unenviable reputation, and flourished on vice and crime. On the other hand a large proportion of the Chinese were hard-working folk, and it was largely owing to their peaceful and industrious habits that the trade of Singapore developed as it did. Nor can one help being struck by the large amount of public spirit among the leaders of the Chinese community of Singapore; the generosity of the merchant princes is manifested over and over again, and their readiness to contribute to charitable and educational institutions is most admirable.

Mr. Song Ong Siang has carried out a difficult and laborious task with great success, and he leaves us with a very pleasant impression of his fellow-countrymen in Singapore.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 20.—Percival James Burgess, M.A., F.C.S., Chairman, Rubber Growers' Association, "New Uses for Rubber." Sir Stanley Bois, late Chairman of the Ceylon Chamber of Commerce, will preside.

February 27.—Charles S. Myers, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation." Sir Robert Blair, LL.D., Education Officer, London County Council, will preside.

March 5.—Major-General Sir Fabian Ware, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

March 12.—Alan A. Campbell Swinton, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.) Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., will preside.

March 19.—R. L. Robinson, Member of the Forestry Commission, "The Forests and Timber Supply of North America." Lord Lovat, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., will preside.

March 26.—Neal Green, "The Fishing Industry and its By-Products."

April 2.—Sir Lynden Macassey, K.B.E., "London Traffic."

April 9.—Frank Hope-Jones, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." Professor C. Vernon Boys, F.R.S., will preside.

April 30.—Brigadier-General Sir Henry Maybury, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "Roads."

May 7.—J. Robinson, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

May 14.—

May 19 (Monday).—**Sir James Fortescue-Flannery**, Bt., Ex-President, Institution of Marine Engineers, "Marine Internal Combustion Engines." **The Rt. Hon. Lord Bearsted** will preside.

May 21.—**Professor C. Vernon Boys**, F.R.S., "Calorimetry." (Trueman Wood Lecture.)

May 28.—**Mrs. Arthur McGrath** (Rosita Forbes), "The Position of the Arabs in Art and Literature." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Dates to be hereafter announced :—

T. Thorne Baker, "Photography in Industry, Science and Medicine."

Indian Section.

Friday afternoons at 4.30 o'clock :—

March 21.—**Otto Rothfeld**, I.C.S., "Progress of Co-operative Banking in India."

May 2.—**Jocelyn F. Thorpe**, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced :—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

Dominions and Colonies Section.

Tuesday afternoons at 4.30 o'clock :—

March 4.—**The Hon. T. G. Coohrane**, D.S.O., "Empire Oil: The Progress of Sarawak." **The Rt. Hon. Lord Bearsted** will preside.

May 27.—**C. Gilbert Cullis**, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Cantor Lectures.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

Syllabus.

Lecture I.—**February 25.**—The carbonisation of coal considered as a process for distributing the thermal energy of the coal into therms in the form of gas, tar and coke. Factors which cause wastage of therms in the form of gas and the principles underlying high yields of gaseous therms.

Lecture II.—**March 3.**—The inter-relation of therms in the form of gas and tar and the process conditions which affect their distribution. Further principles underlying high yields of gaseous therms. The chemistry and economics of tar cracking.

Lecture III.—**March 10.**—The trend of developments in carbonising processes. The de-ashing of coal and other factors tending to increase the value of the therm in the form of coke.

Cobb Lectures.

Monday evenings, at 8 o'clock :—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31 ; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, February 18..British Architects, Royal Institute of, at the Royal Society, Burlington House, Piccadilly, W., 8 p.m. Mr. Paul Waterhouse, "The Charing Cross Bridge."

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Prof. G. M. Price, "Geology in its relation to Scripture Revelation."

Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 5.30 p.m. Mr. R. C. Reynolds, "Salient Points in Transport Accountancy."

Electrical Engineers, Institution of, (Informal Meeting), 7 p.m. Dr. E. M. Maick, "Electrical Development in France."

Faraday Society, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1. Principal A. P. Laurie, "Suggestions for a Magnetic Theory of Valency." 2. Prof. T. M. Lowry, "The Electronic Theory of Valency. Part IV. The Origin of Acidity." 3. Messrs. E. Hatschek and R. H. Humphry, "On Certain Physical Differences between Sols and Gels of Agar." 4. Profs. D. C. Henry and A. V. Morris, "The Influence of Anions in the Coagulation of a Negative Colloidal Sol." 5. Messrs. E. B. R. Prideaux and W. E. Crooks, "The Diffusion Potentials of Benzoates and Salicylates and their Modification by Membrane of Parchment Paper."

Geographical Society, Lowther Lodge, Kensington Gore, S.W., 5 p.m. Mr. E. Heawood, "The Use of Watermarks in Dating Old Maps."

University of London, University College, Gower Street, W.C., 5.15 p.m. Dr. A. S. Parkes, "The Mammalean Sex-Ratio." (Lecture IV.)

At Kings College, Strand, W.C., 5.30 p.m. Rev. C. F. Rogers, "Ecclesiastical Music." (Lecture III.)

5.30 p.m. Dr. R. W. Seton-Watson, "A Survey of Bohemian History." (Lecture III.)

East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Mr. J. C. French, "Continuity in Indian Art."

Tuesday, February 19..Statistical Society at the Royal Society of Arts, John Street, Adelphi, W.C., 5.15 p.m. Mr. R. Y. Sanders, "Foreign Trade and Shipbuilding."

Illuminating Engineering Society, at the Royal Society of Arts, John Street, Adelphi, W.C., 8 p.m. Messrs. J. F. Caine and E. A. Marx, "Some Aspects of Railway Lighting."

Civil Engineers, Institution of, Great George Street, S.W. ,6 p.m.

Anthropological Institute, at the Royal Society, Burlington House, Piccadilly, W., 8.15 p.m. Dr. E. Jones, "Psycho-Analysis and Anthropology."

Mineralogical Society, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. J. Barcroft, "The Respiratory Pigments in Animal Life." (Lecture II.)

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. P. King, "The Camera and the Human Eye: a Comparison."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. D. H. Owen, Experiment on a Cylindrical Steam Boiler with and without pre-heated Air."

Embroiderers' Guild, at the Victoria and Albert Museum, South Kensington, S.W., 3 p.m. Capt. Kettlewell, "The Heraldry and Arrangement of Banners."

University of London, University College, Gower Sttreet, W.C., 5.30 p.m. Mr. J. H. Helweg," Modern Danish Lyrics 1870-1920." (Lecture III.).
5.30 p.m. Mr. N. H. Baynes, "The Roman Empire and its Invaders." (Lecture III.)
At King's College, Strand, W.C., 5 p.m. Rev. Prof. F. C. Burkitt, "Christian Beginnings." (Lecture III.)
5.30 p.m. Sir Bernard Pares, "Russia Before Peter the Great to 1861." (Lecture V.)
5.30 p.m. Dr. H. W. Carr, "The Transition to the Relativist Conception of Nature." (Lecture III.)
5.30 p.m. Mr. J. R. Beard, "Electric Power Mains." (Lecture III.)

WEDNESDAY, FEBRUARY 20..United Service Institution, Whitehall, S.W., 3 p.m. Air-Commander A. H. Clark-Hall, "The Value of Civil Aviation as a Reserve in the Royal Air Force in the Time of War."

Meteorological Society, 49, Cromwell Road, S.W., 7.30 p.m.

Transport, Institute of, (Local Section), The University, Liverpool. Prof. E. R. Dewsnup "Some Aspects of the Problem of Inland Transport."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p m. Mr. F. Hughes, "Can Industry be Divorced from Politics?"

Economics and Political Science, London School of, Houghton Street, Aldwych, W.C., 6 p.m. Prof. R. Muir, "The Institutions of the Empire."

University of London, University College, Gower Street, W.C., 5.30 p.m. Prof. Geyl, "English Diplomacy in Holland in the XVIII. Century." (Lecture II.)
5.30 p.m. Mr. I. C. Gróndahl, "Contemporary Norwegian Literature." (Lecture III.).
5.30 p.m. Mr. J. G. Pearce, "The Work of Special Libraries and Intelligence Bureaux in Industry."
6. p.m. Prof. Karl Pearson, "The Current Work of the Biometric and Eugenics Laboratories." (Lecture II.)
At King's College, Strand, W.C., 5.30 p.m. Mr. A. Vallance, "Old Timber Houses."

THURSDAY, FEBRUARY 21..Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. H. H. Thomas, "Aerial Photography and Survey."

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. Sir W. Bragg, "Crystalline Structure of Organic Substances." (Lecture III.)

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Mr. T. Dean, "The Dalton Plan in Practice."

Constructive Birth Control, Society for, Essex Hall, Strand, W.C., 8 p.m. Dr. Maude E. Kerslake, "Why we want Clinics."

Economics and Political Science, London School of, Houghton Street, Aldwych, W.C., 5 p.m. Sir Hubert L. Smith, "The Economic Laws of Art Production." (Lecture VI.).

Linnean Society, Burlington House, Piccadilly, W., 5 p.m.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1. Messrs. T. M. Lowry and E. M. Richards, "The rotatory dispersive power of organic compounds. Part XI Octyl Alcohol and Octyl Oxalate." 2 Messrs. J. O. Cutter and T. M. Lowry, (a) "The Rotatory Dispersive power of organic compounds. Part XII. Borneol, Camphor and Camphorquinone. Asymmetric atoms and asymmetric molecules." (b) "The Rotatory Dispersive Power of Organic compounds. Part XIII. Halogen-derivatives of camphor. Optical superposition in the camphor series." 3. Mr. H. Hunter, "Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XXII. Simple and complex rotatory dispersion.'

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. I. Bjórkhagen, "Modern Swedish Prose Authors." (Lecture III.)
5.15 p.m. Prof. J. E. G. Montmorency, "Comparative Customary Law in Europe and Asia." (Lecture V.)
At. King's College, Strand, W.C., 5.30 p.m. Dr. E. W. Scripture, "The Psycho-Analysis of the Poet."
5.30 p.m. Prince D. S. Mirsky, "The History of Russian Literature." (Lecture V.)
5.30 p.m. Dr. H. Lamb, "The Internal Constitution of this Earth." (Lecture II.)
At the London School of Economics, Houghton Street, Aldwych, W.C., 5 p.m. Dr. J. H. Clapham, "Britain on the Eve of the Railway Age." (Lecture I.)
At St. Mary's Hospital Medical School, Praed Street, W., 5 p.m. Prof. B. J. Collingwood, "Blood." (Lecture I.)

London County Council, Geffrye Museum, Kingsland Road, E., 7.30 p.m. Mr. H. A. Tipping ("Furniture" Part I.), "The Dining Room from the Earliest Times to the Present Day."

Tropical Medicine and Hygiene, Royal Society of, 11, Chandos Street, W., 8.15 p.m. Prof. F. Kleine, "Recent Expedition to Africa to Investigate the Action of Bayer 205."

FRIDAY, FEBRUARY 22. Engineering Inspection, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Mr. M. W. Baseden, "The Oscilloscope."

Royal Institution, Albemarle Street, W., 9 p.m. Prof. G. Elliot Smith, "The Human Brain."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. C. P. Crowther, "Portraiture and Portable Lighting."

Physical Society, at the Imperial College of Science, South Kensington, S.W., 5 p.m.

Aeronautical Engineers, Institution of, Engineers' Club, Coventry Street, W., 6.30 p.m. Mr. W. O. Manning, "Low-powered Flying."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Annual General Meeting.

University of London, at King's College, Strand, W.C., 5.30 p.m. Dr. H. Lamb, "The Internal Constitution of the Earth." (Lecture II.)
5.30 p.m. Prof. R. W. Seton-Watson, "The Rise of Nationality in the Balkans." (Lecture V.)
5.30 p.m. (Shakespeare Assoc.) Prof. S. Boyanus, "The Beginnings of English Stagery."
At the London School of Economics, Houghton Street, Aldwych, W.C., 5 p.m. Prof. A. P. Brigham, "The Geography of the United States, Regional and National." (Lecture I.)

SATURDAY, FEBRUARY 23..Royal Institution, Albemarle Street, W., 3 p.m. Mr. W. de la Mare "Imaginative Prose."

London County Council, Horniman Museum, Forest Hill, S.E., 3.30 p.m. Miss M. A. Murray, "Animals in the Religion of the Ancient Egyptians."

Journal of the Royal Society of Arts.

No. 3,718. VOL. LXXII.

FRIDAY, FEBRUARY 22, 1924.

22 MAR 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 25th, at 8 p.m. (Cantor Lecture.) **EDWARD VICTOR EVANS**, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Lecture I.

WEDNESDAY, FEBRUARY 27th, at 8 p.m. (Ordinary Meeting.) **CHARLES S. MYERS**, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The use of Psychological Tests in the Selection of a Vocation." **SIR ROBERT BLAIR**, LL.D., Education Officer, London County Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

A meeting of the Council was held on Monday, February 11th. Present:—

Lord Askwith, K.C.B., K.C., D.C.L. (in the Chair); Sir Charles S. Bayley, G.C.I.E., K.C.S.I.; Mr. A. Chaston Chapman F.R.S.; Sir William Henry Davison, K.B.E., D.L., M.P.; Mr. Edward Dent, M.A.; Mr. P. M. Evans, M.A., LL.D.; Sir Thomas Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S.; Sir Philip Magnus, Bt.; Dr. William Henry Maw, M.Inst.C.E.; Hon. Sir Charles A. Parsons, K.C.B., LL.D., D.Sc., F.R.S.; Mr. Alan A. Campbell Swinton, F.R.S.; Mr. Carmichael Thomas; Dr. J. Augustus Voelcker, M.A., and Sir Frank Warner, K.B.E.; with Mr. G. K. Menzies, M.A. (Secretary of the Society) and Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

PROFESSOR C. VERNON BOYS, F.R.S., was appointed to deliver the Trueman Wood lecture on "Calorimetry."

SIR FRANK BAINES, C.V.O., C.B.E., was appointed to represent the Society on the Chadwick Trust.

Arrangements for papers and lectures were considered.

Other formal business was transacted.

SWINEY PRIZE.

A meeting of the adjudicators of the Swiney Prize, appointed under the will of the late Dr. George Swiney, was held at 5 p.m. on Monday, February 11th, 1924, at the house of the Royal Society of Arts. Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, was in the chair.

The **CHAIRMAN** reported that the Committee appointed by the Council of the Royal Society of Arts, had examined the works submitted for the prize, and were unanimously of opinion that the prize should be awarded to Sir Paul Vinogradoff, for his work, "Outlines of Historical Jurisprudence."

On the motion of the **CHAIRMAN**, seconded by **SIR HUMPHRY ROLLESTON**, K.C.B., M.D., D.C.L., LL.D., President of the Royal College of Physicians, it was thereupon unanimously resolved: "That the Swiney Prize be adjudged to **PROFESSOR SIR PAUL VINOGRADOFF**, F.B.A., for his work, 'Outlines of Historical Jurisprudence.'"

TENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 13th, 1924: **SIR ASTON WEBB**, K.C.V.O., C.B., P.R.A., a Vice-President of the Society, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Franzen, Raymond, Ph.D., Berkeley, California, U.S.A.
McCall, William A., Ph.D., New York City, U.S.A.
Mattu, Pandit Jagar Nath, Srinagar, India.
Shaw, Professor Frederick William, B.S., M.D., Rolla, Missouri, U.S.A.

The following candidate was duly elected a Fellow of the Society:—

Aslam, Syed Mohammad, B.A., Oxford.

A paper on "The Preservation of Timber Roofs from the Death-Watch Beetle," was read by **PROFESSOR H. MAXWELL-LEFROY**.

The paper and discussion will be published in a subsequent number of the *Journal*.

INDIAN SECTION.

Friday, February 15th, 1924. The **Right Hon. Lord Meston, K.C.S.I., LL.D.,** in the Chair.

A paper on "Salt Manufacture in India," was read by **Sir Richard M. Dane, K.C.I.E.,** Commissioner, North India Salt Revenue, 1898-1907, and Inspector-General of Excise and Salt for India, 1907-09.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

◆

NINTH ORDINARY MEETING.

Wednesday, February 6th, 1924.

Lord Askwith, K.C.B., K.C., D.C.L. (Chairman of the Council) in the Chair.

The Chairman, in introducing the lecturer, said he was not going to say one word about the calamity which was the subject of the paper, because he desired the audience to hear of it first-hand, from one who knew about it through his relatives and friends in Japan, and who would show films of the actual event. Mr. Iyemasa Tokugawa was a gentleman now in the Japanese Embassy in London. He had been in London in his youth for several years; had then been Secretary to the Foreign Office in Tokio, at the outbreak of the War; had afterwards gone to Pekin and Washington, and had then returned to this country. Mr. Tokugawa was, therefore, well-known in England, and knew the English.. Further, Mr. Tokugawa spoke as a man bound up with Tokio by his ancestry and by his own life. For generations the family of Tokugawa had been connected with Tokio. The lecturer's grandfather, after 15 generations of the Shogunate which they had established in Tokio (then, he thought, called Yedo)—had been the last Shogun, and when the Shogunate gave place to the Imperial dynasty, the son of the last Shogun (now President of the House of Peers in Japan) was given the dignity of a Prince. He, with his son, was present at the Disarmament Congress at Washington on behalf of his country, and at the present time was the head of the local Organisation in Tokio, in addition to being connected with the various Imperial, Foreign and National enterprises, for the relief of the terrible distress which had arisen in consequence of the calamity. Mr. Tokugawa, the son of Prince Tokugawa, therefore, spoke about a city which was in his blood by his ancestry, and by his own connection with it. He spoke of it with sympathy and with knowledge, from the accounts which had come from his near relatives in that neighbourhood, no one of whom, he was glad to say, had died in the catastrophe which had proved such a tragedy to so many families.

The paper read was :—

THE EARTHQUAKE AND THE WORK ON RECONSTRUCTION IN JAPAN.

By **Iyemasa Tokugawa, O.B.E.,**
First Secretary to the Japanese Embassy.

It is a very great honour and privilege to give such a distinguished and learned gathering to-night some account of the recent earthquake disaster in Japan and the work of reconstruction now in progress. I must tell you first of all that as I have not been an eye-witness of the horror, my account of the catastrophe is based on official and other reports, on letters from my friends and relatives in Japan, and also on what has been told by those who have come to London after their terrible experiences in Tokio or Yokohama.

Before proceeding to the main topic of my paper, it may perhaps be better to lay before you a very general topographical description of Japan, and, in particular, the districts which were affected by the earthquake. To those of you who have been to Japan, this may seem superfluous, but, for others who are not quite so familiar with the geography of Japan, just a few words on that subject may be acceptable.

Japan proper, if we omit Corea for the moment, is a long cluster of islands extending over about 37 degrees of longitude and 29 degrees of latitude. There are six large islands. The largest one, Hondo, that is the main island, lies in the middle. Hokkaido, next in size, is up in the north. Still further north, there is Saghalien, the southern half of which is Japanese, the other half being Russian. The other three are Kyushu, Taiwan—that is, Formosa,—and Shikoku, in order of size. For the present purpose, we shall confine our attention only to Hondo, the Main Island. The Pacific Ocean washes the eastern shores of this island, and at a point not far from the north-east coast, there is the deepest sea bed in the world ever surveyed, called, after the name of the American warship, Tuscarora Deep. However, this is by the way. Coming down southward along the north-eastern coast I have mentioned, almost the first bay worthy of attention is the Bay of Tokio, with the Boso and Miura Peninsulas on both sides. Tokio, the capital, is situated at the inside of the Bay, and Yokohama, one of the chief sea ports of Japan, especially in relation to the trade with America, is about 20 miles south of Tokio on the west coast of the Bay. Further south on the same side of the Bay, there is Yokosuka, the oldest and one of the largest naval stations in Japan. Westward from Tokio Bay, there are many indentations of considerable size. On the west side of the Miura Peninsula, there is the Sea of Sagami, in the centre of which there is a volcanic island called Oshima, and, on the coast, there are famous sea-side resorts, such as Dzushi, Kamakura, Enoshima, Oiso, etc. On the other side of the bay, there lies the Idzu Peninsula, which, on its west, has the Bay of Suruga. The next bay is the Bay of Isé, and then, there is the Kii Channel, which divides the Main Island from Shikoku. If you proceed up that channel to the north, you find the Bay of Osaka. Another sea-port of international importance, Kobé, is on the west coast of it, and, at the inside of the bay, there is Osaka, another seaport of less international importance, but the greatest industrial city in Japan.

One of the main railway lines,—as a matter of fact the most important line,—called the Tokaido Line, connects Tokio and Kobé, running practically all the way along the Pacific coast, and extending further westward from Kobé to Shimonoseki, almost the westernmost point of the Main Island. There is another railway called the Nakasendo Line, running more inland parallel to the Tokaido Line, although it joins the Tokaido Line somewhere near the Bay of Isé. At the other end of this system is a station on a railway running northward from Tokio. Thus, in case of need, when the Tokaido Line is not available, as sometimes happens after a typhoon which visits the Pacific coast at the end of almost every summer, this Nakasendo Line serves as a substitute for the former, although in a much more round-about way.

The main Island is traversed from north to south by a range of mountains. The most famous is Mount Fuji, which stands about ten miles to the north of the sea-coast of the Bay of Suruga. Its remarkable grace, its shape almost symmetrical all round makes it one of the most beautiful mountains in the world. Near Mount Fuji starts the Hakoné range, which runs southward into the Idzu Peninsula. This is famous for the numerous hot springs in the Hakoné districts. The name of Miyanoshita is probably quite familiar to you, and it is the most popular resort in the neighbourhood.

The whole of Japan is divided in prefectures for administrative purposes. Greater Tokio constitutes a prefecture by itself. To the east of Tokio, there is the Chiba Prefecture, which practically covers the Boso Peninsula already mentioned. Yokohama, the whole Miura Peninsula and the other Sagami districts, which cover the greater part of the sea-board of the Bay of Sagami, are in the Kanagawa Prefecture. To the north of Tokio, there is the Saitama Prefecture, while on the other hand the greater part of the Idzu Peninsula is in Shidzuoka Prefecture. I mention these Prefectures, because these were wholly or partially affected by the earthquake.

Now let us come back to the question of the earthquake itself.

Japan experienced a very hot summer last year, and, on the morning of Saturday, September 1st, there was a strong gale in Tokio and its neighbourhood, and had it continued to blow, as was feared naturally enough at this time of the year, it might indeed have caused by itself considerable damage. But by 10 o'clock in the morning of that day, the gale ceased, and everybody in town and in the country was looking forward to the enjoyment of a quiet late summer Saturday afternoon. In Japan, noon is the lunch time, and that hour had almost arrived, when at eleven o'clock, fifty-eight minutes and forty-seven seconds, suddenly an extraordinary rumbling of the ground was heard, and a moment had scarcely passed, when the first violent shock of earthquake started the work of terrible destruction. It came brutally, tossing up and then mercilessly shaking the earth over a very wide range. Everybody and everything on earth lost all control. It is no exaggeration to say that people thought it was the end of the world.

According to the personal narrative of the captain of a Canadian liner which was then in the harbour, he saw the whole flat city of Yokohama billowing like the surface of the ocean under a great storm, and all the houses and vehicles seemed exactly like ships drifting about at the mercy of the waves. The next moment clouds of dust caused by the falling of houses covered the scene, and then the smoke from the fire which followed blotted the whole city out of sight.

One earthquake shock followed another; during the first twelve hours about 114 shocks were experienced; during the twelve hours following, there were 88; during the third 60, and during the fourth 47, and so on, and some of them were almost as severe as the first. If you add to these the other shocks which a seismograph alone could record, there were, during the first three days, more than 1,700 shocks in Tokio. This was not all. Shocks were felt almost every day, although gradually diminishing in violence, until November. Of course, these shocks were not all very violent ones, but the first shock was not the only one that had fatal results.

Now, what was the cause of the earthquake? According to the official report of the Central Meteorological Observatory in Tokio, the earthquake seems to have been caused by a subsidence of earth in the south-western part of the Sea of Sagami, with a reaction of a rise of earth in the southern part of the Province of Sagami, including the Miura Peninsula, as well as the Boso Peninsula. The subsidence near Oshima in the Sea of Sagami was between forty and fifty fathoms and there was a corresponding or even greater rise elsewhere. The above-mentioned provinces, including hot spring resorts such as Atami and Miyanoshita as well as sea-side resorts such as Kamakura, Oiso and also the naval station of Yokosuka were the points most affected by earthquake. Yokohama and Tokio, especially the latter, were, comparatively speaking, less affected, so far as the result of the earthquake itself was concerned.

In Tokio and Yokohama, however, the smaller seismic damages were surpassed by the terrible forces of fire, which was directly caused by the earthquake. Owing to the collapse of roofs and ceilings, the cracking of walls and panels, coupled with the breaking down of electric wires as well as the blowing up of gas mains, fire broke out at many different places simultaneously in Tokio and Yokohama. That it was the cooking hour of noon also accounted for the spread of the conflagration, the charcoal fires being overturned, or things turned over them, almost everywhere.

In Tokio, for instance, four places were already on fire at noon,—only a minute or two after the first shock of earthquake, and, in the course of another few minutes fifty-three separate outbreaks were reported. The fire brigades were promptly in action, but their forces were far from being sufficient for such a wholesale conflagration, and it must not be forgotten that the waterworks and mains throughout the city were quickly out of working order. Besides, the wind began to blow hard again, and, from Saturday evening to Sunday, there were twenty-two fresh outbreaks of fire, thus increasing the whole number to no less than eighty-three. The fires which orginated in different parts of the city, eventually joined together and swept over the greater part of Tokio, especially involving the chief business centre of the city. Twelve out of the fifteen wards of the city of Tokio were either wholly or partially on fire, and indeed at some places, where advancing conflagrations met and became one, there arose huge whirlwinds of flame, which added to the horrors of the catastrophe. Moreover, the direction of the wind changed at about 6 o'clock on the Saturday evening, and places which had hitherto been considered safe were brought, in an instant, into the vortex of the advancing fire, and thousands who had thronged to those places in search of refuge now found themselves in the midst of the conflagration, and were burned to death. The most horrible example of this occurred on a large vacant piece of ground in Tokio, where thousands of people had gathered, not only on account of its size, but because the fire appeared to be definitely moving away from it. But when the wind veered round, as I mentioned before, the people were so tightly jammed and packed together that they had no time to make their escape and thirty-thousand hapless souls met their end on that spot. On the other hand, there were cases in which houses that would have been consumed the next moment, owed their salvation solely to this sudden turn in the direction of the wind. Conversely, many who were striving hard to rescue their wives and children who were buried alive under the debris of their houses, were themselves burnt to death together with those they were trying to save. People naturally thought that the bridges over the Sumida, the Thames of Tokio, were among the safest places of refuge, and every one of those bridges was densely packed with hundreds of people. All of the bridges, but one, however, in spite of their iron structure, took fire, and fell, with every soul, old and young, upon them, into the river. The rest needs no telling.

In Yokohama, a portion of the staff of a large Japanese Bank, for example, hurried into the stone building for the purpose of closing the fire-proof shutters, but before they could get out of the building, fire surrounded it and all were roasted to death.

The above are only a few examples of hundreds of thousands of dreadful scenes witnessed in Tokio, Yokohama and elsewhere, and to enumerate more would simply be horrible. One cannot but picture, however, what a pitiful sight it must have been when the survivors, men, women and children, having lost their homes and all or most of their personal effects were huddled in groups, here a few and there a few, in all the safer open spaces, such as the parks or squares, spending night after night in the open air, others wandering about from place to place in grief and in despair, still cherishing the hope of finding their relatives, somewhere, either living or dead! And all these things were happening in the midst of further frequent shocks, great and small, which still froze the hearts of all with terror.

The Imperial Palace in Tokio, which is surrounded by moats, and the Houses of Parliament as well as some Government buildings were saved, while nearly all the large commercial establishments were totally or partially destroyed. Some of the Foreign Embassies and Legations were also damaged. The more hilly part, that is the north western district of Tokio, generally escaped the conflagration. My parents live in that part of Tokio and their house was not in danger, although my mother writes, in one of her letters, that, for about a week, they had no electric light and no gas fire and only a few candles. "But," she continues, "for the first two nights, there was no need of lighting, for, although our house was far from where fires were raging, one could see quite well in the house at night on account of the glare from the burning houses."

In Yokohama, the effect of the earthquake itself was more severe than in Tokio, and nearly the whole city was turned in a day, or one might even say in a few hours, into a scorched field. Here the explosion of oil tanks made things worse and the whole harbour was full of floating oil. By Sunday morning, patches of oil took fire and at one time the flames went up to a height of 200 to 300 feet. The canals, or creeks, as they are called, winding though the city, were also changed into blazing lanes, and people pursued by raging flames on land were flung in their flight into these fiery waterways, and perished. Yokosuka, where there is the well-known naval station and arsenal; Kamakura, famous for its temples and shrines and also as a sea-side summer resort; Oiso, another sea-side resort, Hakoné, the hot spring districts and other places bordering on the sea of Sagami, were all severely damaged. Furthermore, these sea-side places suffered in addition under the visitation of tidal waves, which, however, were not so great as first reported. Any one who has been to Kamakura and its neighbourhood must have visited Enoshima, the island of about 2 miles in circumference near Kamakura. That island was once reported to have entirely disappeared, but this is certainly an exaggeration.

The exact number of casualties is still very difficult to establish. Figures appearing in the latest official report are as follows:—

IN THE CITY OF TOKIO

Dead	67,106
Missing (practically speaking to be assumed all dead) ..	34,536
Injured	41,296

IN YOKOHAMA

Dead	23,440
Missing	3,183
Injured	24,053

Owing to the death of the Prime Minister, Admiral Baron Kato, toward the end of August, the Japanese Cabinet had just tendered its resignation, and when the earthquake came, no new Cabinet had yet been formed. So on the day of the earthquake, outgoing Cabinet Ministers assembled in Council, and, as an emergency measure, the Tokio and the neighbouring afflicted prefectures were at once placed under Martial Law. Count Yamamonto formed a Cabinet the next day in the midst of the burning city; and the first cabinet meeting was held in the open air. Thus, the work of relief and reconstruction was embarked upon. On September 2nd, the Emergency Requisition Ordinance was issued with a view to obtaining the materials and labour necessary for the relief of sufferers in the devastated districts. On the same day, the Provisional

Earthquake Relief Bureau was established under the direct control of the Prime Minister. On September 7th, three further important ordinances were issued; (1) Ordinance regarding moratorium, authorising the postponement of the discharge of private debts for a month, (2) Ordinance prohibiting profiteering and (3) Ordinance forbidding the circulation of alarming rumours calculated to disturb public order or instigate crimes. Several other similar emergency measures were designed and put in practice one after another, such as the exemption or reduction of certain kinds of taxes in favour of earthquake sufferers, temporary abolition of the import duty on rice, necessaries of life, reconstruction materials, etc. A little later, two Government organisations were established, one for the purpose of setting up plans for the reconstruction, and the other for the working out of those plans. In addition to these Government measures, all sections of the whole nation have been displaying activity and have done and are doing much good work for the restoration of trade and the restitution of normal life in the devastated districts. The Emperor lost no time in contributing Y 10,000,000 (about £1,000,000) in aid of the relief of sufferers, an association was organised by eminent business men, members of both houses of Parliament and others, for the purpose of affording facilities to the rescue work, and the Japanese Red Cross Society and other medical and charity associations organised temporary infirmaries and relief corps for the gratuitous treatment of sufferers and the distribution of food and water. The Red Cross, for instance, put up large barracks in the compound of its hospital in Tokio to accommodate 300 sick and wounded and 50 infectious cases, and also in the four most afflicted wards of Tokio for 600 sick and wounded. Similar arrangements were made in other devastated districts outside of Tokio, while in prefectures which were not affected, relief organisations were rapidly made at such places as piers, railway stations, etc., for the refugees who began to arrive from the devastated districts and who increased in numbers from day to day.

The transport of the refugees was wonderfully well carried out by the co-operation of the military and naval authorities on the one hand and steam ship companies and railway authorities on the other. Besides, foreign passenger and cargo ships also did admirable work in this direction. The "Empress of Australia," a Canadian liner, for instance, which was just on the point of leaving the pier of Yokohama for Vancouver, when the earthquake came, took as many refugees on board as she could, both foreign and Japanese alike, and gave them food and drink as well as medical attention, subsequently undertaking their transport to Kobé and further on to Shanghai. The American Oriental Squadron too, afforded wonderful help. The whole fleet which hurried from Chinese waters to Japan, on the timely initiative of the American Ambassador in Tokio, arrived at Yokohama with a large quantity of provisions only four days after the earthquake. Ships also arrived later from America with food, clothing, blankets, building materials, etc. In almost every country throughout the world, a relief fund was promptly started. Here in London, the late Lord Mayor instituted a Mansion House Fund, which realised some £262,000, a great achievement. Their Majesties the King and Queen graciously contributed £500 and £250 respectively, H.R.H. the Prince of Wales also £250. There were also contributions from T.R.H. the Duke and Duchess of York and the Duke of Connaught. Balls and concerts in aid of the relief were organised in London and the country. The Japan Relief Supply Committee was also formed in London by prominent English ladies and gentlemen, and by their efforts, a large quantity of useful things for the immediate use of sufferers have been dispatched to Japan. All this help from foreign authorities and residents in Japan, as well as from abroad, is most appreciated in Japan. The whole nation has regarded so liberal and concrete an expression of sympathy from every part of the world with feelings of profound gratification.

All the means of communication as well as electric, gas and water supply were dislocated by the earthquake, but stringent efforts were made in every direction, and generally a rapid recovery was secured. As regards the electric street tramway of Tokio, for example, the majority of the cars were destroyed by fire, but a certain short section opened traffic as early as September 6, and already toward the end of the third week of that month, the repair of lines was made to the extent that about 500 out of more than 900 surviving cars were in actual service, and it is hoped that by now tram communications in the whole city have become practically normal. The gas supply was also re-established to a satisfactory degree in a comparatively short time. Moreover, the enormous decrease in the power supply consequent upon the loss by fire of some of the gas holders, has balanced the more than corresponding decrease in demand due to the destruction of the busiest part of the city. Out of about 50 electric power stations in Tokio, 30 were placed in working order within a week, and certain restrictions were at first imposed, such as on the number of lamps to be lighted. However, it hardly took ten days before electric lighting in Tokio and its suburbs was brought back almost to its normal state. The postal, telegraph and telephone services were all suspended, but I gather that the first two services have to a great extent been restored, while as to the telephone service, which lost not only the majority of the exchanges in Tokio, but as many as 62,000 apparatuses, communication was possible by the end of a month between only a very limited number of establishments which had direct and important bearings on state affairs and the work of reconstruction and relief. The complete restoration of the telephone system will probably take more than a year. Railway disasters in devastated districts were numerous, owing to the fall of bridges, the collapse of tunnels, viaducts, etc., to say nothing of simple derailings and similar happenings. From September 3rd the unaffected lines and sections were opened for free passenger traffiic, and two days later northbound trains from certain surburban stations were packed with refugees from Tokio, and carried passengers even on the roofs of the carriages. Direct railway connection between Tokio and Western Japan was missing, but one could go up north to a certain point and go down west by the Nakasendo or Midland line, which runs through the Kiso Mountains. Yokohama and other places in, and the east of the Hakone mountains were isolated, and refugees could be carried westward only by sea. The through railway service between Tokio and Kobé was resumed on October 28th, and as before the earthquake, Kobé is now reached from Tokio in less than 13 hours.

Thanks to the extensive emergency repairs carried out in harbour and canal accommodation in Tokio and Yokohama, coupled with the valuable efforts of banking institutions and others interested, the first export of raw silk since the earthquake from the extensively damaged port of Yokohama, took place as early as September 17th.

A matter which needed the most urgent attention, especially in Tokio, was the provision of shelter for homeless people. The Government, while prohibiting the construction of any building of a permanent nature, pending a decision on a new general scheme of town planning for Tokio, authorised by an ordinance the construction of temporary buildings, on which, however, work had to be started before March 1st, 1924, the buildings having to be removed before September 1st, 1928. The Government and the municipal and other authorities lost no time in selecting open spaces, such as public parks and the available ground at shrines, temples and schools, for the construction of temporary wooden barracks. In each of these groups of barracks a certain degree of self-government is allowed to its dwellers, thus giving them the appearance of independent villages. The grounds of some of the Imperial Detached Palaces in Tokio were generally open to the public for this purpose. Temporary wooden shops and offices put up by individual merchants and firms are also rapidly increasing in number—some on their old business sites, and others on sites provisionally acquired. On the other hand, it is interesting to note that shops in some rather out-of-the-way quarters, which were not affected by the earthquake and fire, are now doing a flourishing trade on account of the disappearance of most of the large shops in the more central parts, as well as of the removal of customers to these unaffected districts. That is just what would happen in such places as Finchley Road or Fulham Road, for instance, if all the west end shops suddenly disappeared, and the Mayfair customers were transplanted to North Hampstead or Chelsea!

The destruction of innumerable public schools, too, caused a great deal of anxiety, and open air classes and lectures, are being extensively arranged by the municipalities, by various educational or religious institutions and also by private individuals.

The whole library of the Imperial University was burnt to ashes and the authorities are doing their utmost to replace the books as far as possible, but there were many old documents, manuscripts, etc., for which there are no substitutes in the world, and these can never be replaced. Here in England, the British Museum, the Universities Bureau of the British Empire, the League of Nations Union, and other bodies and institutions have kindly made offers of contributions of books, and over 1,700 valuable volumes have already been received at the Embassy for transmission to Tokio. In addition, on the initiative of the British Academy, under the able and considerate direction of its President, Lord Balfour, an executive committee, representing different learned bodies, including those I have mentioned, and the leading publishers in this country, has been formed in order to centralise efforts in this direction.

In Japan, the ordinary session of Parliament meets every year towards the end of December, the actual business commencing in January, in order to consider, among other things, the budget of the ensuing fiscal year, but last year it was found necessary that a special session should be convoked at the beginning of December for the purpose of considering various emergency measures which the Government had undertaken since the earthquake on its own responsibility, subject to the subsequent approval of Parliament, for the Japanese Constitution recognises such steps as lawful, when, owing to the urgent nature of the matter, the ordinary assembling of Parliament cannot be awaited. This special session had also to consider many material alterations which, in consequence of the catastrophe, had been found necessary in the existing budget for the rest of the current fiscal year. I shall refrain from the enumeration of dry figures, but may perhaps, be permitted to give you some idea of the scope of the work of restoration necessary in the Tokio and Kanagawa Prefectures, of the latter of which Yokohama is the capital. The gross total of the estimated cost for the restoration of Tokio and Yokohama, extending over seven years from 1923 to 1929, which has so far received the approval of Parliament is Y468,438,849. Of that amount, the expenditure on the rebuilding work to be undertaken by the State is Y342,192,800, of which again a little less than 90 per cent. is for the reconstruction of Tokio, and the remainder for that of Yokohama. The above gross total also includes advances to the Tokio and Kanagawa Prefectures of Y15,325,402, and the Government subsidies to these Prefectures, as well as to the cities of Tokio and Yokohama, to the amount of Y89,225,917. Parliament has also passed laws, authorising the Government on the one hand to give guarantees, in case of need, for both the principal and interest of loans which may be issued in foreign markets by the Tokio and Yokohama municipalities to the face value of Y100,000,000 and Y40,000,000 respectively, the Government being permitted, on the other, to issue on its own part in the home market public loans to the extent of Y468,500,000. The Municipalities of Tokio and Yokohama have additional reconstruction work to be executed, on their own account. The gross total of expenditure of the City of Tokio, details of which were laid before its Municipal Assembly by the Mayor of Tokio on December 26th last, is Y182,640,000. A Bill in relation to town planning also passed the Special Session of Parliament and has become law. This, however, refers simply to the organisation and procedure for the execution of town planning in Tokio and Yokohama. The concrete details of those plans are not yet known to me, although they are being worked out vigorously by the organisations concerned and I have seen several tentative proposals or suggestions. Indeed, such details, even if available, would hardly be of interest to you, and the time at my disposal would not allow me to deal with them.

I am afraid I have already trespassed on your patience too long, although, considering the magnitude of the catastrophe as well as the diversity of its consequences, I have found it extremely difficult to condense a review of all the aspects of the subject into a convenient length. In order, therefore, to supplement my insufficient account, I would like to show you some cinema films of the disaster. Some of these were taken by the direction of the Japanese Foreign Office. Others are the property of Mr. Kengo Mori, Financial Commissioner of the Japanese Government in London, who obtained them by the courtesy of the *Osaka Asahi*, a prominent newspaper in Japan. Thanks are due to Mr. Mori for the permission he has so kindly given me for their use this evening.

Before you see the earthquake films, however, I would propose to show you what Tokio looked like before, so that you

may have a more complete idea of the awful effects of the earthquake upon the capital of Japan.

DISCUSSION.

H. E. Baron Hayashi (the Japanese Ambassador) said he was sure the audience, after having listened to the paper, and after seeing the films, had realised the terrible effects of the earthquake which had devastated his country a few months ago. But they had not seen all the effects that night. They had not witnessed the scenes of the people actually dying and actually burning; they had not been able to see the buildings falling down, the railways being broken up, and so forth. Nevertheless, they must have gained an idea of what the consequences of the calamity had been. Those consequences were not those of a war or a revolution. The great destruction which had occurred had all been done in a day, or at the most two days. There was nobody against whom the Japanese nation could protest for such a happening, and that was one reason, he thought, why sympathy and help had been given to the Japanese nation, not only from this country, but from every quarter of the world. Only that morning he had received a letter enclosing a cheque which had come from Newfoundland. He had to confess that he had not been certain where that country was, although it was one of the great Dominions of the British Empire.

He congratulated Mr. Tokugawa on having given the lecture in such a calm and cool manner. Up till about 50 years ago Tokyo was the lecturer's own capital, and the people in it were his own subjects. Nevertheless, without emotion he had been able to give his lecture in the manner in which he had, and he, the speaker, congratulated him on so doing.

The Chairman said he did not think any words of his were necessary to add to the impression which the lecture and the films had made, in varying degrees, upon the minds of the audience. Therefore, he was only going to say "Thank you" to Mr. Tokugawa. He had been amazed at the English in which Mr. Tokugawa had put his thoughts. He did not suppose there was anyone of the British race present that evening, with the possible exception of General Leggett, who could speak Japanese as well as Mr. Tokugawa had spoken English. He thanked the lecturer, in the name of the Royal Society of Arts, and in the name of all those present, for his lecture.

Brigadier-General A. H. Leggett, C.M.G., D.S.O., said that, in rising to second the vote of thanks which had been proposed to Mr. Tokugawa—that illustrious son of a most noble House—he would like to add a few remarks of his own in regard to the films which had been exhibited, and the admirable address which had been given. It must have fallen to the lot of some of those present when residing in far distant lands, and in places where their own language was not often heard, to find some satisfaction and pleasure, and possibly to feel more at home, when someone had spoken to them in their own language. It was in the hope that some of his Japanese friends who were present might experience that pleasure, as he himself had done when residing in some outlying places in Japan, that he proposed to address them, very haltingly he was afraid, in the Japanese language.

(General Leggett then addressed the audience in Japanese.)

By way of explanation he would like to state very briefly what he had tried to convey to their Japanese friends. He had explained that, having been attached to the 29th Regiment of the Imperial Japanese Infantry for a considerable time, he was perhaps in a position to know better than most how the Japanese, in face of great disaster and trial, always met a great calamity. They met it with that calm courage and bravery which was characteristic of their race. He had thanked the lecturer for his admirable address and for showing the films, which had moved the audience all so much. He had ventured to express, too, the deep sympathy of Englishmen throughout the world for Japan and her people in the face of the greatest disaster of its kind which the world had ever known. Further, on behalf of the audience, and on his own behalf, he had ventured to tender their congratulations on the very happy and auspicious event which had occurred recently, namely, the marriage of the Crown Prince of Japan; and lastly, he had tried to express the audience's and his own belief that the Japanese, trusting to the wisdom which they ever derived from the spirits of their ancestors, would, upon the ashes of Yokohama and Tokyo, rebuild even greater and more beautiful cities worthy of the greatness of Japan.

Mr. Tokugawa, in reply, thanked the audience for the very cordial and generous vote of thanks which had just been accorded to him. Some very nice things had been said about his paper, at which he had felt quite overwhelmed; in fact, he was inclined to use the Japanese expression, which might be translated into English as follows: He felt he must find a hole in which to hide himself.

He also had to thank the audience for the very kind attention which they had given to his rather gloomy recital. He would have been much happier if he had been talking about the brighter side of his country. At the same time, the Japanese people were not easily disheartened. Besides that, the devastated region was only a part of Japan—although in many ways a very important part. The industrial centre of Japan, the Osaka district, still stood intact, strong and ready to help to make new Japan still newer and to build it on even stronger foundations. The cherry blossom, the chrysanthemum and the wistaria, unaware of earthquakes, fires and tidal waves,

would continue to bloom peacefully and gracefully as they had bloomed heretofore.

He was sure he was echoing the voice of the gathering that evening when he said that they owed a debt of gratitude to Lord Askwith for presiding that evening. It was indeed a very great pleasure to have had his Lordship as Chairman. He would permit himself, therefore, to propose a most cordial vote of thanks to Lord Askwith.

The vote of thanks was carried unanimously, and the meeting terminated.

LA VIE INDUSTRIELLE EN FRANCE.

◆

Le 25e Anniversaire de la découverte du Radium et l'Institut du Radium, à Paris.

On a fêté solennellement, à la Sorbonne, le 26 décembre dernier, le 25e anniversaire de la découverte du radium, dont la science française est fière à juste titre. C'est, en effet, le 26 décembre 1898, que le Professeur Henri Becquerel présenta à l'Académie des Sciences une note de Pierre Curie et de Marie Curie, son épouse, qu'on peut considérer comme marquant le point décisif des recherches, très longues et très pénibles, de ces savants sur la radio-activité et les corps radio-actifs.

Ces recherches, qui avaient pour point de départ les études d'Henri Becquerel relatives à l'uranium et celles des époux Curie sur le thorium ont abouti, comme on le sait, à l'obtention du radium, en quantités d'ailleurs minimes. On se souvient que les Etats-Unis ont offert, l'année dernière, à Mme Curie, à l'occasion de son voyage en Amérique, un gramme de la précieuse matière, qui a été rapporté à Paris et représente l'une des principales richesses du nouvel Institut du Radium.

Celui-ci, nouvellement construit à Paris, dans le quartier de la Sorbonne, est dirigé au point de vue scientifique par Mme Curie. Il se compose de deux parties : l'une destinée aux recherches de science pure, et l'autre aux applications médicales.

Le jour même où fut célébrée en Sorbonne l'œuvre des Epoux Curie et de leurs savants collaborateurs, notamment M. Debierne, on inaugura le dispensaire de la Fondation Curie, destiné à traiter les maladies relevant du traitement au radium ou "curiethérapie" c'est-à-dire principalement les affections cancéreuses.

Pour reconnaître les grands services rendus à la science par les époux Curie, le Parlement français vient d'accorder, comme il l'avait fait autrefois pour l'illustre Pasteur, une dotation nationale à Mme. Curie, qui consacre toute son activité à cette nouvelle branche de la physique.

Les Nouvelles Locomotives Electriques Express des Chemins de Fer du Midi.

L'électrification des Chemins de fer se poursuit en France sur plusieurs réseaux. Elle est encouragée par le Gouvernement, car elle a l'avantage de réduire les importations de charbon. Le réseau du Midi est celui où l'électrification est la plus avancée. Il utilise à cet effet l'énergie des chutes d'eau des Pyrénées. Après l'expérience de divers systèmes de traction, poursuivie depuis une quinzaine d'années, on a adopté le courant continu à 1,500 volts. La longueur totale des lignes à électrifier est de 3,300 kilomètres (2,050 miles).

Une nouvelle locomotive pour trains express vient d'être soumise à des essais officiels les 28 et 29 décembre. Cette machine attelée à un train de 300 tonnes, atteignit, 3 minutes après le démarrage, la vitesse de 100 kilomètres (62 miles) à l'heure ; peu après, le train roula normalement à 128 kilomètres (79,535 miles) à l'heure. C'est sans doute la plus grande vitesse atteinte en Europe par un train normal.

La locomotive est à deux bogies moteurs identiques ; elle comporte 4 moteurs à ventilation forcée, attaquant les essieux par engrènages ; la puissance totale est d'environ 2,250 h.p.

D'autres machines du même genre, mais moins puissantes, sont en service depuis un an pour la traction des trains de marchandises.

Toutes ces machines sont construites à Tarbes dans une vaste usine installée spécialement pour fabriquer le matériel nécessaire à l'électrification. Cette usine est celle de la Société : Constructions Electriques de France ; on y fabrique aussi des turbines, des dynamos et le matériel des sous-stations. Une autre usine construite récemment dans la même ville, fabrique les isolateurs de porcelaine pour l'équipement des lignes.

Les Essais Controlés d'Automobiles Electriques, à Paris.

Il y a une quinzaine d'années, un certain nombre d'automobiles électriques étaient en service à Paris. Elles ont disparu, parce qu'elles n'étaient pas assez perfectionnées et que les postes de recharge des accumulateurs n'étaient pas assez nombreux.

Pendant la guerre, le manque d'essence a rappelé l'attention sur ce sujet, et les Pouvoirs publics ont encouragé la construction des véhicules électriques. L'année dernière, l'Union des Syndicats d'Electricité, le Laboratoire central de l'Electricité, la Commission technique de l'Automobile Club et l'Office National des Recherches Scientifiques, ont organisé des essais officiels d'automobiles électriques à accumulateurs.

Dix-sept véhicules ont été engagés pour ces essais, qui ont eu lieu en octobre dernier ; onze voitures ont subi toutes les épreuves prévues. La charge utile variait de 250 kgs (550 lbs.) pour les camionnettes ou landaulets, jusqu'à 6 tonnes pour les camions.

Les épreuves ont duré 10 jours, et les véhicules devaient parcourir chaque jour de 50 kilomètres (31 miles) pour les camions, à 80 kilomètres (50 miles) pour les voitures légères. En réalité, la plupart ont parcouru journellement environ 150 kilomètres (93 miles) sur les routes les plus accidentés de la banlieue de Paris.

Les résultats officiels des essais n'ont pas encore été publiés. Les organisateurs ont dû promettre aux constructeurs de ne pas publier de tableau comparatif des performances des diverses voitures. Cependant, nous savons que certains véhicules ont donné des résultats remarquables. Les 3 voitures (camionnettes et coupé) d'une même marque ont fait couramment un parcours journalier de 150 kilomètres (93 miles) sans recharge de la batterie, et avec une consommation de 63 watts-heure par tonne-kilomètre du poids total, et de 275 à 400 watts-heure par tonne-kilomètre utile. En moyenne, la consommation a été de 76 watts-heure à Paris à 80 watts-heure en banlieue par tonne de poids total, pour les camionnettes, et de 60 à 70 watts-heure pour les gros camions.

Ces résultats sont des plus encourageants, et l'on a envisagé l'emploi de voitures électriques pour divers services publics. On étudie même un autobus à accumulateurs pour les transports en commun à Paris.

L'Entrepôt Frigorifique du Port de Bordeaux, a Bassens.

Depuis quelques années, on a installé dans diverses villes de grands entrepôts frigorifiques de denrées alimentaires. C'est ainsi qu'il en existe un dans le port de pêche de Lorient pour le poisson, et un à la gare des marchandises de la Compagnie des Chemins de fer d'Orléans, à Paris. Plus récemment, on a mis en service celui du port de Bordeaux, situé dans l'annexe de ce port créée pendant la guerre à Bassens, sur la rive droite de la Gironde.

Cet entrepôt est particulièrement destiné à recevoir les viandes frigorifiées de l'Amérique du Sud et il forme l'intermédiaire indispensable entre les cargos frigorifiques de la Compagnie des Chargeurs réunis et le réseau ferré de la Compagnie d'Orléans.

Pour réduire au minimum les pertes de froid pendant le transbordement des viandes, le bâtiment est construit près du quai, et lui est relié par un transporteur à courroie sans fin, abrité dans une galerie bien close. La courroie peut transporter des quartiers de bœuf de 300 kilogrammes, à la vitesse de 1 mètre par seconde.

Le bâtiment ne comprend qu'un rez-de-chaussée, de 130 x 57 mètres, divisé en 4 chambres froides d'une capacité de 1,000 tonnes de viande chacune, plus un hall de 2,500 tonnes.

La machinerie frigorifique comprend trois électro-compresseurs, à ammoniaque, donnant chacun 170,000 frigories-heure, et deux réfrigérants d'air pour la ventilation des chambres froides.

Le sol des locaux froids est dallé en liège sur 20 centimètres d'épaisseur, et les parois et plafonds sont également en briques de liège, avec couche de liège granulé de 30 centimètres.

CORRESPONDENCE.

THE SURVEY OF INDIA.

I have read with great interest the paper entitled "The Survey of India" by Col. H. L. Crosthwait, and I have particularly noticed his reference to the great weight of the mountain mass of the Himalayas, and I was reminded of a book by Prof. Joly of Dublin, who considers that the elevation of the Himalayas is due to the action of radium.

If Col. Crosthwait would deal with Prof. Joly's theories, it would be instructive to some of us.

Arnold Lupton.

NOTES ON BOOKS.

Electrical Engineering Practice. By J. W. Meares and R. E. Neale. Fourth Edition, Vol. I. London: Chapman and Hall, Ltd. 25s. net.

The characteristics which have made previous editions specially valuable to the practical man, are well to the front in the first volume of the fourth edition. These features are:—Many details and much instruction in few words, and the production of something comparable to a technical pocket-book, but on a very much larger and more complete scale; and recognition of the fact that a verbal definition or expression cannot always be indubitable in its meaning, but often requires an example or a graphic illustration.

By the application of such principles of construction or arrangement as are indicated above, the authors give us the first volume of a two-volume treatise on practical electrical engineering, which represents a concentrated aspect of the electrical practice of to-day. Vol. I embodies nearly 600 large octavo pages with many plates and 92 illustrations in the text. This new edition will more than maintain the reputation of the earlier editions.

It is somewhat disconcerting to read (p. 150), that supply meters have been and still may be in use, which by reason "of the gear wheels being only friction-tight on the spindles, may occasionally slip a notch and give a reading 10, 100, or 1000 units in excess."

The Divinity School, Oxford. By H. Edith Legge. With fifty-four illustrations. Oxford: Basil Blackwell. 2s. net.

This book, modestly described as a guide for visitors, is really a survey of the building, with special reference to the famous sculptured ceiling, and forms a valuable work of reference. It contains a large amount of information on every detail of the carvings, presented in a concise and readable manner.

Even apart from the letterpress, the book is well worth securing for the admirable illustrations, which reproduce the details of the sculptures with great fidelity, and are extremely useful for detailed study. In fact, one can appreciate the carvings better from such photographs than by examination of the originals in the ordinary way available to visitors.

The general get-up of this guide book (and the very modest price) might well be taken as a model

by those who publish similar guides to other historic buildings.

N.H.

DECORATIVE FURNITURE. By George Leland Hunter. Philadelphia and London: J. B. Lippincott Company; Grand Rapids: Good Furniture Magazine. £5 5s. net.

This handsome volume should be joyfully welcomed by the student and the collector of furniture. Modestly described by the author as "a picture book of the beautiful forms of all ages and all periods" it gives examples in chronological order of furniture including Egyptian, Assyrian, Greek, Roman, Byzantine, Chinese, Japanese, Persian, Romanesque, Gothic, French Renaissance, Italian Renaissance, Later Italian, Louis XIII, XIV, XV, XVI, Directoire and Empire, Spanish, Portuguese, Flemish, Dutch, Swiss, Elizabethan, Jacobean, Charles II., William and Mary, Queen Anne, early Georgian, Chippendale, Adam, Hepplewhite, Sheraton, American Colonial, modern European and American, and American Mission. The book contains over 900 illustrations, with 23 coloured plates. Every page is a delight, and should be a fruitful source of inspiration to the designer of furniture. The specimens selected, whether single chairs, chests or tables, or completely furnished rooms, are admirable, and the manner in which the illustrations are reproduced leaves nothing to be desired.

A good many very fine specimens of panelling and other woodwork are now in America, and it is interesting to notice the effect that they have produced on modern American furniture. Particularly beautiful are the rooms modelled on the Italian Renaissance style by Charles A. Platt and the late Stanford White, while much of the American Colonial and Mission furniture, though clearly inspired by older styles, has an individuality and charm all its own.

The letterpress is wisely made subordinate to the illustrations, but it suffices to give in small space a competent account of the various periods dealt with. Mr. Hunter confesses to a personal preference for the furniture of the Italian Renaissance above that of any other period; this preference, however, does not prevent him from doing justice to all, and he writes with a very full knowledge of a vast subject.

It is not too often that one comes across a work that gives such unqualified satisfaction to the reader, and one feels that a deep debt of gratitude is due alike to the author, the publishers and the printers, for the care that they have lavished in producing this work.

THE LIBRARY.

The following books have been presented to the Library since the last announcement. Except where otherwise stated, they have been presented by the publishers:—

Abell, Sir Westcott, K.B.E. The Ship & Her Work. London: Gee & Co., Ltd., 1923.

Allen, Robert, M.A., B.Sc.—Copper Ores. London: John Murray. 1923.

Aspinall, Algernon, C.M.G.—Pocket Guide to the West Indies. London: Sifton, Praed & Co., Ltd. 1923.

Beauchamp, J. W.—Industrial Electric Heating. London: Sir Isaac Pitman & Sons, Ltd. 1923.

Belaiew, Col. N. T., C.B.—Crystallisation of Metals. London: University of London Press, Ltd.

Berger, J. A.—Executorship and Death Duties. London: Solicitors' Law Stationery Society, Ltd. 1923.

Blacker, J. F.—The A.B.C. of English Salt-Glaze Stoneware. London: Stanley Paul & Co. 1922. Presented by H. L. Doulton, Esq.

Bolton, D. J., B.Sc.—Electrical Measuring Instruments & Supply Meters. London: Chapman & Hall, Ltd. 1923.

Brendon, J. A., B.A.—Britain & Her Neighbours. Book VII. The Twentieth Century. London: Blackie & Son, Ltd. 1923.

British Journal Photographic Almanac, 1924. London: Henry Greenwood & Co., Ltd.

Burnham, Thos. H.—Special Steels. London: Sir Isaac Pitman & Sons, Ltd. 1923.

Butler, Howard Russell.—Painter and Space. New York: Charles Scribner's Sons. 1923.

Campbell, Persia Crawford, M.A.—Chinese Coolie Emigration. London: P. S. King & Son, Ltd. 1923.

Carter, E. Ellin.—Designs for Artistic Leather Work. Part I. London: E. & F. N. Spon, Ltd. 1923.

Carter, Howard & A. C. Mace.—The Tomb of Tut-Ankh-Amen. Vol. I. London: Cassell & Co., Ltd. 1923.

Conradi, Charles Guthrie, M.I.Mech.E.—Mechanical Road Transport. London: Macdonald & Evans. 1923.

Conway, Sir Martin, M.P.—The Van Eycks and their Followers. London: John Murray. 1921.

Dalton, Hugh, M.A., D.Sc.—Principles of Public Finance. London: George Routledge & Sons, Ltd. 1923.

Daniel, Percy P.—Hints for a Company Secretary. London: J. M. Ouseley & Son, Ltd.

Ellis, David, D.Sc.—A Science Course for Bakers. London: Blackie & Son, Ltd. 1923.

Fellows, E.—Colour: Charted and Catalogued. London: "Geographia," Ltd.

Fox, Cyril S., B.Sc., F.G.S.—Civil Engineering Geology. London: Crosby Lockwood & Son. 1923.

Gibbs, R. W. M., B.A., B.Sc.—Technical Arithmetic. London: Blackie & Son, Ltd. 1923.

Groves, E. J. A., Lic. ès L.—A Preparatory French Course. London: Blackie & Son, Ltd. 1923.

Hall, B. J., M.I.Mech.E.—A System of Plan Copying in Black Lines. London: Sir Isaac Pitman & Sons, Ltd. 1923.

Henri, Robert.—The Art Spirit. London: J. P. Lippincott Company. 1923.

Hervey, Mary F. S.—Holbein's "Ambassadors." London: George Bell & Sons, 1900. Presented by Miss Phillimore.

Hewitt, J. T., M.A., D.Sc., F.R.S.—Dyestuffs derived from Pyridine, Quinoline, Acridine & Xanthene. London: Longmans, Green & Co. 1922.

Hodgkinson, Thomas W.—The Director System for Cutting Ladies' Garments. Second Edition. London: Minister & Co., Ltd.

Hunter, George Leland.—Decorative Furniture. Philadelphia and London: J B. Lippincott Company.

Hyde, J. H.—Lubrication & Lubricants. London: Sir Isaac Pitman & Sons, Ltd. 1922.

Jamieson, Prof. Andrew.—A Text-Book of Heat and Heat Engines. Vol. 2. Eighteenth Edition. Rewritten by Ewart S. Andrews, B.Sc. London: Charles Griffin & Co., Ltd. 1923.

Jennings, Arthur Seymour.—The Decoration & Renovation of the Home. London: W. R. Howell & Co. 1923.

Jordan's Tabulated Weights of Iron & Steel. Eighth Edition. London: E. & F. N. Spon, Ltd. 1923.

Kaye, G. W. C., O.B.E., M.A., D.Sc.—X Rays. London: Longmans, Green & Co. 1923.

Lees-Smith, H. B., M.A., M.P.—Second Chambers in Theory and Practice. London: George Allen & Unwin, Ltd. 1923.

Lethaby, W. R.—Londinium—Architecture & the Crafts. London: Duckworth & Co. 1923.

Loring, F. H.—The Chemical Elements. London: Methuen & Co., Ltd. 1923.

Lovell, R. Goulburn, A.R.I.B.A.—Courage in Colour. London: Charles Griffin & Co., Ltd. 1922.

Macara, Sir Charles W., Bt.—The New Industrial Era. Manchester: Sherratt & Hughes. 1923.

Manning, Frederick.—Life of Sir William White, K.C.B., F.R.S. London: John Murray. 1923.

Marsh, Lewis, M.A.—A First Book of Literary Reading & Composition. London: Blackie & Son, Ltd. 1923.

Martin, L. C., D.Sc., and William Gamble.—Colour and Methods of Colour Reproduction. London: Blackie & Son, Ltd. 1923.

Meares, J. W., C.I.E., and R. E. Neale, B.Sc.—Electrical Engineering Practice. Vol. I. Fourth Edition. London: Chapman & Hall, Ltd. 1923.

Mitchell, C. Ainsworth, M.A.—The Expert Witness. Cambridge: W. Heffer & Sons, Ltd. 1923.

THE BACON-CURING PIG.

Writing in the *Journal of the Pig Breeders' Scientific Society*, Mr. Loudon M. Douglas, F.R.S.E., states that the weight to which a pig may be allowed to grow for bacon purposes has been modified within recent years. In the old days it was customary to fatten a pig for bacon curing up to 18 or 20 score; and in this way supply the household with fat bacon which lasted throughout the winter. Now, however, people refuse to eat fat, and, as a consequence, the weight of the bacon pig has been fixed at something around 200lbs. live weight. The live weight may be taken as being

20 per cent. above the carcase weight, on the average; and this again may be taken as 20 per cent. above the bacon weight, provided that Wiltshire sides are cured. But it is quite easy to regulate the weight to about 200lbs. live weight, as the pig is the most adaptable of any of the animals on the farm, and it may also be said to be the most profitable, as it increases its weight by one hundredfold or more in six months. The 200lb. pig has the enormous advantage of being just sufficiently supplied with fat, and a fair standard may be taken as 1½ inches to 1¾ inches of fat down the back. If this proportion is maintained it will be found that the percentage of lean in the meat is just what is wanted by the average customer.

There are, unfortunately, a great many different types of pigs in the United Kingdom. We have some 13 pure breeds, and as time goes on we are threatened with several more, which will add to the confusion of the whole subject of the bacon curer's pig. For, after all, what the bacon curer wants is not any particular breed of pig, but one which will show him properly-balanced fat and lean and a relatively small proportion of bone to flesh. It is quite useless for pig breeders' societies to lay down points for the particular breeds which they fancy, giving rates of value to the tail and the ears, and such features as do not interest the bacon curer at all. The principal part of the pig, so far as the bacon curer is concerned, is the loin and the hams. The public demand is for streaky bacon from the flanks; and some of the breeds of pigs which are much spoken of at the present day are absolutely without this feature. It would, therefore, seem that the time must arrive if we are to make any great progress in pig breeding in the United Kingdom, when the big breeders must try to reduce the number of breeds of pigs instead of trying to add to them, as at present. We have, surely, a sufficient inducement to devote our energies to the proper kind of bacon pig when it is remembered that we in this country spend in overseas countries £1,000,000 per week in bacon, hams, and cognate pig products; and it is quite idle to say that this cannot be altered, as we have in this country every possible condition which would contribute to the development of a large pig industry. We also have many bacon factories where bacon curing is carried on, sometimes with great difficulty, owing to the absence of a proper supply of pigs, notwithstanding the fact that British cured bacon commands the highest price of all the bacon consumed in Great Britain, very often being 20s. per cwt. higher in value than all other imported kinds.

How to obtain this bacon pig is, of course, the principal question, and there are many people who have given a great deal of attention to the subject during recent years. Generally speaking, it may be laid down that the bacon pig can be produced from any of the pure breeds. It is purely a question of selection and feeding. It is also pretty generally accepted that the first cross of some of the pure breeds gives a more satisfactory bacon pig than any other. Thus a cross between a Large Black sire and a Large White sow gives an excellent bacon pig. It very much depends upon the sire, and it is in this particular respect that purity of breed becomes of value. It has been shown by direct experiment that the pure-bred sire will give an increase of 40 per cent. over the stock produced by an ordinary boar; and such a fact goes to prove that the selection of sires is really one of the principal businesses in connection with the production of bacon pigs.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 27.—CHARLES S. MYERS, C.B.E., M.D., Sc.D., F.R.S., Director, National Institute of Industrial Psychology, "The Use of Psychological Tests in the Selection of a Vocation." SIR ROBERT BLAIR, LL.D., Education Officer, London County Council, will preside.

MARCH 5.—MAJOR-GENERAL SIR FABIAN WARE, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

MARCH 12.—ALAN A. CAMPBELL SWINTON, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.) SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., will preside.

MARCH 19.—R. L. ROBINSON, Member of the Forestry Commission, "The Forests and Supply of North America." LORD LOVAT, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., will preside.

MARCH 26.—NEAL GREEN, "The Fishing Industry and its By-Products." PROFESSOR E. W. MACBRIDE, D.Sc., F.R.S., will preside.

APRIL 2.—SIR LYNDEN MACASSEY, K.B.E., "London Traffic."

APRIL 9.—FRANK HOPE-JONES, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." PROFESSOR C. VERNON BOYS, F.R.S., will preside.

APRIL 30.—BRIGADIER-GENERAL SIR HENRY MAYBURY, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "Roads."

May 7.—J. Robinson, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

May 14.—

May 19 (Monday).—Sir James Fortescue-Flannery, Bt., Ex-President, Institution of Marine Engineers, "Marine Internal Combustion Engines." The Rt. Hon. Lord Bearsted will preside.

May 21.—Professor C. Vernon Boys, F.R.S., "Calorimetry." (Trueman Wood Lecture.)

May 28.—Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Date to be hereafter announced:—

T. Thorne Baker, "Photography in Industry, Science and Medicine."

Indian Section.

Friday afternoons at 4.30 o'clock:—

March 21.—Otto Rothfeld, I.C.S., "Progress of Co-operative Banking in India."

May 2.—Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced:—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

Dominions and Colonies Section.

Tuesday afternoons at 4.30 o'clock:—

March 4.—The Hon. T. G. Cochrane, D.S.O., "Empire Oil: The Progress of Sarawak." The Rt. Hon. Lord Bearsted will preside.

May 27.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Cantor Lectures.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

Syllabus.

Lecture I.—February 25.—The carbonisation of coal considered as a process for distributing the thermal energy of the coal into therms in the form of gas, tar and coke. Factors which cause wastage of therms in the form of gas and the principles underlying high yields of gaseous therms.

Lecture II.—March 3.—The inter-relation of therms in the form of gas and tar and the process conditions which affect their distribution. Further principles underlying high yields of gaseous therms. The chemistry and economics of tar cracking.

Lecture III.—March 10.—The trend of developments in carbonising processes. The de-ashing of coal and other factors tending to increase the value of the therm in the form of coke.

Cobb Lectures.

Monday evenings, at 8 o'clock:—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, February 25 ... Geographical Society, 135, New Bond Street, W., 8.30 p.m. Mr. L. Koch, "Northward of Greenland."

University of London, University College, Gower Street, W.C., 5.30 p.m. Sir Harry Stephen, "Criminal Law." (Lecture I.)

At King's College, Strand, W.C., 5.30 p.m. Rev. C. F. Rogers, "Ecclesiastical Music." (Lecture IV.)

5.30 p.m. Dr. R. W. Seton-Watson, "A Survey of Bohemian History." (Lecture IV.)

At the Institution of Civil Engineers, Great George Street, S.W., 5 p.m. Mr. O. C. A. Van Lidth De Jende, "Practical Hydraulic Engineering Problems in connection with Navigation." (Lecture I.)

Tuesday, February 26 ... Automobile Engineers, Institution of, at the Royal Society of Arts, John Street, Adelphi, W.C., 6.30 p.m. Mr. H. K. Thomas, "The Fundamentals of Cost Reductions."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Miss Gladys Pott, "Migration of Women within the Empire."

Photographic Society, 35, Russell Square, W.C., 7 p.m. (Kinematograph Group). Papers on the mechanism of the Cine camera, "The Intermittent Motion," "Front Gadgets and Trick Mechanism," "Focusing Devices."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. L. Rothera, "Electricity as the Motive Power for Ships."

Economics and Political Science, London School of, Houghton Street, W.C., 6 p.m. Sir Edward Grigg, "The Problem of Imperial Organisation."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. J. Barcroft, "The Respiratory Pigments in Animal Life." (Lecture III.)

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m.

(Joint Meeting with the Society of Chemical Industry.) Papers on "The Treatment of Water for Industrial Purposes."

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. J. H. Helwig, "Modern Danish Lyrics, 1870—1920." (Lecture IV.)

5.30 p.m. Mr. N. H. Haynes, "The Roman Empire and its Invaders." (Lecture IV.)

At King's College, Strand, W.C., 5.30 p.m. Sir Bernard Pares, "Russia before Peter the Great to 1861." (Lecture VI.)

5.30 p.m. Dr. H. W. Carr, "The Transition to the Relativist Conception of Nature." (Lecture IV.)

At the London School of Economics, Houghton Street, W.C., 5 p.m. Prof. A. P. Brigham, "The Geography of the United States, Regional and National." (Lecture II.)

WEDNESDAY, FEBRUARY 27 ... London County Council, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Sir Napier Shaw, "An Introduction to Modern Meteorology." (Lecture I.)

Literature, Royal Society of, 9, Bloomsbury Square, W.C., 5 p.m.

Brewing, Institute of (Midland Counties' Section), Burton-on-Trent. Prof. H. E. Armstrong, "Humour and its Potency—a Character Study."

British Academy, at the Royal Society, Burlington House, Piccadilly, W., 5 p.m. Dr. J. W. Mackail, "Bentley's Milton." (Warton Lecture on English Poetry.)

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. H. G. Williams, "Foreign Exchange, its Effects on Industry and Cost of Living."

Microscopical Society, 20, Hanover Square, W., 7 p.m. (Section in the Industrial Application of the Microscope.) 1. Mr. R. Daubney, "Notes on some Parasitic Worms of Importance to Agriculturists." 2. Mr. H. J. Denham, "Practical Microscopy in Research on Textile Fibres." 3. Mr. J. E. Barnard, "Technical Microscopy."

Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Mr. W. B. Wright, "Age and Origin of the Lough Neagh Clays."

Japan Society, Victoria and Albert Museum, South Kensington, S.W., 3 p.m. Lieut.-Colonel E. F. Strange, "The Incense Ceremony."

Automobile Engineers, Institution of, 244, Deansgate, Manchester, 6.30 p.m. Mr. P. Pritchard, "Modern Foundry Practice."

University of London, University College, Gower Street, W.C., 3 p.m. Prof. E. G. Gardner, "Problems of the Inferno." (Lecture VI.)

5.30 p.m. Prof. Geyl, "English Diplomacy in Holland in the XVIII. Century." (Lecture III.)

5.30 p.m. Mr. I. C. Grøndahl, "Contemporary Norwegian Literature." (Lecture IV.)

5.30 p.m. Mr. R. A. Peddie, "Printing Presses and Machinery from the Earliest Times and their Influence on the Book and Newspaper."

6 p.m. Prof. Karl Pearson, "The Current Work of the Biometric and Eugenics Laboratories." (Lecture III.)

At King's College, Strand, W.C., 5.30 p.m. Mr. B. Rackham, "The Artistic Background of Mediæval History—Glass and Pottery."

At the Royal College of Music, South Kensington, S.W., 5 p.m. Sir Henry Hadow, "English Composers of the Tudor Period." (Lecture I.)

At the Institution of Civil Engineers, Great George Street, S.W., 5 p.m. Mr. O. C. A. Van Lidth de Jende, "Practical Hydraulic Engineering Problems in connection with Navigation." (Lecture II.)

THURSDAY, FEBRUARY 28 ... Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6.30 p.m. Mr. A. E. Cooper, "The Requirements of Motor Delivery Vans."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

British Decorators, Institute of, Painters Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. A. Orr, "A Tour in Spain with the Incorporated Institute of British Decorators."

Auctioneers and Estate Agents Institute, 34, Russell Square, W.C., 7.30 p.m. Mr. W. S. Edgson, "The Valuation of Shop Property."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C. 6 p.m. Mr. A. S. Fitzgerald, "The Design of Apparatus for the Protection of Alternating Current Circuits."

London County Council, Geffrye Museum, Kingsland Road, E., 7.30 p.m. Mr. H. A. Tipping, "Furniture—The Dining Room from the Earliest Times to the Present Day." (Part II.)

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. Sir W. Bragg, "Crystalline Structure of Organic Substances." (Lecture IV.)

Mechanical Engineers, Institution of (North-Western Branch), Engineers Club, Manchester, 7 p.m. Mr. J. E. Hurst, "Engineers' Inventions and Patents."

University of London, University College, Gower Street, W.C., 5.30 p.m. Signor C. Pellizzi, "Campanella."

5.30 p.m. Mr. L. Björkhagen, "Modern Swedish Prose Authors." (Lecture IV.)

5.15 p.m. Prof. J. E. G. de Montmorency, "Comparative Law of Europe and Asia." (Lecture VI.)

At King's College, Strand, W.C., 5.30 p.m. Dr. A. R. Pastor, "Spanish Mysticism." (Lecture I.)

5.30 p.m. Prince D. S. Mirsky, "The History of Russian Literature." (Lecture VI.)

At St. Mary's Hospital Medical School, Praed Street, W., 5 p.m. Prof. B. J. Collingwood, "Blood." (Lecture II.)

At St. Thomas's Hospital, Albert Embankment, S.E., 5 p.m. Dr. J. A. Murray, "Cancer." (Lecture II.)

At the London School of Economics, Houghton Street, W.C., 5 p.m. Dr. J. H. Clapham, "Britain on the Eve of the Railway Age." (Lecture II.)

FRIDAY, FEBRUARY 29 ... Royal Institution, Albemarle Street, W., 9 p.m.

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. T. A. Scotton, "The Making of a Railroad Locomotive."

Auctioneers and Estate Agents Institute, 34, Russell Square, W.C., 11.30 a.m. Conference of Agricultural Members. 2.30 p.m. Mr. A. W. Merry, "Practice under the Agricultural Holdings Act, 1923, in the light of recent Legal Decisions."

University of London, King's College, Strand, W.C., 5.30 p.m. Prof. R. W. Seton-Watson, "The Rise of Nationality in the Balkans." (Lecture VI.)

5.30 p.m. Dr. H. Lamb, "The Internal Constitution of the Earth." (Lecture III.)

At the London School of Economics, Houghton Street, W.C., 5 p.m. Prof. A. P. Brigham, "The Geography of the United States, Regional and National." (Lecture III.)

At the Institution of Civil Engineers, Great George Street, S.W., 5 p.m. Mr. O. C. A. Van Lindth de Jende, "Practical Hydraulic Engineering Problems in connection with Navigation." (Lecture III.)

SATURDAY, MARCH 1 ... Royal Institution, Albemarle Street, W., 3 p.m. Mr. W. De La Mare, "Character in Fiction."

London County Council, Horniman Museum, Forest Hill, S.E., 3.30 p.m. Mr. H. N. Milligan, "Animals which live in Trees."

Journal of the Royal Society of Arts.

No. 3,719. VOL. LXXII.

27. MAR 1924

FRIDAY, FEBRUARY 29, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

Monday, March 3rd, at 8 p.m. (Cantor Lecture.) **Edward Victor Evans**, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." (Lecture II.)

The Lecture will be illustrated with a cinematograph film showing the decomposition of cyclohexane by heat.

Tuesday, March 4th, at 4.30 p.m. (Dominions and Colonies Section.) **The Hon. T. G. Cochrane**, D.S.O., "Empire Oil: The Progress of Sarawak." **The Rt. Hon. Lord Bearsted** will preside.

Wednesday, March 5th, at 8 p.m. (Ordinary meeting.) **Major-General Sir Fabian Ware**, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

ELEVENTH ORDINARY MEETING.

Wednesday, February 20th, 1924; **Sir Stanley Bois**, late Chairman of the Ceylon Chamber of Commerce, in the Chair.

The following candidate was proposed for election as a Fellow of the Society :—

Bone, Stephen, London.

The following candidates were duly elected Fellows of the Society :—

Elston, Frederic, London.
Mant, Sir Reginald Arthur, K.C.I.E., C.S.I., London.
Smith, Frederick Richard, Hampden-in-Arden.
Young, Brig.-General Henry Alfred, C.I.E., C.B.E., Exmouth.

A paper on "New Uses for Rubber" was read by **Mr. Percival James Burgess**, M.A., F.I.C., Chairman, Rubber Growers' Association.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES SECTION.

Tuesday, February 5th, 1924.

Sir George R. Le Hunte, G.C.M.G., formerly Lieut.-Governor of British New Guinea, in the Chair.

The Chairman, in opening the meeting, said he regretted very much that owing to the time of the meeting he would have to leave before the end, to catch his train. He wished to express his great pleasure at meeting his old friend the lecturer, Mr. Walker, whom he had known so well in New Guinea on the staff of the London Missionary Society. He knew of Mr. Walker's good work. He had had the opportunity of reading a draft of the paper, and he thoroughly agreed with what Mr. Walker said in it with reference to the native races generally and with regard to New Guinea in particular.

The paper read was :—

THE COMMERCIAL FUTURE OF THE BACKWARD RACES.

By F. W. **Walker**,

Managing Director of the Papuan Industries, Ltd.

I am grateful to the Royal Society of Arts for giving me the opportunity of addressing you on this subject, which is one of great and growing importance to the British Empire.

I am especially grateful to Sir George Le Hunte for consenting to preside on this occasion. It is one more proof of his deep and abiding interest in the welfare of native races, of which he has given many during his long and distinguished career. The British Empire owes much to such men as he, who have maintained our honour and upheld our high traditions in positions of great responsibility in the remote parts of the Empire.

I was in New Guinea during the whole of Sir George's term of office as Lieutenant-Governor so I can speak from first-hand knowledge, and I can assure you, and I can assure him, that he is remembered with deep gratitude by all those who have the interest of the natives at heart.

British New Guinea, or to be strictly correct, British Papua, which first became a Crown Colony in 1888, and was handed over to the Commonwealth of Australia in 1906, has been particularly fortunate in its Governors. It must not be confused with what was formerly German New Guinea, which is quite a separate territory and has a Governor of its own with headquarters at Rabaul in New Britain.

The first Governor of British Papua was Sir William MacGregor, who was an exceptional man in every way. By him the foundations of the Constitution were well and truly laid with great wisdom and foresight. I think I am correct in saying that for the first time in the history of the British Empire, the sale of drink and firearms to natives was prohibited from the start, under heavy penalties, and these laws have been strictly and successfully enforced right up to the present day, with incalculable benefit to the natives, as Sir George can testify.

The present Governor, the Hon. J. H. P. Murray, a brother of Prof. Gilbert Murray, is not one whit behind his great predecessors in his regard for and interest in the welfare and progress of the natives, and if he is spared to carry out his ideas, of which I shall have more to say later on, he will confer an immense and enduring benefit upon Papua.

Favoured with such a striking succession of great pro-consuls as the late Sir William MacGregor, Sir George Ruthven Le Hunte, and the Hon. J. H. P. Murray, and with the two great curses of native races, drink and firearms, excluded, the outlook for the natives of Papua is surely a hopeful one, provided men of like spirit can be found to carry on this great succession.

In order to secure this very desirable result it is necessary that public opinion at Home should be educated and informed, so that men of this high type shall be adequately supported in their great endeavours to uplift these primitive peoples.

THREE POLICIES.

Canon Elliott, of Leicester, speaking last year at the London Rotary Club, said:—"The first policy of the white man with regard to the Backward Races was to exterminate them, the second policy has been to exploit them; now it is to be hoped that we are going to recognise that the wisest and best policy of all is to uplift and help them."

This last policy needs widespread public support if it is to be effectively carried out. It is on behalf of this policy that I wish to plead to-night. The question we have to consider is, how are we to secure a future of progress and usefulness for the Backward Races? What policy must we adopt with regard to them which is in their best interests—because that is the policy which is in the best interest of the British Empire and also of the world in general.

A great responsibility rests upon us in this connexion, as we have more of these Backward Races under our care than any other Empire that has ever existed, and it is impossible to exaggerate the importance of a right policy with regard to them.

A PROBLEM IN ECONOMICS AND ETHICS.

This is essentially a problem in Economics, but because the prime factors in the case are men and not machines or inanimate matter, it is a problem which cannot be successfully solved apart from Ethics. That type of Political Economy which ignores the human element has been utterly discredited by the experience and progress of modern times. The evidence of this is seen in the rapid spread of various welfare movements and in the success of numerous schemes of co-partnership and profit-sharing and similar developments of recent years. Whatever our views may be with regard to these developments, they are a clear indication of the recognition of the fact that ethical considerations can no longer be ignored if the wheels of industry are to run smoothly, and while this is the case here in England it applies with equal force to industrial developments abroad. The mere fact that in the one case the labour is white and in the other case it is black, does not make any essential difference. In both cases the labour is human and the principles involved are the same. In a word, the demand for justice cannot be admitted in the case of the white man and denied in the case of the coloured man.

DANGER OF COLOUR PREJUDICE.

The study of history clearly reveals that "There is a Power, not ourselves, which makes for righteousness," and if we are not prepared as an Empire to be scrupulously just and impartial in the shaping of our policy with regard to the subject races committed to our care, retribution will surely fall upon us, as it has fallen upon other Empires which made a wrong use of their power. The "mills of God grind slowly," but iniquity cannot escape their grinding, however long it may be deferred. Those who refer to the coloured races with contempt as "niggers" and sneer at any suggestion to secure for them a fair opportunity for development and progress are the most dangerous enemies of the British Empire, for they are "enemies within the gate." The enemies outside we have always been able to deal with successfully, but these enemies in our midst constitute a more insidious danger, and I for one regard them with no small anxiety, for they are financially strong and powerful, and unless the great spirit of the nation asserts itself they will work their will upon these Backward Races with disastrous results to all concerned.

Without sympathy and understanding it is impossible for men, white or black, to pull together. If these elements are not cultivated, war, with all its waste and misery, is inevitable.

Basil Mathews brings this point out very clearly in his foreword to a pamphlet by Harold Begbie on "Christianity and Commerce," recently published.

Mr. Mathews writes :—

"'The black will never understand the white, nor the white the black, as long as black is black and white is white,' argues Captain Woodward, the South Sea labour recruiter, one of Jack London's heroes in his 'South Sea Tales.' The talk is going on in the parlour of the 'pub' at Apia, the greatest harbour of the Samoan Islands.

"'A friend retorts vigorously: 'If the white man would lay himself out a bit to understand the workings of the black man's mind most of the messes would be avoided.'

"This provokes Captain Woodward, who thereupon breaks out into a long, vehement reply, in which he says: 'Don't talk to me about understanding the nigger. *The white man's mission is to farm the world, and it's a big enough job cut out for him. What time has he got left to understand niggers, anyway?'*

"And the worthy captain follows his moral with a story of labour-recruiting, which issues in a murderous attack by recruited natives, followed by a cold blooded massacre by a white man with two rifles and inexhaustible ammunition.

* * *

"That conversation and that story sum up in one picture the tragic, dramatic contest of those two ideas of exploitation on the one hand and understanding on the other—not only in the South Seas, but in the whole world wherever the white man has come into contact with 'the backward races.'

"The story during the last four centuries of the white man's expansion into America, India, Africa, Australasia, and Polynesia, indeed, has proved that—for that period of human history, at any rate—it has been 'the white man's mission to farm the world.' And in his indomitable and often ruthless will to 'farm the world' the white man has often, on the one hand, mown down the races that opposed him, and, on the other, yoked to his service those who did not. The dying out of the Red Indian, the growth of the African slave trade with America, the extermination of the Tasmanians, the foul record of the Kanaka traffic in the South Pacific, are all part of a story of infamous wrong that—in total—represents the blackest stain on the world record of the white races."

We may admit the truth of these words but some may be disposed to comfort themselves with the thought that these things belong to a past age.

Do not let us live in a "fool's paradise." All unscrupulous and ruthless white men are not dead. They are perhaps a little more discreet in these days, more careful not to "give themselves away," but they are still amongst us in considerable force watching for opportunities, and to them the ignorant and defenceless "nigger" dwelling in lands of great wealth and future possibilities is "fair game." If you suggest that the said "nigger" should be enlightened and taught and assisted to develop his own land for his own benefit they are immediately up in arms and accuse you of "spoiling" these people and from their point of view such a policy will undoubtedly "spoil" them. Many good people living quietly at home in England have little idea of what is going on in many of these tropical lands at the present day. If any persons want information on these points let them apply to the Anti-Slavery and Aborigines Protection Society, whose records contain much startling evidence of the need for constant watchfulness in connexion with these matters.

Quite recently that Society brought to light two cases where natives were flogged to death by white planters in different parts of Africa, the one in Kenya and the other in Rhodesia, less than a year ago.

I quote these cases to show that we have still this kind of white man in our midst, and, unfortunately, he is not as rare as many suppose.

IMPORTANT WORK OF THE ANTI-SLAVERY SOCIETY.

In passing, permit me to say we have every reason to be grateful to a Society which keeps a watchful eye on this type of Britisher. Many people seem to imagine that the work of the Anti-Slavery Society was practically completed when slavery was abolished in 1836, but that is a great mistake. The full title of the Society is "The Anti-Slavery and Aborigines Protection Society," and their splendid work in connexion with the Congo and Putumayo atrocities, only to mention two great instances, is evidence of the great need of their activities in later times. A more recent and no less striking instance of their usefulness is in connexion with the question of slavery in Abyssinia, which still exists there almost unnoticed, on an immense scale. But apart altogether from these great outstanding instances of their usefulness, the very existence of the Society is a constant check on the ill-treatment of natives, and all who are interested in the future of the Backward Races ought to give this great Society their hearty and practical support.

We must face the fact that there is still an element in our midst which is not in sympathy with native aspirations, and even though in only a few cases does this lack of sympathy show itself in a brutal form, it has to be reckoned with as a distinct danger to the successful solution of the great problem of native advancement and welfare.

THE HON. J. H. P. MURRAY ON COLOUR PREJUDICE.

The Hon. J. H. P. Murray, in a paper which he read before the Royal Anthropological Society on May 15th of last year, when he paid a brief visit to England, made some very significant remarks in this connexion. He said :—

"The average white man is often so masterful, and may I add, occasionally so utterly devoid of any idea of courtesy, that he will ride rough-shod over the feelings of the native—for, he will unconsciously argue, a black man has no right to have any feelings at all. I think that this is the attitude that we are all inclined to take up instinctively when we are first brought into contact with the coloured races, and I think further that a strong effort of will and reasoning power is necessary if we are to overcome it. Even as late as 1900 a book was published in America to prove that the Negro was not a man but a beast, created for the service of the white man. Such a crude philosophy shocks us to-day when expressed in this bald unqualified manner; for, though we may not always be quite sincere when we talk of the duty of protecting the 'inferior races,' and when we say that their interests are 'a sacred trust,' still we have at any rate, the grace to assume a virtue even if we do not possess it, and at least to pretend that in all administrative action the interests of the natives must come first. Not that I would suggest for a moment that it is all a pretence. The theory of the priority of native interests has been called a 'truism' by Sir Frederick Lugard, and doubtless for many years it was so regarded by English writers on the subject, and probably the theory has even been carried into practice by the majority of Crown Colony Governors. But I cannot help thinking that during the last few years there has been a reaction against this view of administration, and that there is a growing tendency to regard the native and his lands as the spoils of the conquering and superior race, to be exploited by the members of that race primarily for their own benefit. I do not mean that you will find writers who have the courage to put their views in this plain and unvarnished language, for, so far as I know, all still pay lip service to the 'truism' of Sir Frederick Lugard; but in actual administration, I fancy that the importance of native interests looms less large at the present time than it did before the War."

"Few, if, any nowadays, in English-speaking countries at any rate, would go so far as to deny the existence of this responsibility towards the natives, but many would in fact, though not perhaps in word, subordinate it to other objects. For instance, if some scheme for the development of a territory promised favourable results from a financial point of view, but was likely to prejudice the best interests of the native inhabitants, I think that you would find that a majority of people would be in favour of going on with the scheme; though they would pay the theory of responsibility the compliment of trying to make out that the natives would not suffer so much after all. In the jargon of the present-day psychology the old idea of treating races not as human beings but as a means to an end, still exists in the unconscious and not infrequently succeeds in emerging therefrom and in expressing itself in action."

These are serious statements by one who is thoroughly competent to speak on these matters. As I have already said, it is no use living in a "fool's paradise." We must recognise the fact that there are numbers of people who still tenaciously cling to the idea that the world was made for the dominance of the white race, and they are not prepared to give any adequate recognition to the rights of the coloured races in any broad and generous spirit. Those who hold these views are not all brutal and selfish people by any means. If they were, it would be an easy matter to deal with them, but there are many amongst them, who are perfectly respectable and conscientious people who honestly believe that the policy which makes the Backward Races the servants of the white man, is not prejudicial to their true interests, just as at one time many good people defended slavery in the same way and on the same grounds. These are the people whom it is urgently necessary to convince. The weight of evidence is against them and it is of vital importance that the widest publicity should be given to this evidence. The progress of the British Empire and the progress of the world does not and cannot mean the advantage and progress of a favoured few. The mere fact that the coloured races number two-thirds of the human race is enough in itself to discredit colour prejudice and colour distinctions as a bar to the onward march of humanity. Is it rational to suppose that merely because races inhabiting the tropics develop a dark pigment in their skins, they are on this account intellectually and morally incapable of rising in the scale of civilisation, and that they should for this reason be permanently disqualified from cultivating their lands and developing the wealth of those lands for their own benefit? Such a notion will not bear the light of intelligent consideration for a single moment. An Empire that attempts to arrest the progress and development of these many millions of her people and make of them "hewers of wood and drawers of water" for all time, is doomed to fall to pieces sooner or later. This is a question of life and death for us as well as for the coloured races, and it will be well if we see this before it is too late. How long will the coloured races of the world submit to such injustice? The opportunity for development is not the exclusive right of the white man. If we believe in the great destiny of he human race we must believe in the coloured man, because he constitutes by far the greater part of it, and he certainly will not be content to remain in a position of permanent subjection, nor ought we to wish it. There are already mutterings of discontent and stirrings of new life in this dark mass of humanity, which are the early symptoms of coming trouble if our statesmen do not learn in time to meet these demands for freedom and opportunity for development which have been too long denied to them.

DR. DU BOIS ON WHAT THE DARK WORLD IS THINKING.

Dr. Du Bois, the leader of the Pan-African Movement, says in his book "Dark Waters":

"What then is this dark world thinking? It is thinking that wild and awful as the Great War was, it is nothing to compare with the fight for freedom which black and brown and yellow men must and will make unless their oppression and humiliation and insult at the hands of the white world cease. The dark world is going to submit to its present treatment just as long as it must and not one moment longer."

It is only fair to Dr. Du Bois to say that he himself does not recommend any resort to violent measures. I had the privilege of being present at several meetings presided over by him when the Pan-African Conference was held in London last year, and I was much impressed by the wisdom and moderation of the speeches which were made, but Dr. Du Bois very wisely warns us what "this dark world is thinking," and it is well that we should take note of what he says. They have not the control of arms or ammunition at present, but France is training a huge army of black troops which, if a collision between the black and the white races does occur, may seriously increase our difficulties in years to come. The moral of all this is, avoid the possibility of collision by adopting a "right policy."

Mr. Basil Mathews, in that same foreword from which I have already quoted, says :—

"The rise all over the world of vigorous and often revolutionary race movements has made this whole issue of the relation of the white races to the backward peoples. . . . the central problem of world politics for the twentieth century."

The Hon. Sir Arthur Lawley on the Vital Importance of this Problem.

The Hon. Sir Arthur Lawley, presiding at a meeting of the Royal Colonial Institute early this year when the subject under discussion was "The Problem of the African Native," said :—

"Transcending every other problem in Africa to-day is the question how far European civilisation is going to affect the natives, many of whom are intelligent and capable. They claim the right to share in the privileges of civilisation, and the question is, what are we to do with these people ? They cannot be ignored ; they are contributing year by year more and more to the national wealth, showing their capacity and their aspiration to rise in the social scale. They may become an element of great good if properly handled ; or, on the other hand, they may become a potential menace to the whole of Africa. I believe that when the men who guide the destinies of Africa deal with the question —and the sooner the better—it should be done in a spirit of generosity, sympathy, and statesmanship."

A policy which will drive these millions of our fellow creatures to desperation is obviously a peril of the first order to the British Empire, and in order to avoid this peril we must endeavour to find a safe and sufficient outlet for this mass of new life which is rapidly asserting itself and mingling its activities with the great civilised order of the world. This is the day of our opportunity. To-morrow it may be too late.

There is a tide in the affairs of men,
Which, taken at the flood, leads on to fortune ;
Omitted, all the voyage of their life
Is bound in shallows and in miseries.

The Two Most Pressing Demands for Great Britain.

The two most pressing demands for Great Britain at the present moment are raw materials and markets.

With regard to raw materials, the bulk of these come from the tropics and we are entirely dependent upon the coloured races to produce them. The white man never has done and never can do the manual labour of the tropics. It is a matter of vital importance to Great Britain to discover a method of developing the tropics under which we can secure the maximum production. The system under which we can get the most raw material for our factories is the system we want. The crux of this problem is obvously the "willing worker" because only with the "willing worker," can we expect to get the best results.

Mr. J. H. Harris, M.P., on the "Willing Worker."

This point is very clearly brought out by Mr. J. H. Harris, M.P., in an article which appeared in the "Manchester Guardian" of November 27th last year, under the title "Cotton Growing in Uganda. Native Producer versus White Control."

He says that the total value of the cotton in Uganda for the whole of 1923 will probably exceed £2,000,000. Less than fifteen years ago it was only £20,000. This astounding achievement is the result of the natives working as free and independent men, cultivating their small holdings with the help of their wives and families.

The Settlers' organ of the neighbouring Colony of Kenya makes an attack on this policy and asserts that it is "wasteful." They say that from 1,000,000 to 1,500,000 out of a population of 3,000,000 were employed in producing this crop, and that under European supervision, scientifically controlled, £5,000,000 worth of cotton would have been produced with the same amount of labour, instead of merely £2,000,000 worth. This contention is based upon the assumption that the 1,500,000 workers would have been available as wage earners and that they would have worked as cheerfully and effectively under the white man as they would have done for themselves. Taking the average family as five the 1,500,000 workers would include only 300,000 men and it is not conceivable that all of these, or anything approaching that number, would have been willing to leave their homes and work under a white man for wages. The striking and important thing about this amazing outburst of production is the fact that it is the direct result of the encouragement of independent native labour, and if we add to this the not less astonishing achievement in connexion with cocoa growing in Nigeria and the Gold Coast, we have a very strong case in support of this policy. As Mr. Harris points out, "the vital factor is the willing worker," without whom nothing can be accomplished. When once the native is fired with the producing spirit, there is hardly any limit to his power to produce. No system which fails to evolve the willing worker can, in the final issue, be regarded as economically sound, because it cannot give all-round satisfactory results, and sooner or later it is bound to break down altogether.

THE TWO COMPETING SYSTEMS COMPARED.

Let us examine the two great competing systems for the development of the tropics in the light of this test.

1. Development by means of big plantations owned by the white man.

2. Development by means of native peasant proprietors, working on small holdings, with the help of their wives and children.

Taking the big plantation system at its best, because it is only right to recognise that while this system undoubtedly lends itself to great abuses, which is one argument against it, it would not be fair to condemn it on the ground of these abuses alone; and, looking at it apart altogether from the questions of tyranny and brutal outrage, which so often are found in connexion with it, there are three serious objections which are inherent to it even in its best forms.

Under this system: 1. The natives, speaking generally, are deprived of their land, and a people who sell their land sell their independence, often literally, for a mere "mess of pottage." 2. The home life of the people is broken up because the men are taken away from their wives and families to great distances, and often for long periods. No system which breaks up the home life of a people can be a good one. 3. They are herded together in great compounds under unnatural conditions, which often lead to abnormal forms of vice, especially when they remain for long periods.

Contrast with this the opposite system, where the native cultivates his own land for his own benefit with the help of his wife and family. Under this system he is 1. A free man. 2. The home and village life is strengthened because every member of the family is a helper in the work. 3. The man is living a natural and healthy life surrounded by his wife and family.

Which of these systems is most likely to produce the "willing worker," and which system is likely to result in a happy, contented and progressive people? There can be no doubt about the answer, and the facts on the Gold Coast, in Nigeria and Uganda, and other places, are overwhelmingly in favour of development on independent lines.

Governor Murray, in the paper from which I have already quoted, says: "It is obvious that the native must work, but the question is, how are you going to induce him to work? You can force him to work for the benefit of a white employer, either directly (to which great objection would be raised) or indirectly, by means of a tax (which is permissible), or you can compel him to work for his own benefit, as we are doing in Papua. The latter is, in my opinion, the only really effective way of dealing with the question. To compel a native to work in the interests of a white man certainly has an unpleasant appearance, and has been distinctly disapproved by the League of Nations, and, furthermore, it leads to nothing. He has learned to chop, scrub, and pick weeds, but it is quite possible that he may have learned little else. And if we are going to keep him till the end of time as an unskilled labourer working for the white man at a wage of 2s. 6d. a week, I do not think he will have much to thank us for. Instead of keeping the native indefinitely as a servant of the white man we must induce him to strike out for himself, with plantations and other industries of his own."

THE IMPORTANCE OF NATIVE AGRICULTURE.

Later on in the same paper Governor Murray says:—

"Native agriculture is important as tending to conserve and stabilise the native race and to prevent the native from losing his individuality and from sinking down into the position of a tenth-rate white man, aping the lower and more contemptible aspects of the white man's culture, but unable to recognise or appreciate the higher. Native agriculture in Africa has been recommended by high authorities as superior to any other in rapidity of expansion and general efficiency. 'I have but little hope that I shall ever be able to say the same thing of Papua, though my successors may; but even if Papuan agriculture is never to be efficient I should still regard its encouragement as all important on moral grounds, as saving the race from disintegration."

Sir Frederick Lugard on Character Results of Independent Labour.

The effect of the system of independent labour on character development is an important consideration. Sir Frederick Lugard, who is perhaps the greatest living authority on native questions, published in 1922 a very important work, entitled "The Dual Mandate in British Tropical Africa," which is a perfect compendium of information on this great problem.

On page 294 of that work he says:—"Cecil Rhodes was an ardent believer in the efficacy of individual small holdings as an aid to self-respect." And he himself says on the same page:—"I believe that there is nothing which can so effectively tend to eradicate the servile habit of mind in a people who have for generations been accustomed to regard themselves as slaves or serfs, as the sense of responsibility of the free occupier of the land." On page 295 he says:—"The labourer who works on land which is not his own, whether as the serf, or even as the paid servant of an estate owner, has little interest in its improvement during, and none beyond, his own lifetime. Individual proprietorship is no doubt inimical to the supply of wage labour for large estates, but it makes for individual progress, thrift, and character. It is the strongest inducement to good farming, and politically an asset to the Government." He adds that the French verdict is the same. They report after careful enquiry:— "The system of individual ownership is incontestably the one which is most favourable to production."

These are weighty opinions which cannot safely be disregarded. In addition to the fact that a system of independent labour develops initiative, calls out energy and awakens ambition, all of which are tremendous factors in the worker, calculated to secure the maximum of production, there is another great fact which we cannot afford to ignore. Primitive peoples, and especially the African, who far out-numbers all the other primitive races in the world, do not take kindly to working for a master for wages. Such a man loves his own little patch of ground around or near his own home and would rather be poor, under such congenial conditions, than rich, working for wages away from home. If, in shaping a policy for his future development, we do not take this into account, we are doomed to failure from the start.

The advocates of the big plantation policy say: "We will give him a little plot of land near our plantation and let him bring his family and make his home with us"; but this does not meet the case. What will happen if the plantation company collapses, and a considerable percentage do collapse. The bottom immediately falls out of the native world and they are immediately plunged into a state of helpless misery and distress. It is not a sufficiently broad and stable foundation upon which to build a future of progress and prosperity.

In this connexion Governor Murray says, speaking of the future of the Papuan native under Australian rule:— "There are many dangers in his path, and the greatest danger of all may come from what I may call a benevolent capitalism—a capitalism which will use the native solely as a means towards the development of the country in the interests of non-resident capitalists, to the disregard of the future of the native race as a whole and its eventual advancement to a higher grade of civilisation. Such a capitalism disguises itself by an excessive and scrupulous care for the health of the native, for their education, especially their technical training, and even occasionally by zeal for the proper feeding and accommodation of the indentured labourer, and it is possible that, in this guise, it may so far impose upon the Australian public and the Commonwealth Government as to persuade them to allow it to control the administration of Papua, and if so, the doom of the Papuan is sealed—*he will remain a servant till the end of time.* If, however, he escapes this fate, he may have a fairly prosperous future before him, and I for one shall be much surprised if eventually he does not show himself a better man than his cousin the Malay."

NO ONE SYSTEM ALTOGETHER GOOD, BUT INDEPENDENT LABOUR PROMISES BEST RESULTS.

I am not an extremist. Truth is seldom if ever found in extremes. I do not wish to suggest that development in the tropics by means of plantations owned by white men is altogether bad, or that development by natives working on independent lines is always and altogether good. Each system has its drawbacks and its advantages, and perhaps the best results will be achieved by a happy combination of the two with a very large preference for the independent native proprietor. Sir Frederick Lugard, in the book from which I have already quoted, says: "Plantations of limited area owned by Europeans are useful as object lessons to natives to improve their methods." Governor Murray, notwithstanding his strong predilection for the native peasant proprietor, is also of this opinion. It is all a question of degree. If the big plantations dominate the country and stand in the way of all independent native development they become an undoubted evil, but, as Sir Frederick Lugard says, if they are of "limited area" they may prove beneficial in many ways. For the young unmarried men they are a means of discipline and training in industry which is all to the good, but it is not good for the plantations to be too large, or for the period of indenture to be too long. What is wanted is the individual white planter of the right sort, rather than the huge company with capital running into millions, because the financial necessities of such big concerns compel them to do everything on a large scale and the individuality of the native is threatened by the vastness of the operations. He learns less, because he does one thing continuously instead of having a variety of work, as would be the case on a smaller plantation. Moreover, these enormous companies make too big a demand both for land and labour to be good for native developments in the country.

From the economic point of view the most serious objection to development by means of big companies as against the native peasant proprietor is that in their case all the net profits are sent to non-resident shareholders, and this constitutes a steady drain upon the wealth of the country which permanently impoverishes it.

On the other hand, under the system of development by means of native peasant proprietors, the profits on the produce remain in the country in the hands of the natives, and having the means to purchase, and the constantly increasing desire to possess the goods which England supplies, markets are opened up for us under this system which would be practically or comparatively non-existent under the opposite system. This is an extremely important point and should be given due weight.

If, then, as we have seen, by means of the native producer: (1) The maximum of raw material can be obtained, and (2) Markets can be opened up for British manufactured articles which otherwise would not be secured, it is clear that this policy is one which should be encouraged to the utmost in the interest of Great Britain.

So far as the future of the natives is concerned, it is equally clear that this policy is in their interest, indeed it may be said to be the only policy which offers them any prospect worth calling a future at all.

HOW THIS POLICY CAN BE BEST PROMOTED.

It only remains for us to consider now how best this policy can be promoted and applied to the Backward Races in the various parts of the British Empire in order to secure for them the full benefit of it, and this brings me to the suggestion that here we have a great new field of opportunity for the missionary enthusiasm of the churches. The native producer needs guiding, and in many cases he requires financial assistance in order to get him started on this new path of industry. Upon whom does the responsibility rest of giving him the help he needs at this critical stage? Many will at once reply, "Upon the Government," and while I agree with this reply I would add, "and upon the Christian Church."

Both have a common and admitted responsibility for the future of the Backward Races, and both should mutually co-operate in the endeavour to organise the industry of the natives on sound progressive lines for their own benefit.

A NEW FIELD OF SERVICE FOR MISSIONARY ENTERPRISE, CO-OPERATING WITH GOVERNMENTS.

This is a great opportunity for the laymen of the churches, as it calls for their special knowledge and experience and for their powers of commercial organisation and control. This would necessitate the creation of a new type of missionary society, as the existing societies are not suitably constituted to undertake commercial responsibilities on a large scale, nor would it be advisable for them to attempt it, for many reasons. The funds for this purpose should be raised by means of loans or shares at a fixed low rate of interest, say 5 per cent., and all the profits after the payment of this interest should go to the natives who produce them, to finance their social, intellectual and spiritual progress and improvement. The work should be done on sound business lines, as nothing would be gained by pauperising and coddling the natives. Every effort should be made to work in close co-operation with the Government. The members of the staff should be paid on the same basis as medical and other missionaries, because only in this way would the right type of man be secured. This work would call for genuine sympathy and a deep and sincere interest in the welfare of the natives. The great service which the churches could render would be by finding such men and sending them out. The churches have sent out Evangelical missionaries, educational missionaries, women missionaries, and medical missionaries, each of whom are doing their special work very effectively, but we have yet to see, on any appreciable scale, the business missionaries, who, on the same terms and in the same spirit as these other types, will devote themselves to this great task of helping the Backward Races to learn the duty of work as well as of worship, and to protect them from unscrupulous exploitation. Such organisations as I have outlined, entirely managed and controlled by Christian business men, would immensely strengthen every existing form of missionary work without in any way interfering with the work of founding or controlling native churches, as this can very well be left to the clerical missionary. They should also prove to be very helpful agencies in assisting the various Governments concerned.

The Papuan Industries, Ltd. A New Organisation of this Type.

The Papuan Industries, Ltd., with which I am connected, is a missionary organisation of this kind. It has now been at work in the Torres Straits and in British Papua for a little over seventeen years with results which are a striking proof of what can be done on these new lines. It is only a small enterprise, working on quite an insignificant scale, but just as in the laboratory, experiments with small quantities can conclusively demonstrate possibilities on an unlimited scale, so I claim that we have proved conclusively the value and possibility of this new type of organisation, though, owing to losses due to the War, we have not yet attained commercial success.

With your permission I will conclude my paper by giving a brief account of the origin of this enterprise and what it has already achieved.

Some years before the Papuan Industries, Ltd., was started, when I was a missionary of the London Missionary Society, I came across some natives on one of the islands of the Torres Straits in a pitiable state of starvation and misery. Instead of applying to the Government for relief, which was the usual thing to do under such circumstances, I offered to buy a boat for them out of my own money, and give them a chance to work, and thus enable them to provide for themselves and their wives and families, instead of always depending upon the Government for doles of food. They very eagerly accepted my offer, and worked with such energy that within eighteen months they not only provided for their own requirements, but they paid off the whole cost of the boat.

The late Hon. John Douglas, C.M.G., a former Premier of Queensland, who held the office of Government Resident for the North at the time, was so pleased with this experiment in self-support, that he arranged for the whole of the business transactions in connexion with the working of this boat to be dealt with through his office. When it proved to be such a great success, he started other boats, and when the Papuan Industries, Ltd., arrived on the scene some years later, conditions were ripe for further developments. Owing to our opportune arrival, the work soon went ahead and a rapid increase in the number of boats quickly took place, the Government and the Papuan Industries, Ltd., finding the necessary capital in equal proportions. At the present time there is a fleet of twenty-six native owned boats at work, of an average value of £400 per boat, making a total value of over £10,000 for the fleet, *all of which is owned and has been paid for by the natives out of their own earnings.*

The total value of the produce collected by these boats in one year, viz., in 1921, as certified by the Government's Auditor, amounted to over £16,000.

Until quite recently all the Eastern Island boats went to Thursday Island to the Government, and all the Western Island boats came to us at Badu. In July, 1922, the Government, after careful investigation, decided that it would be advantageous to the natives to do their business away from the temptations incidental to a seaport town, and they, therefore, asked us to take over the whole of the work which they were doing at Thursday Island.

Everything is done on a strictly business basis, because we believe that it is demoralising to give anything for nothing in work of this kind, more particularly in the case of natives, who, like children, soon begin to expect it as a matter of course.

We charge 2½ per cent. commission on all the produce we handle, reasonable retail prices for all the goods we sell, and freight on all the cargo we carry to and from Thursday Island.

All the marine produce is sold in Thursday Island by public tender under the supervision of the Protector of Aboriginals.

Five per cent. of the gross proceeds is handed to the Government, and is banked by them to the credit of the various islands concerned, under the name of Island Fund. This is held as a reserve for the "hungry times," which still periodically occur, and also for any other special need which may arise.

After sundry deductions for gear and food supplies for the boats, and something for the extinction of the debts on the boats, if such exist, the natives receive the balance in cash which is distributed amongst them in proportion to their catch. *Thus each man is rewarded according to the work he has done.*

The Government Auditor regularly audits our books, and all the various arrangements are carried out under the direction and supervision of the local Protector of Aboriginals.

The natives are working with surprising energy under these new conditions. Their villages are steadily improving, they regularly and generously contribute to the support of their churches, and the general improvement in character and physique is most noticeable.

These facts sufficiently prove how keen the natives are to work, when the right inducements are offered, and how capable they are of making good use of their opportunities, if the necessary financial assistance is given to them.

The moral of this and of all I have said is,

1. Believe in the native.
2. Give him a chance to become an independent and self-respecting worker.
3. Let Governments and Christian Missions co-operate in the work of assisting and guiding him on the path of industry.

If we do this our reward will be,

1. An abundant supply of raw material from the tropics for our factories.
2. The opening up of new markets for our goods on an almost limitless scale.
3. We shall have a happy and prosperous people in these distant Possessions who will be a strength to our Empire and a credit to our statesmanship.

But it is even a greater question than this. I have called my paper "The Commercial Future of the Backward Races," but the fate and future of two thirds of humanity involves the fate and future of the whole human race. God has "made of one blood all nations of men to dwell upon the face of the earth." It is His will and our vital interest that we should "dwell together in unity." For good or for ill we are all one body. "The eye cannot say to the hand, I have no need of you, and the head cannot say to the foot, I have no need of you." If the War has taught us one lesson more clearly than another it is the great truth that the whole world is interdependent and the welfare and happiness of every nation is bound up with the welfare and happiness of all the others.

In addition to religion and government, all the sciences, Economics, Sociology, Agriculture, etc., have their part to play in the solution of this great problem, for it involves the destiny of all mankind. Hate, contempt, racial animosities threaten to disintegrate and destroy all the accumulated gains of civilisation, if we are not careful to guard ourselves against them. Idealism has recently been treated with scorn and denounced in high quarters, as a danger but surely the lack of idealism is the greater danger.

If we approach this great and pressing problem of the future of the Backward Races in the spirit of justice, sympathy and love, we shall not fail to arrive at a solution which will benefit us, perhaps even more than those whose good we seek.

DISCUSSION.

Major Sir Humphrey Leggett, D.S.O., R.E., who relieved Sir G. Le Hunte in the chair on the latter leaving the meeting to catch a train, said Mr. Walker had harped all through his paper upon the need for what he termed the "willing worker." We were not without experience in the older countries of the world as to the distinction between those who worked with a will and those who did not. Lord Askwith, who was present, knew more perhaps than any man in England of the psychology which went to make up the willing worker. Dealing with the problem as it affected the backward races of the world, he thought Mr. Walker had perhaps been just a little unappreciative of what had been done, what was being done, and what it was the definite intention to do in the future in regard to the enlistment of the native willing worker in the development of his own country and for his own advantage. It was true that in certain backward countries there had been matters which he would not call scandals, but rather experiments which had not been always satisfactory, but what stood out above all in the British administration of certainly the most backward Continent of the world — Africa — was the great success rather than the failure which had attended the enlistment of the willing worker in the service of the world and for himself. Nigeria, the Gold Coast, Uganda and Tanganyika had within the past twenty years been added to the list of, should he call them even, progressive countries, rather than the backward countries of the world. It was the British race which had discovered, or, at any rate, had adopted with enthusiasm, the principle of trusteeship for the backward races. Other European nations which had found themselves called upon by accident or design to take part in the administrative problems of the backward races had not always regarded their responsibility in the same way; but thanks to the great lessons handed down by the missionaries from the days of Livingstone, and thanks to the lead taken in this country a hundred years ago by those who brought about the abolition of slavery, it had never been lacking in our own race to endeavour to give the utmost freedom to everyone who was backward morally or economically, be he black or white. We had lived in this last generation to see that principle of trusteeship for the native races adopted by other European countries, and to see the territories of backward races being administered and developed by way of the willing worker; but the author was right when he said that those matters should be emphasised. They were known and practised, but the more widely known and practised they were the more successful would they be. Mention had been made of the enrolment of a quarter of a million African troops by our ally, France. What he was about to say, of course, was but an individual view, but he could not help thinking, when one realised all the possibilities that might follow from enrolling large masses of the backward races in the military employ of a European power, from furnishing them with arms, and from the teaching of violence which followed, that that was not a forward, but a backward step. If there was to be a new understanding between our country and our ally, France, he trusted sincerely that the Prime Minister and the Cabinet would not overlook the chance of saying a word as to the great responsibility which rested upon the white Powers who administered Africa, and what a fatal thing it was to enrol black men to serve in the armies of white Powers. He regretted that Sir Frederick Lugard was not able to be present; but he had written to the Secretary of the Dominions and Colonies Section as follows: —"I should much have liked to accept your kind invitation to say a few words and to congratulate the lecturer on the success of his excellent scheme of self-help for native races. Dr. Rivers's remarks in his enquiry as to the cause of the decrease in population in Melanesia are very pertinent. He, like Professor Elliott-Smith and others, rightly places the lack of interest in life as the foremost cause of a decreasing native population. Good government is no substitute for this. The recent admirable report from New Guinea, which comes within my work as British Member of the Mandates Commission, gives emphasis to this, I am glad to note."

Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, said, in speaking of New Guinea, Mr. Walker began the history of that country with the Governorship of Sir William MacGregor, and also spoke of the resolutions with regard to firearms and drink as having been first started during the Governorship of that gentleman. That was not quite correct. It was in 1885, before either Sir George Le Hunte or Mr. Walker went to New Guinea, that he (Lord Askwith) was in Papua as an honorary member of the staff of Major-General Sir Peter Scratchley, High Commissioner of the Western Pacific and Governor of a proposed Protectorate of New Guinea, and it was then that those ordinances had been either promulgated or confirmed. He knew that definitely because he had personally assisted in drafting them. He mentioned Sir Peter Scratchley's name because he did not like his old chief to be forgotten. It was unfortunate that Sir Peter died in New Guinea of malarial fever, his body being brought back to be buried in another clime. With regard to the paper, he hoped Mr. Walker would not think he was criticising too much when he said that, although he entirely endorsed the idea of sympathy between white and coloured races to which the lecturer alluded, and accepted his view that he was not an Extremist, yet he could have wished that some of the phrases in the paper might have been somewhat toned down. He could not but feel that there was a rather unreasonable indictment, in certain of those phrases, of the work which the British Empire had been doing for many generations past and was at present endeavouring to do. Mr. Walker used the following phrase, for instance—he supposed it alluded to the British Empire—"An Empire that attempts to arrest the progress and development of these many millions of her people, and make of them 'hewers of wood and drawers of water' for all time, is doomed to fall to pieces sooner or later. This is a question of life and death for us as well as for the coloured races, and it will be well if we see this before it is too late. How long will the coloured races of the world submit to such injustice?" and further on Mr. Walker remarks: "There are already mutterings of discontent and stirrings of new life in this dark mass of humanity, which are the early symptoms of coming trouble if *our statesmen* do not learn in time to meet these demands for freedom and opportunity for development which have been too long denied to them." In another place he says "without sympathy and understanding it is impossible for men, white or black, to pull together. If these elements are not cultivated, *war*, with all its waste and misery, *is inevitable*" Then Mr. Walker cited a quotation from a certain doctor's book, in which the strange statement was made:—'What then is the dark world thinking? It is thinking that wild and awful as the Great War was, it is nothing to compare with the fight for freedom which black and brown and yellow men must and will make unless their oppression and humiliation and insult at the hands of the white world cease. The dark world is going to submit to its present treatment just as long as it must and not one moment longer." The lecturer had suggested that violence was not recommended by the doctor himself in that book, but one had a certain feeling of doubt as to where that dire threat was coming from, and whether it was true. Was it from Japan, a nation allied to us in the Great War, whose recent sorrow the Society was going to hear about the following evening from a distinguished member of the Japanese Embassy? Was it from China, where one would think that, if anything, humiliation and insult were being endured by some of the white races rather than the other way? Was it from Siam, a flourishing independent kingdom? Was it from India or the Philippines, where two great nations were endeavouring to find measures of self-government which they could give to the peoples of those countries? Was it from Sarawak, Borneo, Malaya or Burma, countries which we had been accustomed to think we had been successful in governing? Was it from Iraq or Arabia, which we thought we had assisted by overthrowing the dominance of the Turk? Was it from Egypt, to which we had lately given independence? Was it from Uganda or the Sudan or the Gold Coast or any of our colonies on the West Coast? Or, turning to other nations, had there been any signs of revolution in Morocco or in Senegal, or had the black races in the United States of America been proposing to overthrow the Government of that country? He could not help thinking that that statement was a very gross exaggeration. The lecturer had given some very interesting accounts of plantation life in New Guinea. It was important that care should be taken that settlements like Port Moresby should not become centres where half-castes or poor blacks and others should settle round the European Settlement, but that as much independence, assistance and direction as possible should be given to the various valleys and sea coast towns which abounded in that country. When he first visited Port Moresby there was only one house there. Now it was quite a big town. New Guinea, however, would take a very long time to develop. It had deep gorges, razorback hills with high mountains beyond, and its jungles, rivers and swamps were physical features which made commerce on a wide scale very difficult. Further, the white man was not enamoured very much of the insects which abounded there. On the whole, he did not think New Guinea would be of very great commercial importance unless a good deal of gold was discovered there; but the method which was being pursued there was one which seemed to him to be very suitable for the kind of country it was. His criticism upon the paper was that it was very dangerous to generalise in such a wide manner as Mr. Walker had done about the white men and coloured races, and about countries which the lecturer had not himself visited. It was best to look at the problems affecting each of those different countries and to solve them with the will and endeavour to do it, with sympathy and for the advantage and assistance of both races—white or coloured.

MR. CHARLES H. ROBERTS said as he was connected with the Anti-Slavery and Aborigines Protection Society, to which Mr. Walker had given a most handsome testimonial, he might be allowed to thank the lecturer for the way he had spoken about the work of that Society. Mr. Walker had been good enough to say that its work was of value, partly in calling public attention to unfortunate abuses discovered in different parts of the world. Lord Askwith had not put it too highly when he said that the ideals of the British Empire were higher than those of any other previous Empire in its treatment of the backward races, yet he (the speaker) was afraid that we did not always act up to our ideals, and unfortunate incidents had occurred where individuals had not absorbed or acted upon those ideals. Lord Askwith had combated the lecturer's thesis that if the treatment of the backward races was not inspired by the highest ideals of justice, there was a possibility of trouble in future. The kind of trouble which was in Mr. Walker's mind was not that of a forcible attack upon the white position, but that, unless our practice was on a level with our highest ideals, we might find in different parts of the world—Africa, for instance—unrest and racial trouble which would certainly upset equanimity and cause trouble. Even in unexpected places there were to be found signs of revolt against the dominance of the white race. He had read books which had made him feel that that possibility was not altogether to be ignored. It was quite true that our principle of trusteeship had led to a high level of treatment of the backward races, but he thought that might be qualified by the following consideration: He was not quite certain whether it could be said that in all British-speaking communities there was an absence of colour prejudice. He was not quite sure whether we had not more of a colour prejudice (though we repudiated it in our legislation) than, for instance, the French. It would have been interesting if Mr. Walker had given a few more details of the industrial work to which he had referred. He noticed the rather ominous statement that the particular industrial society referred to had been 17 years in existence, had done admirable work, but had not yet proved a commercial success. Unfortunately, the combination of philanthropy with business was so extraordinarily difficult that, with the very best motives in the world, and with the highest ideals, it seldom succeeded.

Colonel Sir Charles E. Yate, Bt., C.S.I., C.M.G., M.P., said he had been pleased to hear Lord Askwith criticise the manner in which Mr. Walker had failed to appreciate the trusteeship of the British race in connexion with backward races. Although Mr. Walker, he believed, was an Englishman, the bulk of his paper seemed to him personally to be nothing else than a violent attack on his own fellow countrymen. He used the following words: "These are serious statements by one who is fully competent to speak on these matters," but he (the speaker) could not help having a doubt as to whether the lecturer, whose experience apparently was gained in Papua, was competent to speak for the whole Empire.

Mr. Walker pointed out that that was a quotation from Governor Murray.

Sir Charles Yate, after expressing regret for the mistake, said he still thought Mr. Walker had looked at the whole matter from a very narrow point of view indeed, and he agreed entirely with Lord Askwith that many of the statements in the paper were gross exaggerations. He felt compelled to disagree with Sir Humphrey Leggett's disapproval of the enlistment of native soldiers. One had only to take India, Egypt and the Sudan to see what splendid men the natives had been made by being enlisted as soldiers; they loved their British officers, and they followed them to death if necessary; and enlistment, he thought, raised them in the scale of humanity, not lowered them. He, therefore, could not agree with Sir Humphrey Leggett in thinking that it was a bad thing for the native to be enlisted as a soldier in the British Army.

Mr. Travers Buxton remarked that in his latest report the Governor of Papua had contrasted the plantation system with the system of native cultivation, very much to the advantage of the latter, if it could be worked. In Papua, which was very backward, it was not possible to get the natives to work as free labourers; indentured labour was necessary. The capitalistic system could not be carried out very extensively, and, therefore, Mr. Murray held that a combination of the two was the right thing for the development of Papua—the capitalistic system, as Mr. Murray called it, and the native working on his own account. Mr. Murray was in this country a few months ago, and had given a most fascinating account of the people of Papua and what he had done amongst them. Those who knew Mr. Murray's reports, and who had followed the work which had been going on in that country, knew what a testimony it was to the sympathetic, wise and consistent administration which had been carried out for so many years by one Governor after another. Reference had been made by Sir Frederick Lugard to the need of supplying the native with an object in life. In some essays on the Melanesian native, published a few years ago, Dr. Rivers pointed out that the native who had been accustomed to head-hunting and tribal wars, when he came to be civilised to some degree, and when the white man came along and insisted on his obeying certain laws and observing order, he found a lack of interest in life—boredom. Therefore, from the lowest point of view, as well as for the reasons on which the lecturer had laid stress, it was very important to get the native to become a willing worker in order to save him from being exterminated, because the result of his intense boredom and lack of interest in life was that he died, and thus became of no use to himself or anyone else.

Mr. E. Kilburn Scott said he was certain Mr. Walker had had no intention whatever of making any attack on those gentlemen who had so wonderfully administered the outposts of the Empire in the past. The type of men Mr. Walker attacked were the beach-combers and some of the traders.

Sir Charles Yate drew Mr. Kilburn Scott's attention to the statement on page 5 of the paper regarding the trouble which it was threatened would ensue in this dark mass of humanity: "If our statesmen do not learn in time to meet these demands for freedom and opportunity for development which have been too long denied to them." He thought it would be agreed that that referred to the men who administered the Empire.

Sir Thomas J. Bennett, C.I.E., said that after the discussion which had taken place, he thought the vote of thanks which he was about to propose was less a vote of thanks than a mitigation of censure! Although there was a great deal in the lecture to which he personally objected, the worst parts were not Mr. Walker's; as a matter of fact, the latter were the best. The quotations were the worst parts. He thought the person who had led Mr. Walker astray had been Mr. Murray. He (Sir Thomas) did object to Mr. Murray saying that the average white man was so masterful and occasionally so utterly devoid of any idea of courtesy that he would ride roughshod over the feelings of the native. Sir Charles Yate had had many years' intercourse with the natives of India, and had not been masterful, devoid of any idea of courtesy, or ridden roughshod over the natives. When that was presented to the world as the sort of attitude of the average white man to the native, personally he rather objected to it, and he would suggest to Mr. Walker that his paper would have been a much more admirable one if he had left Mr. Murray out of it. There was one omission to which he desired to draw attention. Mr. Murray spoke of the idea of the priority of native interests being recognised as a truism to which lip-service was paid, and said that our policy was not really determined by that principle. He was quite sure that that statement had been made before the White Paper on Kenya was issued. Everyone knew that priority of native interests had been affirmed as a principle of high State policy in that White Paper. That was a determining point in the policy of this Empire towards the backward races, and it should be recognised by the audience that afternoon.

PROFESSOR H. E. ARMSTRONG, F.R.S., said he seconded the vote of thanks most heartily, for the reason that he thought it had to be recognised that men such as Mr. Walker were a class of individuals who in the past had done this Empire an enormous service, and he was sure the audience were glad to have an opportunity such as the present of thanking one of them.

The motion was carried unanimously.

MR. WALKER, in reply, said he thought he must plead guilty to not having expressed himself sufficiently as to his appreciation of the work of the Administrators of the British Empire. He did recognise that our Empire had the best record of any Empire in the world. He had perhaps dwelt too much on the dark side of the subject. He did not think it was quite true to say that there was not one word of appreciation in the paper of the work which the Empire had done, because he had referred, in connexion with Papua, to the three magnificent men who had been there. He was sorry he had omitted to mention the name of Sir Peter Scratchley, who was a martyr and died in the course of his work. He was a great pioneer Commissioner in New Guinea, and belonged to the very best type of Empire Builders. At such a late hour he would not attempt to deal with the various other points which had been raised in the discussion. He thought the paper was not as worthy as it should have been of such an occasion. He was indeed very conscious of its deficiencies, but he hoped the audience would forgive him. Perhaps he had done Governor Murray an injustice in the quotations he had put in the paper.

The meeting then terminated.

"BAYER 205." A SLEEPING SICKNESS REMEDY.

The Berlin Correspondent of the *Manchester Guardian* contributes an interesting account of an address recently delivered by Dr. Kleine on his experiences and experiments in Rhodesia and the Belgian Congo.

"Bayer 205" is a synthetic drug. Its composition is being kept a secret. It was discovered three years ago. In 1921 the Bayerische Aniline Dye Works asked Dr. Kleine to test its efficacy in tropical Africa, for the tests that had been made in Germany seemed to promise success.

Sleeping sickness is caused by two varieties of flagellate bacilli called trypanosomes and discovered by Sir David Bruce. They are transmitted by two varieties of the tsetse fly, *Glossina morsicans* and *G. palpalis*. Transmission is not merely mechanical. The bacillus has to go through a development that may last several weeks after it has been taken up into the body of the fly before the fly itself becomes infectious.

The disease has three stages. In the first a blood-infection is accompanied by alternating states of feverishness and apparently normal health. In the second stage there is a swelling of the glands. Dr. Kleine showed several photographs of patients whose necks had conspicuous swellings on either side. In the third stage infection of the nervous system, of the spinal fluid, and of the brain-matter sets in. The patients grow violent, and often develop homicidal mania. Eventually they become lethargic and fall into a kind of impenetrable stupor—hence the name sleeping sickness. Dr. Kleine's photographs showed sufferers who were brought to his laboratory on stretchers. Their bodies were terribly emaciated, and their faces had a vacant, stupid look. One photograph showed a homicidal maniac who had been rendered harmless by the Central African equivalent of a strait jacket—a long, heavy tree-trunk with a forked end, into which his neck had been squeezed and fastened.

Dr. Kleine succeeded in curing patients in all the three stages of the disease. In some the deterioration of the nervous system was so far advanced that a restoration to normal health was no longer possible, but the blood of these cases was rendered free of trypanosomes.

PROPHYLACTIC TREATMENT.

This successful sterilisation of the blood is of supreme importance. A patient who has been treated with Bayer 205 ceases to be a source of infection even if he himself does not recover. The complete stamping out of sleeping sickness is therefore only a matter of organisation.

Prophylactic treatment tried on animals was not entirely successful. Experiments were made with cattle, dogs, and monkeys. Dr. Kleine employed a number of negro boys in catching tsetse flies, which were placed with the animals. The number of flies that can carry infection varies with the climate. On an average about one fly in 500 can impart the disease, but as tsetse flies abound in countless myriads, and as each fly can live as much as a year, the danger of infection is very great, indeed whole populations have been decimated by it.

Cattle that had undergone prophylactic treatment did not, after being stung by a parasite-carrying fly, grow emaciated and die, as they would have done without treatment. They showed only slight symptoms of ill-health and remained fit for the market. Monkeys similarly treated developed a slight enlargement of the spleen, but showed no very grave symptoms. There were a few cases of relapse, but these were successfully treated with antimony.

Dr. Kleine's first series of experiments was made at Dombo, a Rhodesian negro village where he and his staff remained for a year. Sick men, women, and animals were brought in, sometimes from a distance of a hundred miles. The patients were not always very tractable. The women particularly wanted to go back to their fields, where they had to stand shrieking and howling to keep the birds away in the mornings and wild animals at nightfall.

The party then crossed into the Belgian Congo at the invitation of the Governor. They were on the march for three weeks. They passed through villages where only women and children were to be seen, all the men being away to catch grubs that are dried over a fire, salted, and kept as food.

At Elizabethville the Belgian authorities gave the party a very friendly welcome. It was here that Dr. Kleine heard that the Ruhr had been invaded. He asked the Governor of the Belgian Congo whether he had not better return to British territory, but the Governor replied that science was science, and that every help would be given to the party of German scientists now as before.

In Rhodesia Dr. Kleine had treated 35 patients. He generally gave three injections, and four or five for particularly grave cases. Subcutaneous injections were found to be rather painful and caused a slight inflammation, so that the comparatively harmless intravenous injections became the rule.

Of the 35, one died from unknown causes. Another, an Englishman, felt so much better that he decided to leave prematurely. He died in London of sleeping sickness. Of the remaining 33 two were dead half a year later (it is not certain from what causes), while the remaining thirty were alive and apparently in good health.

A MALINGERER.

Amongst the 150 patients treated by Dr. Kleine in the Congo were 95 children. He kept them under observation for five months, making frequent blood tests. Only in two cases were trypanosomes found in the blood at the end of the five months. It was impossible to tell whether they were cases of relapse or of renewed infection. A boy who was in the third stage of the disease and had become a raving maniac was quiet after three injections. Another was brought in bound hand and foot, but he, too, was cured. A few very advanced cases were not absolutely curable, although their blood was freed from the infection.

The natives were not long in finding out that Dr. Kleine had a special interest in treating them, and they began to demand payment in the shape of tobacco, eggs, or money for being cured. One native, named Ulimengo, was brought to the laboratory in a state of profound stupor. He seemed to be blind, although an examination of his eyes revealed no defect. He was treated with Bayer 205, and blood tests showed that the injections had taken effect, but there was no change in his conduct. A sample of his spinal-fluid was also taken, but no trypanosomes could be discovered. Ulimengo seemed to be quite harmless, and he was made to sweep the approach to the laboratory during the rare intervals when his stupor relaxed a little. For days he would remain helplessly languid, until one morning he uttered the word "pay"—the first word he had spoken since his arrival. Some money was given to him. This treatment effected an instantaneous cure. It was repeated in moderate though regular doses, and Ulimengo, a bright and intelligent lad, was found to be useful in all kinds of tasks.

Many natives suffering from ailments other than sleeping sickness asked for treatment. Dr. Kleine says that they make hardly any distinction between different diseases or between different medicines. Illness is simply illness to them, and any medicine is a cure for all diseases. It was impossible to make them understand that there were specific complaints and specific remedies.

SOURCES OF SUPPLY OF DIVI-DIVI.

Divi-divi is the native and commercial name for the dried seed pods of *Caesalpinia coriaria*, a small tree indigenous to tropical America. This tree grows to a height of 20 to 30 feet, lives approximately 100 years, and bears fruit from its seventh year, though not reaching full development until its twentieth year. A mature tree will, under favourable conditions, yield as high as 300 pounds of pods a season. The pods are 2 to 3 inches long, three-fourths inch broad, one-eighth inch thick, and very smooth. While drying they become curiously curved, frequently assuming an S shape. The tannin in these pods is exceedingly astringent, containing a large proportion of ellagitannin and gallotannin, also a considerable amount of oily and mucilaginous matter.

The tannin content ranges from 40 to 45 per cent. This tannin occurs mainly in the tissues of the pod close to the outer skin, rather than in the seeds, which contain but little. A representative analysis of the pods is: Water, 13.5 per cent; tannin, 41.5 per cent; non-tannins, 18 per cent; ash, 1.6 per cent; and insoluble matter, 25.4 per cent. Every 100 parts of tannin contain 20.2 parts of carbohydrates.

Great care must be taken in the handling of pods for export, for, as the tannin content of the pod occurs immediately under the epidermis, in the form of a white powder, any abrasion of the skin will result in loss of tannin. It is also essential that the pods be packed in fine bags rather than in those of coarse-grained material, which would permit the powder to sift through and become lost in transit.

Divi-divi readily adapts itself to separation into the concentrated extract form. Owing to the presence of a large proportion of carbohydrates and the foreign substance previously referred to, both the extract and the ordinary solutions for tanning purposes are subject to fermentation. Throughout the process of fermentation a deep colouring matter is developed which imparts to leather unsightly dark stains. The problem of effectively avoiding this fermentation has yet to be solved, although the risk can be materially lessened by the use of antiseptics.

The use of divi-divi in the manufacture of leather was known to the Spaniards as far back as 1769, having been first imported into Spain from Caracas in that year. It advanced steadily in European favour during the succeeding 100 years, at the close of which period its use as a tanning agent had become widely extended. It was not, however, until 1915, when tanners found it necessary to utilize all available sources of tannin to meet the war demand for leather, that the use of divi-divi in the United States could be regarded as worth while.

A survey of the sources of supply of divi-divi has been made and published by the Research Division of the United States Department of Commerce, from which the following particulars have been extracted:—

Venezuela has long been regarded as the world's most important source of divi-divi. The general development and economic success of this industry are shown in the export statistics of that product. During the period 1908-1921, Venezuela's exports of divi-divi averaged 6,610 metric tons annually. This average includes yearly exports as high as 10,902 tons in 1911 and as low as 3,956 tons in 1920 and 2,849 tons in 1921; omitting the two low years, the average of the preceding 12 years was 7,145 metric tons. Should a greater demand for this product be created among tanners, Venezuela could increase its output several fold through harvesting of full crop and systematic cultivation. At present only that part of the crop most readily available is assembled in sufficient quantities to fill market requirements.

Before the war, Germany was Venezuela's best market for divi-divi, which is utilized as both tanning agent and dyestuff. Out of a total of 5,371 metric tons exported by Venezuela in 1913, Germany took 5,092 tons. Since 1915, however, the United States has become the principal purchaser.

The high cost of transportation during the war and the desire to eliminate all possibility of waste led to the establishment of two extract factories in Venezuela, located at the ports of Porlamar and La Guaira. At each of these plants the pure tannin is extracted from the pods—by means of a patented process into which neither heat nor the use of any chemical composition enters—and put up in pressed tablets. It is claimed that the tablets, or cakes, ready for export contain an average of 80 per cent. tannic acid and 16 per cent. tannic glucose. No export figures of divi-divi extract are available.

Colombia ranks second to Venezuela as a source of divi-divi. The estimated total annual output is 7,500 tons, the bulk of which is produced in the Goajira Peninsula and exported through the port of Rio Hacha to Curacao for trans-shipment. Decreased demands during the post-war industrial depression produced a general dulness in Colombian trade in divi-divi rather than lessened supplies; but, judging by recent United States imports from Curacao (the greater proportion of which came originally from Rio Hacha), Colombia must be renewing its former activity in this product.

The Dominican Republic's exports of divi-divi formerly exceeded 2,000,000 pounds annually, almost all of which was produced on the arid lands of the Province of Monte Cristi. The output, however, has been seriously affected in recent years by the presence of a species of orchid, which lives as a parasite on the divi-divi tree, frequently killing it, and in every case reducing the yield of pods. Until measures are introduced to eliminate this pest no great increase in exports may be anticipated. The present annual production of the Dominican Republic and Haiti is estimated at 1,500 tons.

The Dutch West Indies have an annual output of about 2,000 tons; all shipments in excess of this amount originate in Venezuela and Colombia.

As a general rule divi-divi pods are leached by the tanner. If passed through a disintegrator the pods are readily broken and the rich tannin powder sifted out, which is mostly soluble in water. A liquid extract containing 25 per cent. tannin is an article of commerce.

Divi-divi is rarely used alone, because the leather thus produced is strongly affected by atmospheric conditions, being soft and spongy in damp weather and lacking pliability in periods of drought. To counteract these tendencies divi-divi is usually mixed with other tanning materials. If used in strong liquors it yields a heavy and firm leather. Ordinarily it is employed as a substitute for gambier in the dressing of leather, and in the rapid drum tannage of light leathers, through means of which an excellent colour may be obtained. Occasionally, its use in connexion with leather is merely as a dye.

GENERAL NOTES.

The Physical Society of London: Jubilee Celebrations.—The Physical Society of London, which held its first meeting on March 21st, 1874, is arranging to celebrate its Jubilee from March 20th to 22nd next. The preliminary programme of the proceedings in connexion therewith is given below. Fellows of the Society are invited to be present at the Jubilee meetings. According to present arrangements no tickets will be required for this purpose. Thursday, March 20th, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C.2: 2.30 p.m.—Opening of Exhibition of Apparatus; 3.0 p.m.—Reception; 3.45 p.m.—Delivery of the Guthrie Lecture by M. le Duc de Broglie on "Photo-electric Effects, in the case of High Frequency, and Allied Phenomena." Friday, March 21st, at the Institution of Electrical Engineers: 4-5.30 p.m. and 6-7.30 p.m.—Reminiscences by Original Fellows and other Fellows of long standing. Saturday, March 22nd, Continuation of Exhibition at the Institution of Electrical Engineers: 7 for 7.30 p.m. Banquet (for Fellows and guests only).

Whaling in Ross Sea.—According to the *Times Trade and Engineering Supplement*, a base for a Norwegian Whaling Syndicate is being established at Hobart, Tasmania, for the conduct of whaling operations in the Ross Sea. Five whalers are already assembled at Hobart, awaiting the arrival of a factory ship from Norway. The expedition carries a licence granted by the British Government, but the operations will be under the surveillance of the New Zealand Government, which now controls the Ross Sea Dependency. The terms of the licence restrict operations to whales and fur seals, and the expedition will not be permitted to interfere with other forms of animal or fish life. A royalty will be collected by the New Zealand Government on all whale oil won. As soon as the factory ship arrives, the fleet will take in stores and proceed to the Ross Sea. The vessels will return to Hobart after a few months' operations, when the ice sets in, and despatch their products to home markets. More extensive operations will follow on the next trip.

Porcelain and Pottery in Japan.—Since the European War the porcelain and pottery industry in Japan, says *Finance and Commerce*, of Shanghai, has been rapidly emerging from the stage of a household industry and has been modernised, so that factories with modern equipment now exist in various centres. In the production of foreign style crockery for export, Aichi-ken, where Seto, the most flourishing centre of this industry in Japan, is situated, ranks first, its total output, domestic and foreign consumption combined, amounting to 32 million yen, or about 50 per cent. of the total for the whole country.

The West Indian Agricultural College.—The West Indian Agricultural College, which is Imperial in scope and interests, was formally opened by His Excellency Sir Samuel H. Wilson, K.C.M.G., K.B.E., C.B., R.E., Governor of Trinidad and Tobago, on October 16, 1922. The College, at present housed in provisional buildings of a substantial character, is situated in spacious grounds at St. Augustine, eight miles to the eastward of Port of Spain. Easy access to it is afforded by the Government Railway and the Eastern Main Road, both of which pass the college grounds. The object of the college is to afford general instruction in tropical agriculture, to give opportunities for thorough training in the science and practice of the subject to those students intending to become tropical planters, investigators or experts in different branches of agricultural science or technology, and at the same time, to provide facilities for the study of tropical agricultural subjects on the part of graduates from other universities and colleges who desire to acquire knowledge of these subjects in tropical surroundings. It cannot be too widely known that the college is open to students and post graduates from every part of the Empire. Copies of the prospectus can be obtained from Mr. A. G. Howell, the West Indian Agricultural College, St. Augustine, Trinidad, B.W.I., or from Mr. Algernon Aspinall, C.M.G., 14, Trinity Square, London, E.C.3.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

March 5.—Major-General Sir Fabian Ware, K.C.V.O., K.B.E., C.M.G., C.B., Vice-Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

March 12.—Alan A. Campbell Swinton, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.) Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., will preside.

March 19.—R. L. Robinson, Member of the Forestry Commission, "The Forests and Timber Supply of North America." Lord Lovat, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., will preside.

March 26.—Neal Green, "The Fishing Industry and its By-Products." Professor E. W. MacBride, D.Sc., F.R.S., will preside.

April 2.—Sir Lynden Macassey, K.B.E., "London Traffic."

April 9.—Frank Hope-Jones, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." PROFESSOR C. VERNON BOYS, F.R.S., will preside.

APRIL 30.—BRIGADIER-GENERAL SIR HENRY MAYBURY, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, 'Roads."

MAY 5 (Monday).—T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MAY 7.—J. ROBINSON, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

MAY 14.—

MAY 21.—PROFESSOR C. VERNON BOYS, F.R.S., "Calorimetry." (Trueman Wood Lecture.)

MAY 28.—MRS. ARTHUR MCGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons at 4.30 o'clock :—

MARCH 21.—OTTO ROTHFELD, I.C.S., "Progress of Co-operative Banking in India."

MAY 2.—JOCELYN F. THORPE, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced :—

BHUPENDRA NATH BASU, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Monday or Tuesday afternoons at 4.30 o'clock :—

MARCH 4.—THE HON. T. G. COCHRANE, D.S.O., "Empire Oil: The Progress of Sarawak." THE RT. HON. LORD BEARSTED will preside.

MAY 27.—C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

June 16.—C. V. Corless, M.Sc., LL.D., "The Mineral Resources of Canada: The Pre-Cambrian Area."

CANTOR LECTURES.

EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

Syllabus.

LECTURE II.—MARCH 3.—The inter-relation of therms in the form of gas and tar and the process conditions which affect their distribution. Further principles underlying high yields of gaseous therms. The chemistry and economics of tar cracking.

LECTURE III.—MARCH 10.—The trend of developments in carbonising processes. The de-ashing of coal and other factors tending to increase the value of the therm in the form of coke.

COBB LECTURES.

Monday evenings, at 8 o'clock :—

DR. T. SLATER PRICE, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, MARCH 3 .. Royal Institution, Albemarle Street, W., 5 p.m. Monthly meeting.

Farmers' Club, at the Surveyors' Institution, 12, George Street, S.W., 4 p.m. Dr. A. G. Voelcker, "The Liming of Land."

Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 5.30 p.m. Mr. G. H. Thomas, "Air Transport and its Uses."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 7 p.m. (Graduates' Section). Lieut.-Col. E. Kitsin Clark, "Literature and Engineering."

Chemical Industry, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1. Messrs. R. Whymper and A. Bradley, "The setting of cacao butter with special reference to the development of 'Bloom' on chocolate." 2. Messrs. W. J. Powell and H. Whittaker, "The determination of Pentosans in wood cellulose."

Engineers, Society of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Mr. J. Jackson, "Development of Methods for the Collection and Disposal of House Refuse."

Electrical Engineers, Institution of, Victoria Embankment, W.C., 7 p.m. (Informal meeting). Mr. R. D. Spur, "The Selection and Location of Converting Plant for supplying D.C. Networks."

University of London, University College, Gower Street, W.C., 5.30 p.m. Sir Harry Stephen, "Criminal Law." (Lecture II.)

5.15 p.m. Mr. A. S. Parkes, "The Mammalian Sex-Ratio." (Lecture VI.)

At King's College, Strand, W.C., 5.30 p.m. Rev. C. F. Rogers, "Ecclesiastical Music." (Lecture V.)

5.30 p.m. Dr. R. S. Seton-Watson, "A Survey of Bohemian History." (Lecture V.)

TUESDAY, MARCH 4 .. Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

United Service Institution, Whitehall, S.W., 3.30 p.m. Anniversary meeting.

Alpine Club, 23, Savile Row, W., 8.30 p.m. Mr. R. W. Lloyd, "Le Col dit Infranchissable."

Metals, Institute of (North-East Coast Section), Armstrong College, Newcastle-on-Tyne, 7.30 p.m. Mr. H. J. Young, "Alloys for Use with Superheated Steam."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Prof. M. von Rohr, "Contributions to the History of the Photographic Objective in England and America, 1800—1875."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. J. Barcroft, "The Respiratory Pigments in Animal Life." (Lecture IV.)

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. J. H. Helweg, "Modern Danish Lyrics, 1870—1920." (Lecture V.)

At King's College, Strand, W.C., 5.30 p.m. Sir Bernard Pares, "Russia before Peter the Great to 1861." (Lecture VII.)

WEDNESDAY, MARCH 5 London County Council, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Sir Napier Shaw, "Modern Meteorology." (Lecture II.)

Oriental Studies, School of, London Institution, Finsbury Circus, E.C., 5 p.m. Rev. W. S. Page, "The Songs of Rabind-Ranath Tagore."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. J. S. Duckers, "Human Nature in Industry."

United Service Institution, Whitehall, S.W., 3 p.m. Col. the Hon. M. A. Wingfield, "The Supply and Training of Officers for the Army."

Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. (Wireless Section). Commander J. A. Slee, "Development of the Bellini-Tosi System of Direction Finding in the British Mercantile Marine."

Public Analysts, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1 (a). Mr. G. D Elsdon, "The Composition and Examination of Beef and Malt Wine;" (b) "The Determination of Coconut Oil in Margarine." 2. Dr. J. C. Drummond and Mr. H. J. Channon, "Effect of Fatty Diet on the Composition of Butter Fat." 3. Mr. G. D. Elsdon, "What is Bondon Cheese?" 4. Mr. T. R. Hodgson, "Cream Cheese" 5. Messrs. R. T. Thompson and J. Sorley, "Some Facts on the Composition and Decomposition of Eggs."

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. I. C. Gröndahl, "Contemporary Norwegian Literature." (Lecture V.)

6 p.m. Prof. K. Pearson, "The Current Work of the Biometric and Eugenics Laboratories." (Lecture IV.)

6 p.m. Miss Julia Bell, "Colour Vision and Colour Blindness."

At King's College, Strand, W.C., 5.30 p.m. Dr. G. F. Hill, "The Artistic Background of Mediæval History—Coins."

At the University, South Kensington, S.W., 5 p.m. Sir Frederick Bridge, "Some Shakespearian Studies." (Lecture IV.)

THURSDAY, MARCH 6 Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Major W. S. Tucker, "Sound Detection."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Linnean Society, Burlington House, Piccadilly, W., 5 p.m.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m.

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. I. Björkhagen, "Modern Swedish Prose Authors." (Lecture V.)

5.30 p.m. Dr. C. Pellizzi, "Campanella." (In Italian.)

At King's College, Strand, W.C., 5.30 p.m. Rev. F. R. Barry, "The New Testament Perspective."

5.30 p.m. Dr. A. R. Pastor, "Spanish Mysticism." (Lecture II.)

5.30 p.m. Prince D. S. Mirsky, "The History of Russian Literature." (Lecture VII.)

At St. Thomas' Hospital, Albert Embankment, S.E., 5 p.m. Dr. J. A. Murray, "Cancer." (Lecture III.)

At St. Mary's Hospital Medical School, Praed Street, W., 5 p.m. Prof. B. J. Collingwood, "Blood." (Lecture III.)

British Decorators', Institute of, Painters Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. W. H. Cantrill, "A Pilgrimage to the Hill Towns of Umbria."

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Dr. P. B. Billard, "The New Examiner."

London County Council, the Geffrye Museum, Kingsland Road, E., 7.30 p.m. Mr. C. A. Hindley, "Fabrics used in Upholstery."

Mechanical Engineers', Institution of (Scotch Section), Royal Technical College, Glasgow, 7.30 p.m. Mr. R. W. Wilson, "Repair and Upkeep of Pneumatic Tools" (Midland Section), The University, Birmingham, 7.30 p.m. Dr. F. C. Lea, "Fatigue of Materials."

Royal Institution, Albemarle Street, W., 5.15 p.m. Dr. J. S. Flett, "Modes of Volcanic Action." (Lecture I.)

FRIDAY, MARCH 7 Royal Institution, Albemarle Street W 9 p.m. Dr. W. Rosenhain, "The Inner Structure of Alloys."

Philological Society, University College, Gower Street, W.C., 5.30 p.m. Dr. C. T. Onions, "Dictionary Evening."

Geologists' Association. University College, Gower Street, W.C., 7.30 p.m.

Aeronautical Engineers, Institution of, at the Engineers' Club, Coventry Street, W., 6.30 p.m. Mr. L. Rowland, "Braided Rubber Shock Absorber Cord for Aircraft."

Timber Trade Lectures, Council Chamber, London Chamber of Commerce, Oxford Court, Cannon Street, E.C., 6.30 p.m.

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. H. Lambert, "A Consideration of the Technical and Artistic Qualities of Printing Processes."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 7 p.m. (Informal Meeting). Commander G. E. C. Damant, "Recovering Gold from the Laurentic."

Metals, Institute of (Local Section), at the University, St. George's Square, Sheffield, 7.30 p.m. Mr. S. Field, "Some Aspects of Alloy Plating."

University of London, University College, Gower Street, W.C., 5.15 p.m. Lord Justice Atkin, "The Origin and Development of Law in relation to Civic Life."

5 p.m. Prof. E. A. Gardner, "The History of Ancient Sculpture."

At King's College, Strand, W.C., 5.30 p.m. Prof. R. W. Seton-Watson, "The Rise of Nationality in the Balkans" (Lecture VII.)

5.30 p.m. (Shakespeare Association). Miss Z. Vengerova, "Hamlet in Russia."

At the Bedford College for Women, 5.15 p.m. Prof. F. Soddy, "How Physical Science has altered the Economics of Life."

SATURDAY, MARCH 8 Royal Institution, Albemarle Street, W., 3 p.m. Prof. Sir E. Rutherford, "Properties of Gases in Vacua." (Lecture I.)

London County Council, at the Horniman Museum, Forest Hill S.E., 3.30 p.m. Dr. H. S. Harrison, "Man's Early Discoveries and Inventions."

Journal of the Royal Society of Arts.

No. 3,720. VOL. LXXII.

FRIDAY, MARCH 7, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

2 APL 1924
A. R. I. P. U. S.

NOTICES.

NEXT WEEK.

Monday, March 10th, at 8 p.m. (Cantor Lecture.) **Edward Victor Evans**, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." (Lecture III.)

Wednesday, March 12th, at 8 p.m. (Ordinary Meeting.) **Alan A. Campbell Swinton**, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.) **Sir Dugald Clerk**, K.B.E., D.Sc., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On **Monday Evening, March 3rd**, 1924, **Mr. Edward Victor Evans**, O.B.E., F.I.C., delivered the second lecture of his course, "A Study of the Destructive Distillation of Coal."

The lectures will be published in the *Journal* during the summer recess.

DOMINIONS AND COLONIES SECTION.

Tuesday, March 4th, 1924; **The Rt. Hon. Lord Bearsted** in the Chair. A paper on "Empire Oil: the Progress of Sarawak," was read by **The Hon. T. G. Cochrane**, D.S.O.

The paper and discussion will be published in a subsequent number of the *Journal.*

TWELFTH ORDINARY MEETING.

Wednesday, February 27th, 1924; **Sir Robert Blair**, LL.D., Education Officer, London County Council, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Bruce, Oswald B., Weston-super-Mare.
Haunz, Charles F., M.Am.Chem.S., Buffalo, New York, U.S.A.
Howgrave, Arthur Atherfold, London.
Porro, Thomas Joseph, Tacoma, Washington, U.S.A.
Shallenberger, Professor Garvin Dennis, Montana, U.S.A.
Vaid, Bakhshi Dina Nath, Rawal Pindi, India.

The following candidates were duly elected Fellows of the Society:—

Franzen, Raymond, Ph.D., Berkeley, California U.S.A.
McCall, William A., Ph.D., New York City, U.S.A.
Mattu, Pandit Jagar Nath, Srinagar, India.
Shaw, Professor Frederick William, B.S., M.D., Rolla, Missouri, U.S.A.

A paper on "The Use of Psychological Tests in the Selection of a Vocation" was read by **Dr. Charles S. Myers**, C.B.E., M.D., F.R.S., Director of the National Institute of Industrial Psychology.

The paper and discussion will be published in a subsequent number of the *Journal.*

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1924 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 22nd, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

1864, Sir Rowland Hill, K.C.B., F.R.S.
1865, His Imperial Majesty, Napoleon III.
1866, Michael Faraday, D.C.L., F.R.S.
1867, Sir W. Fothergill Cooke and Sir Charles Wheatstone, F.R.S.
1868, Sir Joseph Whitworth, LL.D., F.R.S.
1869, Baron Justus von Liebig.
1870, Vicomte Ferdinand de Lesseps, Hon. G.C.S.I.
1871, Sir Henry Cole, K.C.B.
1872, Sir Henry Bessemer, F.R.S.
1873, Michel Eugène Chevreul, For. Memb. R.S.
1874, Sir C. W. Siemens, D.C.L., F.R.S.

1875, Michel Chevalier.

1876, Sir George B. Airy, K.C.B., F.R.S.

1877, Jean Baptiste Dumas, For. Memb. R.S.

1878, Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

1879, Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.

1880, James Prescott Joule, LL.D., D.C.L., F.R.S.

1881, Professor August Wilhelm Hofmann, M.D., LL.D., F.R.S.

1882, Louis Pasteur.

1883, Sir Joseph Dalton Hooker, K.S.C.I., C.B., M.D., D.C.L., LL.D., F.R.S.

1884, Captain James Buchanan Eads.

1885, Sir Henry Doulton.

1886, Samuel Cunliffe Lister (afterwards Lord Masham).

1887, Her Majesty Queen Victoria.

1888, Professor Hermann Louis Helmholtz.

1889, John Percy, LL.D., F.R.S.

1890, Sir William Henry Perkin, F.R.S.

1891, Sir Frederick Abel, Bt., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

1892, Thomas Alva Edison.

1893, Sir John Bennet Lawes, Bt., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

1894, Sir Joseph (afterwards Lord) Lister, F.R.S.

1895, Sir Isaac Lowthian Bell, Bt., F.R.S.

1896, Professor David Edward Hughes, F.R.S.

1897, George James Symons, F.R.S.

1898, Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S.

1899, Sir William Crookes, O.M., F.R.S.

1900, Henry Wilde, F.R.S.

1901, His Majesty King Edward VII.

1902, Professor Alexander Graham Bell.

1903, Sir Charles Augustus Hartley, K.C.M.G.

1904, Walter Crane.

1905, Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.

1906, Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.

1907, The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.

1908, Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.

1909, Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.

1910, Madame Curie.

1911, The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., F.R.S.

1912, The Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S.

1913, His Majesty King George V.

1914, Chevalier Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.

1915, Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S.

1916, Professor Elias Metchnikoff.

1917, Orville Wright.

1918, Sir Richard Tetley Glazebrook, C.B., Sc.D., F.R.S.

1919, Sir Oliver Joseph Lodge, D.Sc., LL.D., F.R.S.

1920, Professor Albert Abraham Michelson, For. Memb. R.S.

1921, Professor John Ambrose Fleming, D.Sc., F.R.S.

1922, Sir Dugald Clerk, K.B.E., D.Sc., LL.D., F.R.S.

1923, Major-General Sir David Bruce, K.C.B., D.Sc., LL.D., F.R.C.P., F.R.S., and Colonel Sir Ronald Ross, K.C.B., K.C.M.G., D.Sc., LL.D., M.D., F.R.C.S., F.R.S.

PROCEEDINGS OF THE SOCIETY

TENTH ORDINARY MEETING.

Wednesday, February 13th, 1924.

Sir Aston Webb, K.C.V.O., C.B., P.R.A., in the Chair.

The following paper was read :—

THE TREATMENT OF THE DEATH-WATCH BEETLE IN TIMBER ROOFS.

By H. Maxwell-Lefroy, M.A.,

Professor of Entomology, Imperial College of Science and Technology.

During the last ten years it has been realised that the past, actual or future attacks of the death-watch beetle on all structural timber are of real importance, and if we are to hand on to later generations the fine timber constructions of the past four or five centuries, some definite steps must be taken to deal with this insect.

There has been some public interest in this problem, but it is much more important that there should now be some definite standardised technical knowledge; those who are concerned with the preservation of buildings have no means of knowing how to act.

In this lecture to-night, it is not proposed to attempt to dogmatise in regard to methods which can be adopted; but rather to describe the present state of the problem, in the hope that discussion may arise, and that out of the collected craft of architects, engineers, chemists and entomologists, some methods may be found that will aid those who are concerned in this question.

The position as regards the beetle now comes under three heads :—

(1.) It has attacked buildings, probably from the time they were built, done certain definite damage (observable, of course, only in those that have remained intact) and ceased. Why the infestation has ceased is a point of great interest: a great many factors are concerned, and I think no one is in a position to say anything definite; but it is clearly a point to keep in mind.

(2.) Roofs, floors, and other constructional timbers are now being destroyed, either from their original state or after reconstruction; there is here a definite infection in progress at the moment, with steady increase of damage up to a point.

I do not propose to mention any buildings which are in this state, but I never enter a building of even partly wooden construction without apprehension that it is now attacked. Fortunately cases of past attack are more common than those of present actual attack; but it is only reasonable to warn those responsible for the care of buildings that examination often discloses actual infestation by living insects; and there is no doubt that a great deal of actual destruction is now in progress. I sympathise with those who will have no examination made for fear of the disclosure of actual attack and consequent cost of treatment, but it is useless to ignore the fact that there is a great deal of damage in progress now.

(3.) The third point is as to infestation of new timbers in roofs, floors, and similar constructional timbers; it is, unfortunately, true that renovations are done with infested wood, and that buildings are becoming infested from this source, which otherwise would remain free. I know of cases at present in which this has occurred; and it does seem a pity to infest a building by bringing into it timber containing the beetle. If greater publicity secured only this, that those who restore did not infest, then great benefit would follow.

In treating of the death-watch beetle to-night, our main interest lies in the insect as such, and in any consequent precautions that can be taken; we may, therefore, first consider the essential facts of the insect's life and habits, so far as these are known.

The death-watch beetle is the larger of the beetles which are found breeding in wood in buildings, furniture, etc.; normally it lives wild in the dying or dead trunks and larger branches of oak, willow, hawthorn, hornbeam, alder beech; it is recorded from maple and sycamore; it has under certain conditions been found in pine in buildings.

In the wild, the beetles emerge on the bark during the evenings of the early summer; the females lay eggs, soft, oval, white, by means of the long ovipositor: it is not certain, but probable, that each egg is laid in a crack or other crevice, away from the light: the beetles themselves do not burrow or destroy the wood; and normally they perish probably by midsummer. The eggs hatch probably within a definite period between two and four weeks; the grub then tunnels inwards, eating the solid wood, usually in the outer sapwood; it feeds the whole summer, rests during the winter, feeds the second summer, and may then become a chrysalis; if so, it becomes a beetle in probably three or four weeks, which rests as an immature beetle and does not emerge till May, two years from the time it was an egg. Under certain conditions, this period of two years may be three, the grub resting over the second winter as a grub, feeding during the next summer and becoming a chrysalis, and then a beetle only at the end of the third summer; one may tabulate the facts like this:—

May-June	1920	Beetles out.	Beetles out.
June	1920	Eggs.	Eggs.
July	1920	Grubs.	Grubs.
August	1921		
September	1921	Pupæ.	Grubs.
October	1921	Resting Beetles.	Grubs.
May	1922		
May	1922	Beetles out.	Grubs.
June	1922	—	Pupæ.
July	1922	—	Beetles resting.
to May	1923		
May	1923	—	Beetles out.

This table may be taken as approximate—Westwood states that the grub feeds for three years and it may feed longer. But the point to remember is that the egg and chrysalis stage are probably definitely short, while the grub and beetle stage may take a much less definite time, 18 to 36 months for the former; eight to 12 or 15 months in the latter.

The only visible stage of the beetle is in its adult form, when it comes out upon the bark at evening; and all three immature stages are spent entirely in the tree.

In the wild, the insect is attacked by another beetle, which hunts it down in its galleries; unfortunately, this is comparatively rare, and has apparently only been found in trees, not in buildings.

An interesting point is that the grub, which does the tunnelling, has within its stomach an organism of a microscopic kind similar to a yeast, which is apparently a necessary factor in the digestion of the wood: this organism exists also in the adults, is probably deposited on the egg when it is laid, so that the grub becomes infected with what is apparently a necessary adjunct to its digestion: similar instances are known in related woodboring grubs; and the point may ultimately prove to be of more than academic interest, as one might well be able to sterilise the egg of its yeast without killing the egg, but still make life in the timber impossible for the grub.

We are concerned with the natural habits of the beetle in its wild state, because it is the basis from which we start to deal with the pest in a building; and the three important modifications of habits which are important in its indoor life are:—

(1) The alteration in emergence;

(2) The date of emergence;

(3) The manner of feeding of the grub.

In large timbers in buildings beetles do not necessarily emerge to the outside, if there are spaces within into which they can get: a colony of beetles may, therefore, continue work deep inside big roofs, and not emerge as beetles at all.

Secondly, under the different temperature conditions of a building, emergence of the beetles or the existence as a beetle may occur at any time of the year; in unwarmed buildings the beetle behaves as it does out of doors, emerging in early summer mainly.

Thirdly, the grubs will tunnel not in the sap wood only, but into solid heartwood, or from one timber into another contiguous one regardless of the relative position of the grain of the two timbers: this last point is an important one in dealing with timber in buildings; and it is probably the cause of the occurrence of the beetle in pine and soft wood.

In putting before you the problem of dealing with this pest, I am trying to concentrate on points which concern its treatment: much has been said and written about how the wood is destroyed, the appearance of wood, the effects from the architectural and engineering point of view, the historical interest of buildings in which the beetle has worked. This is not the place to list the buildings which we definitely know to have suffered or to be now suffering, nor to describe the damage in these buildings admittedly caused by this insect: I think all who have been concerned with the care of old timber roofs know that the damage may be extremely serious, and so much is common knowledge on this point that I need not stress it; but there are three points which need special consideration: How does the roof become infested? Why does the attack stop? How can you recognise an attack deep in an inaccessible structure?

The way in which an attack commences is of great interest, and I offer you three conjectures; they are:—

(1.) That the original timbers are infested when put in place;

(2.) That at any time after construction, the insect is brought in with renewals, repairs, or fresh timber objects, such as floors, pews, etc.; and

(3.) The insect itself comes in.

We have, unfortunately, no knowledge of the third; beetles do fly and may come in to buildings; but it is unlikely and ill accords with what we know of the beetle's habits. All the cases I have seen have pointed to the use of originally infested wood, or the introduction at some time of infested wood for repairs, renewals, church furniture, flooring, or the like. We have one definite case of an oak floor, put in forty years ago, which is now very heavily infested and from which the pest has infested also pews and other furniture: from this case we can judge that other buildings are now in a state that corresponds with an infection between 40 and 80 years ago. In one of the most beautiful buildings in England, the roof was definitely repaired with infested wood within the last thirty years: and I think in most cases one can get evidence of this sort, pointing either to original or to later infection in this way.

The next point is, why an attack ceases: it undoubtedly does cease without reference definitely to anything that has been done to stop it; these cases show an abundance of attack (which one can date for instance, with reference to definite emergences of beetles through a layer of lime wash put on at a known date), abundant further timber to attack, and no evidence of actual attack at the present date. What has happened? Have the beetles come out, flown away and gone elsewhere? Have the grubs perished inside? Has the wood become too dry, or has the yeast perished? We do not know, but we must take account of the phenomenon. A great sum of money has been spent on buildings in which all attack had ceased: and cases are under observation now where the assumption is that no further attack is proceeding, and the risk is being definitely taken of doing nothing at present to deal with the pest, merely on these grounds.

Lastly, I must deal with one point, the evidence of attack in progress in timbers inaccessible for examination: there are two sources of evidence; one is the holes in the wood from which the beetles have emerged, and which are unmistakeable; the other is the absolutely characteristic oval flattened pellets of excreta, which may pour out of a big roof joist, and which indubitably prove the presence at some time of the beetle. If the holes, for instance, come through a layer, or the timber put on at a known date, then attack was in progress since that date: if absolutely no pellets are found below joists, for instance, over a ceiling that has not been disturbed or cleaned for a definite period, then one has definite evidence that an attack is not in progress.

In each case, one has to judge by this kind of evidence as to what has occurred, or is now occurring: I wish there were time to discuss individual buildings, but it is not our object to-night to focus attention on any but the general principles of treatment.

TREATMENT.

(1.) Prevention of Infection.

The first and most obvious protection is to make sure that nothing is brought into a building that will bring in the insect, whether it be worked or unworked timber to be used for renewal or repair, or wood furniture or flooring. There is, unfortunately, evidence that quite ancient roofs, not hitherto infected, have been infected in this way, and it seems reasonable to make sure that every scrap of timber brought in shall be free: unfortunately, even apparently sound wood may be infested with eggs or young grubs without any obvious evidence, or beetles may be brought in clinging to the timber, particularly if it is to be worked further within the building. The remedy is the obvious one, to treat every surface when brought in so as to destroy any surface infection, to treat every piece of wood, when it is finally shaped and before it goes into position, so that if infected it is freed, and if not, the beetle cannot possibly emerge from that piece of wood. Judging from cases we have had, much infestation has come from renewals or repairs over the last 40 to 80 years, and this is still a source of infection whose effects will show themselves within the next forty to sixty years.

(2.) Surface Treatment.

We then come to treatment of wood *in situ*, where it is possible to get at nearly all or absolutely all surfaces, and where any damage going on can be located, minimised or stopped by a surface treatment. This means that if an attack is going on, the beetles either cannot get out or cannot get in to a fresh surface.

I know of no other treatment but a chemical one: one cannot heat timbers to 130° F. when *in situ*; one cannot, as a rule, use a vapour or any electrical action; and we know so little of the beetle that we have no way of enticing it out.

The ideal surface treatment should have these properties:—

(1.) Penetration, due to wetting power (*i.e.*, to low surface tension in regard to the interfacial action of liquid and wood): this means only that the liquid will wet evenly all cracks, shakes, crevices, etc., not that it will actually penetrate across the grain into the wood itself.

(2.) Killing power on eggs or grubs at the surface.

(3.) A permanent poison to emerging beetles.

(4.) Deterrent to wandering beetles seeking shelter or a place to lay eggs.

(5.) Permanent, not chemically changing or altering in colour in course of time.

(6.) Reasonably non-inflammable.

(7.) Not a virulent poison to man, while in application.

(8.) Not a permanent virulent poison (which could for instance come off choir stalls or lecterns on to moist fingers: corrosive sublimate is a case in point which has been used in this way).

(9.) Not be a varnish solvent for cases where varnished or polished wood is concerned.

(10.) Comparatively simple and cheap.

(11.) Not too smelly.

(12.) Give off a vapour toxic to insects inside the wood.

(13.) Not corrosive to metal used in strengthening or bolting up.

(14.) Applicable as a liquid, as a spray, swab or cream.

(15.) Not form a dust on drying which will eventually in time dust out.

(16.) Not affect the colour of the wood.

We now come to the domain of the chemist; and I fear that the correlation of chemistry and entomology at this point is a new one. In the days when Westminster Hall was being considered, we arrived at this compromise: a mixture mainly of dichlorbenzene, which was a non-inflammable liquid, which had good penetrating power, was a good insect killer, and in which was dissolved about 8 per cent. of soap, paraffin wax, cedar-wood oil. The paraffin wax is a changeless substance, preventing dusting out, holding in the soap, coating the eggs, forming a definite fine film that beetles dislike; the soap is a definite poison, though harmless; the cedar-wood oil was meant as a temporary local deterrent against infection from another part of the building, since the whole building could not be treated at once. I mention this mixture as it has been quoted, but you must remember that as the roof was being rebuilt as a steel roof, it did not really much matter if the beetle were stopped or not, and also that this mixture has not been adhered to, apparently the cedar-oil and the paraffin wax both being subsequently eliminated, if available information is correct.

But much work has been done since then, and particularly in two directions; very stable and permanent soaps, which are more poisonous, have been made with metallic elements, such as barium, zinc, etc., which can also be emulsified with paraffin wax and other ingredients in water as a medium: it is cheaper to use water to the extent, say, of 80 to 85 per cent., if it will carry paraffin wax, a metal soap and a deterrent oil. A typical formula which I suggest is as follows:—

Zinc, or Barium Oleate ..	3
Cedar Wood Oil	3
Soap	1
Paraffin Wax	10
Water	83

This liquid is applied to surfaces with a brush or spraying machine: it leaves a film of the wax, soap and metallic oleate, invisible, not affecting colour or varnish, not dusting out, not a human poison. Where colour is immaterial one might use a copper oleate: one can add a volatile poison, such as dichlorbenzene, or one of those discussed below. In considering this, one must remember that one cannot, as a rule, use creosotes, tar oils, arsenic, or mercury; a common recommendation was corrosive sublimate in spirit, but it is very deadly to human beings, both when applied and thereafter, and it attacks metal.

A mixture used in some buildings has been linseed oil and turpentine; this is an excellent temporary local application, the turpentine driving the insect in, but beetles come freely through it when the turpentine has gone.

Now among the immense range of possible chemicals, there is a very great variety of choice. I give the above as one out of many possible combinations, and any chemist will be easily able to see others. My point is as to whether you can get to anything that really is better than corrosive sublimate, creosote or turpentine.

Of course, there are a variety of circumstances in which the insect occurs, particularly in church furniture, and sometimes no profound chemical knowledge is required, but merely common sense. A case in point is where a few pounds spent on ordinary paraffin, as a simple treatment for infested woodblocks, would have saved an expenditure now to be faced of hundreds; but the cost of treatment with dichlorbenzene, suggested officially on an imperfect understanding of what had been done, was then prohibitive. I have seen cases where actually corrosive sublimate in spirit was the suitable method: and there are also cases where turpentine followed by linseed oil meets a simple problem.

(3.) INTERNAL TREATMENT.

Cases do arise where one may have to work on a roof *in situ* where all principal timbers are to be left undisturbed, yet where there are believed to be colonies of insects at work deep inside.

My suggestion there is that one can cautiously penetrate into infested wood with a ⅜-inch augur, screw in a pipe, and pump in a liquid which will do three things: it will give off a poisonous vapour, penetrating the burrow systems and killing larvæ; it will leave a permanent poisonous deposit against future attack; it will strengthen badly decayed wood. The difficulty is to choose a liquid embodying these points: as regards the first, it is now known that one can get liquids giving off vapours toxic to insects among these classes: the petrol paraffin and aliphatic hydrocarbons; the cyclo compounds; the benzenes, xylol hydrocarbons; the acetones and ketones; the hydrogenated phenols and naphthalenes (tetralin, hexalin, etc.); the pyridine, quinoline, and nitrogen group; the nitrobenzenes; the cyanides dissolved in alcohol; the carbon-bisulphide group; the volatile fractions from wood and coal tar distillation; the chlorinated aliphatic compounds, chlorinated benzene compounds or chlornaphthalene. These are a few of the more obvious whose killing power as liquids or vapours is now established, and among which one can choose on other grounds, and I make this general statement that these classes of substance are generally toxic to insects as vapours or liquids on the results of thousands of tests made, not on this insect, but on other insects, which we have found sufficiently uniform general killing action to warrant the belief that these kill also this grub. In some cases we have detailed tests on this grub itself, which conform generally with other tests; there are probably definite specific substances acting specially on this grub; but we need further experience before we can pick out the one liquid most toxic to the grubs that can also be used in practice.

The second point is to prevent re-infection, and one can use a wide range of poisonous substances inside wood, particularly if colour is immaterial: one would use creosote but for its smell and its lack of permanency; but I think some form of the mineral soap such as copper, barium or zinc oleate is the best. One can use an arsenic compound, but it introduces difficulties. I saw a building injected with cyanide dissolved in spirit: one could use a mercury substance; fluosilicates and silicon-ester have definite attractions. There is much to be done in this way before one can make a choice.

Thirdly, can one put in a liquid that will strengthen the much decayed timber and still carry a poison and disseminate a vapour? The simplest suggestions are cellulose acetate, synthetic resins, fluosilicates, hard waxes, silicon ester. I think it is hard to choose, and I have before me twelve different combinations of vapour, poison, filler, which have been tried. In an important case a formula is being used in which acetone dissolves cellulose acetate, zinc oleate and acetone oil; this works well in practice, *i.e.*, in actual application; and it has also been varied by the introduction of tetralin in place of acetone oil, the tetralin not having the objectionable acrid odour of the acetone oil. It is pumped in at spots judiciously chosen where there is reason to think grubs are at work; or badly decayed wood is saturated with it, to ensure complete sterilisation and to add strength. Impregnation of a system of burrows is not difficult; impregnation of solid timbers requires great time and considerable pressure; it may take hours or days to work the liquid along timber into a burrow system where the grubs are, but it can be done with comparatively simple apparatus, and its application as a method is mainly one requiring a little experience and judgment.

(4.) VENTILATION.

A last point of general treatment is one that is impossible to prove experimentally without abundant time, but frequent observation impresses it on one; it is the enormous influence of ventilation: wood that is kept well ventilated, even if attacked, will not ultimately perish. In two prominent buildings in London, of about the same date, one was attacked at the base of the principal rafters only, where they ran into the walls; the other had been attacked, but the attack had ceased, the whole timber structure being remarkably ventilated. I think that this point is continually coming up, and observation does correlate ventilation and immunity in a decisive way. Perhaps insufficient attention has been paid to this point, and perhaps there may have been cases where it would have been a sound policy to improve ventilation, to watch at intervals for evidence of attack, and to exercise patience before actually dealing structurally with a roof or floor; when an insect reproduces only at two or three year intervals, it takes a long time for an attack to develop, and one can afford, perhaps, to wait awhile and see whether improved ventilation alone will not prevent serious extension of damage.

It is not the intention of this paper to lay down methods, but rather to focus attention upon certain points, and I would like to emphasise the present position.

We are very ignorant of the beetle's life history and habits, mainly from lack of time and opportunity. My first investigator was available for only a few months; I have given such leisure time as I can in the intervals of a fairly crowded life. We have had little live material, and it would help if some one could get abundant material and give his whole time to the problem.

We badly want to get correlated the experience of those, in all parts of the country, who undertake to deal with cases of this sort; there are many such, but I know of no collected record of their experiences.

Thirdly, we do want to record for posterity what is done, so that our successors may find in the records of each institution a clear statement embodying the conditions as found, and the nature of the work done, so that they may judge by the results.

Lastly, I do think this is a serious matter that should be properly dealt with by some competent public body, so as to secure continuity and uniformity; it is novel, experimental, and not as yet on an established basis of experienced practice; we shall not see the results of the treatments experimentally done; and if the many fine timber buildings are to remain it will only be if this menace is dealt with.

I would here acknowledge the assistance I have had from Sir J. J. Dobbie and Mr. Noel Heaton on the chemical side: it was the late Sir J. Wolfe-Barry's munificence that made possible the original enquiry commenced at Westminster Hall. I have not consciously quoted from published papers, but you will find references to them in the Review of Applied Entomology.

To H.M. Office of Works I am indebted for access for some years to Westminster Hall, and also for a tree cut down for me in Richmond Park last year; and I owe thanks to those in charge of many buildings and churches for opportunities of investigation.

DISCUSSION.

Mr. William Woodward, F.R.I.B.A., was sure everyone present had been delighted to have listened to the paper, which was obviously the result of very great research. The subject was of the highest importance from the point of view of everybody connected with the preservation of buildings. He desired to mention the roofs of three buildings which had been infested with the insect, and the methods of restoration which had been adopted by the respective authorities. First dealing with the roof of Westminster Hall, everyone would be agreed that there was no finer example of carpentry work, both in regard to its design and execution; but what had been done when it was found that some of the timbers were infested with the death watch beetle? Instead of the contractor employing skilful carpenters to take out the defective timbers and to put in their places sound timbers of the same character, the officials had proceeded to insert steel girders. Why they had done so was a complete mystery to him. In the first place it was thoroughly inartistic and unarchitectural, and in the second place, steel was subject to expansion and contraction and to oxidation, which might affect the remaining timber. He did not hesitate to say that the result would be an enormous waste of public money. The work could have been done in a much more simple and inexpensive manner, and in a way which would have been more conducive to art and architecture.

His second example was that of the roof of Limehouse Church. Some time ago attention had been called to the fact that the roof of this church was being attacked by an insect. He had been shown a specimen of the insect. That roof was now being restored, and he had sent a contribution towards the cost of the work on the condition that no steel or iron was employed in that restoration.

The third roof he desired to mention was that of Middle Temple Hall. In the *Morning Post* on the 28th December there had been a very interesting article on that roof, to the effect that "Sir Aston Webb, President of the Royal Academy, Prof. Lefroy, the entomologist, and Mr. Basil Mott, the engineer, have in consultation advised a scheme of repairs which is now being carried out. It involves strengthening the highest collars with plates, and restoring some of the age-worn minor timbers, and also dressing the whole with a special gaseous preparation made by Prof. Lefroy." The word which had disturbed him on reading the article was the word "plates." He had wondered why Sir Aston Webb had ever consented to the putting in of plates. It did not say whether the plates were of iron or steel, but he assumed that they were of metal, and he had been surprised that such a great architect as Sir Aston Web had consented to the introduction of plates in the restoration of a series of collars in the roof of Middle Temple Hall.

As an architect, he considered it was a most important thing to find a remedy which would stop the ravages of these particular insects. It might be that that remedy would be found in some of the liquids of which the author had given a list in his paper. Personally he was one of those who believed that the proof of the pudding was in the eating, and he would ask the author if he would kindly take him to Westminster Hall 400 years hence in order to see the effect of one of the numerous liquids which it was proposed should be put on the roof.

Sir Frank Baines, C.V.O., C.B.E. (Director of Works, H.M. Office of Works), said it had been a great privilege to him to listen to the paper that night, because H.M. Office of Works had had valuable assistance from the author in the past with regard to the problems which they had had to face. The most important point which the author had brought out—a point which would particularly appeal to architects—was that the attack of the beetle appeared to be so universal and so prevalent that there was probably hardly a mediæval structure in this country which was not, or had not been, infected by it at some time or another. If the author had only brought out that one point he had done a great public service, because the priceless mediæval timber structures which existed to-day required expert examination and opinion as to whether they were infected by this odious little creature. One very important fact which had been brought out by the author had been confirmed by Dr. Paine, namely, the existence of that curious yeast in the stomach of the larva of the *xestobium tessellatum*. He would like to ask the author whether it would be possible for him to suggest an investigation into the question of whether the attack on the grub should proceed on the lines of destroying that yeast.

Another thing he would like to ask the author was his opinion of the real toxic effect of the first solution which had been used by H.M. Office of Works under his help and advice, namely, tetrachlorethane with trichlorethylene as a diluent. That had been used originally at Westminster Hall, but it was afterwards found to be such a virulent poison that its use had had to be dispensed with. The Office's opinion had been that the author's advice in that matter had given them probably a very good insecticide, and they had been very sorry that the solution had had to be dropped. He would like to ask the author whether he thought its toxic influence on the workmen could be overcome, and would it be possible still to use a solution of that kind? It had been said facetiously that its mere name alone would make it a sufficient insecticide, but that might also apply to many of the other solutions which the author had described.

As to the question of using paraffin oil, he must say that he should be very hesitant about lifting a wood block floor in an important building and impregnating the blocks with paraffin oil. He should feel that that would introduce a fire risk which was dangerous and which ought not to be incurred. Further he should feel that the permanence of the treatment was very much in question, because paraffin oil volatilised within a comparatively short time. He would like to know the author's opinion as to the permanence of the effect of paraffin oil in such a case.

The theory of the use of dichlorbenzene, which H.M. Office of Works had been employing in agreement with the author of the paper, was to destroy the waxy-like covering of the larva first, and then to penetrate into each living cell of the insect and to act as a kind of dehydrating agent which would destroy the metabolic action essential to life. If that was so, he would like to know from the author whether that was a genuine description of its probable toxic effect.

With regard to the very interesting formulæ which the author had put upon the screen, although personally he had no chemical knowledge whatever, he did feel as a practical architect that he would rather hesitate to use a solution which had as much as 83 per cent. of water in it, because his experience showed him that to introduce water into an old timber structure would first of all probably set up dry rot, secondly would cause warping, and thirdly would hasten incipient decay. With regard to dry rot, in certain of the structures which he had seen he found that dry rot was almost as serious a problem as the attack of the death watch beetle, and dry rot was prevalent to such an extent that he should certainly, except under the most expert advice, refrain from using a solution with so high a percentage of water.

With regard to the many suggestions which had been thrown out as to toxic preparations which could be used to eradicate the death watch beetle, that was really the problem. Could the author state whether cellulose acetate, for example, was really going to be permanent in action? Was it really a toxic treatment against xestobium? Was it a treatment which would be only effective on the surface of the timber, or was it a treatment which had to be extended throughout the whole body of the timber by a system of boring and penetration? If a preparation, selected by specialists like the author, had to be applied throughout the whole body of the timber of the roof, it was a very big matter indeed. In the case of Westminster Hall it would have involved the penetration of 50,000 ft. cube of oak timber, and that was a problem which, as a practical man, he could hardly face.

With regard to the question of the termination of the attack of the xestobium, he could say from a wide experience that there was hardly a single mediæval structure with which he had been concerned which did not show some signs of an attack. He had thought at certain times that that attack had actually terminated before he had finished with the structure, but he had found definite evidence of the existence of live larvæ in the roof. He had even found in timbers in Westminster Hall, where the attack had been considered to be entirely over, that when those timbers had been removed and split, there were evidences of live larvæ in them. He would like to ask the author whether there was any direct evidence that structures which had been attacked by xestobium showed definitely that that attack was over and finally finished. If there was such evidence which could be trusted, then it appeared to him it would be a guide as to how conditions could be produced which would terminate the attack.

He thought the author's point about ventilation was a most important one. Indeed it had been on the author's advice that he had provided a much increased ventilation in the roofs of certain of the structures dealt with by H.M. Office of Works. He thought the point of ventilation could not be too strongly emphasised.

In conclusion, the whole matter was one which called for very close and continuous enquiry. It would be very helpful if the author could state in a brief form how the investigation had advanced and what was the position at the present day, and if he would lay down in scientific language the points of failure. The failures were not too grave to overcome. Personally he had visualised the possibility of dealing with structures in the future by again treating them with some perfect insecticide against *xestobium tessellatum*, such as he hoped the author could invent.

MR. NOEL HEATON said the author had been very generous in referring to his assistance in the paper, but he felt that the obligation was entirely the other way round. For many years past he had done a good deal of work in connection with research on building materials and he had at various times been approached to give advice on the matter dealt with by the author, but had always felt chary of expressing any opinion as to the best method of treatment for destroying this pest, because it was more an entomological than a chemical problem.

Recently, however, he had had the opportunity of discussing this matter on several occasions with Professor Lefroy, who had given him an immense amount of information. As a result of their discussions he had formulated some hypotheses as to the materials and processes to be used for exterminating the pest, and he thought that it was only by co-operation of this kind that such problems could be solved. In many respects the difficulty of the problem was on parallel lines to that of the preservation of stone. One of the great difficulties, for example, was to find a means of getting adequate penetration of the poisonous material applied to the wood in order to rout out the beetle or to kill it *in situ*. Linked up with that problem of penetration were all sorts of other difficulties which had been clearly stated by the author and which showed how extremely difficult it was to find a really efficient method of attack. One point had often occurred to him, namely, whether fumigation of the wood would be a preventative of the attack of the beetle. In mediæval days most timber roofs were subject to constant fumigation, owing to the burning of incense, and he had often wondered how far that would act as a preventative. He would like to ask the author his opinion on that point, and whether anything definite was known as to whether the ravages of the beetle dated back to mediæval times or were comparatively recent.

Before one could determine the method of attack, one wanted considerable information on the question of the toxicity of different substances to insects. It seemed to him that in the past a great mistake had been made in trying to get rid of the beetle by the use of substances which were strongly poisonous to human beings. There were poisons which were harmless to human beings but which were fatal to insects, and he thought that was a line of research which was clearly indicated. On the other hand, there were poisons which were harmless to insects but which were fatal to human beings, and in that connection he might mention that during the war he had found that chlorine gas had no effect on flies or butterflies.

He would like to ask the author whether the use of walnut oil had been tried. It was well-known that everything connected with the walnut tree seemed to be extraordinarily antipathetic to insects. He therefore imagined that walnut oil might have toxic properties to insects, and therefore might possibly be a better substance to use than cedar wood oil.

One important point in the preservation of modern buildings was the treatment of any new wood which was put in in the course of re-construction, in order to make quite certain that one did not re-introduce beetles in the place of those which had already gone out.

The question of the cessation of the attack seemed to be a very puzzling one, and he would like the author to give a little more information as to whether there was any evidence as to when the attack ceased. He would like to know, for instance, whether cases had been found where the beetle had disappeared before the destruction of the timber was complete, and there was still, so to speak, plenty of food in the larder; or whether it was simply that the beetles moved to a fresh area after having completed their work of destruction. If there were cases where the attack had begun and ceased before any serious damage had been done, clearly something must have happened to frighten the beetle away. Was there any evidence as to what that something must have been, apart from the question of increased ventilation?

MR. A. R. POWYS said there was very considerable danger in the repairing of timber buildings not suffering from the ravages of the beetle, in the use of old timbers. There was to-day a great vogue for antiques. Men who were living in ordinary modern houses often desired to make them appear old, and in order to do this bought up pieces of old buildings and fitted them into their new building. That was one way of introducing the beetle into buildings which had been up to that moment free from an attack.

MR. W. A. FORSYTH F.R.I.B.A., said he had only studied the question more or less superficially, but he had found that in roofs which were unventilated the beetle was most prolific and active. In one roof with which he had had to deal, which had been in position since the end of the 13th century, and which had nothing but ventilation and light in it, the timbers had survived to this day without any sign of any insect whatever. He would like to ask the author why he had not referred to light as one of the conditions which were unfavourable to the insect. As far as he had observed the ravages of the beetle were of recent origin, and he desired to ask if any investigation had been made as to the length of time during which the insect had been known to exist. His own view was that most of the ravages occurred in roofs. The heat of a building rose into the roof, and his own belief was that the beetle flourished to a greater extent in heat, and where there was little light or air than under any other conditions. There was one type of oak structure which did not seem to suffer intensely from the action of the death watch beetle and that was a belfry. An oak belfry seemed to stand a visitation of the insect remarkably well. That was mainly because it was subject to intense ventilation and very strong light. He sincerely hoped that the author could continue his investigations into the matter.

Mr. R. à-Ababrelton said in South Africa one could occasionally take door posts and things of that sort in one's hand and easily crush them. That arose simply from the attacks of ants. He had been wondering whether ants attacked wood also in this country. Sir Frank Baines had asked if the use of paraffin was effective. In 1906 he found on his return from South Africa two old chairs in his house which had been attacked by the beetle. He heavily dosed those chairs with paraffin. He went back again to South Africa and, after his return in 1912, had found that the insect had not been entirely eradicated from the chairs. He thereupon gave them another great dose of paraffin, and apparently the insect ceased its ravages until a few days ago, when seeing the notice of the lecture, he had thought it well to look at those chairs again. He then found indications that the paraffin had *not* been entirely effectual.

Dr. W. Rushton Parker enquired if X-rays would be of any use in diagnosing whether or not the beetle was in timber.

The Chairman (Sir Aston Webb) said he was much interested, and to some extent puzzled, in the problem under discussion. It had been asked over and over again, why did the attack suddenly cease? That was one of the things which everybody interested in the matter desired to know. He supposed it ceased because the beetle went elsewhere. The beetle itself did not do the harm, except through the fact that it laid its eggs somewhere, and he supposed that when the beetle was satisfied that there was not much more to be had in a particular building it departed and laid its eggs elsewhere. He had received an enormous amount of help from the author, and any little knowledge he had obtained about the subject he had got from Professor Lefroy, and he was very grateful to him for it.

Ventilation was, no doubt, a very important point. He had found, as others had, that places which were heated were those most attacked by the beetle. It seemed pretty clear, therefore, that ventilation was a very desirable thing to provide. Another thing he had found was that the insects seemed to attack the main timbers more than the smaller timbers. The author had showed some very interesting sections, one of which appeared to show the grubs going at right angles to the grain of the wood. He imagined that that was very unusual, as generally the grubs appeared to run with the grain of the wood. Quite recently he had had occasion to have X-rays taken of certain timber which had been affected, and in all those cases the grub was seen travelling with the grain of the wood, avoiding the hard portions which divided the various grains. Evidently, however, from the author's section the grubs did occasionally go the other way about.

He had found some difficulty in saturating timber with liquid. One could bore holes in the wood and force the liquid into the hole, but it did not follow that one could get it to go exactly where one wanted it to. He had found it very useful to bore through the wood until one came to a shake in the timber. The liquid would then follow the shake, and so one would get over a great deal of the timber which was most likely to be affected. The same applied to the joints. Liquid could be forced into the joints and into any shakes anywhere. If one took a timber and marked on it where it was most affected one would always find little marks round the joints, because the beetle got into those fine cracks, and laid its eggs in the crack, and then the grub came out. The same was the case with the shakes. The beetle got into any little opening of that form, and started on the softer wood in the shakes.

With regard to the treatment of roofs, each one of those concerned had to take the responsibility of doing what seemed to him the best in the way of stopping the decay, in whatever manner he thought best under the best advice he could get. Personally he should like to say that he thought Westminster Hall roof a very fine design. He hoped Mr. Woodward might live for 400 years and see it still there. It was the duty of architects and others to take every possible step they could to ensure, with the knowledge which they had (which even the author admitted was at present defective), the preservation of buildings for the next generation, and for as long as they possibly could, taking advantage of all the advice and expert information which they might have at their disposal.

The Author, in reply, said he did not think there was anything practical to be gained in dealing with the yeast. The point had been investigated, and if it was possible to deal with the yeast as a means of dealing with the insects it would be found out. At the present moment he was afraid it was more interesting than practical. Certainly the best poison had not yet been discovered. Dichlorbenzene was by no means the best; he thought chemical knowledge could give something better. Sir Frank Baines had asked how long the paraffin oil put on floor blocks would last. In the particular case which he had in mind the paraffin oil lasted sufficiently long for the purpose. Sir Frank Baines also objected to 83 per cent. of water in one formula which he had given, but he would like to point out that that was a surface treatment. The water was not pushed into the timber. Water treatment was possible where it was a purely surface treatment, and he only suggested it in that connection.

One point had been raised about the cycle. Could the cycle be broken; that was to say, could the insect be interfered with in its three years' course so that one generation was stopped? He thought it was a mistaken idea. Although the insects did take three years to develop, they did not all, so to speak, start in 1920. There were some which started in 1920, some in 1921, and some in 1922, so that although the whole cycle was a three-year one, by simply breaking it at one point one was not going to stop it at all. He had heard that point of the cycle discussed before, but he thought it was a very doubtful point indeed.

With regard to the cessation of an attack, everybody was very much in the dark about that. As to whether ventilation and light affected the cessation of an attack, he had seen cases where he was absolutely certain that an attack had started; there had been abundant wood, and everything had been right so far as one could see, and yet the attack had ceased. He had no knowledge as to why. It was one of the most interesting problems in connection with the matter at the present moment as to why an attack suddenly stopped. If only the factors about that could be discovered the problem could be tackled in a much better way. With regard to Mr. Noel Heaton's point about the fumigation of incense, so very little was known about the subject that he did not think anyone knew of a case of a building in which incense had been regularly used which had been affected with the ravages of the beetle. He imagined Sir Frank Baines and others might know of cases where incense was being still used, and where the building was or was not being attacked. He imagined, speaking as an entomologist, that the continued use of incense in a building would prevent attack by the beetle, but it was a point on which there was no information.

One very interesting question had been raised, namely, when did the attacks start? Were they all of the last two centuries, or did they start with the buildings themselves? He was sorry there was so little information on the subject. It was quite possible that no building had been attacked until within the last two centuries. He wished that more was known about it. It all went to show the importance of getting information and correlating it.

Ants did not occur in timber in this country. He did not think X-rays could be used to find out whether an attack was going on.

With regard to the penetration of timber with a liquid, it would be within the knowledge of Sir Frank Baines that experiments were made before Westminster Hall treatment was started with penetration of timber, and it had been shown that if the liquid was pumped into solid oak for, say, six months, it would penetrate a beam 20 ft. long right through. He did not think it was a practicable thing to soak timber with a liquid in that way.

The meeting then terminated.

OBITUARY.

Henry Somerson Freeman.—Mr. Henry S. Freeman, who died on February 22nd, at his residence at Nutfield, Surrey, at the age of 81, was elected a Member of the Royal Society of Arts in 1881. He served for five years in the Bombay Gas Company, and in 1869 was appointed engineer to the then Wandsworth Gas Company. He continued to act as engineer and consulting engineer to this company for twenty-eight years, and subsequently as a director for nearly twenty-five years. On the amalgamation of the companies in 1913 he became one of the directors of the Wandsworth, Wimbledon and Epsom District Gas Company. He was largely responsible for the policy whereby the company has built up its fine modern works, with half-a-mile frontage on the Thames, and a fleet of sea-going steamers.

Mr. Freeman was a keen sportsman and athlete. On one occasion he came in second in an all-England swimming race from Putney to Hammersmith; he won numerous cups for sculling and rowing; and he was a keen cricketer and a good rider to hounds.

MURRAY RIVER WORKS.

Some interesting particulars of the irrigation works on the Murray River were recently given by a Melbourne correspondent of the *Times Trade and Engineering Supplement.*

There will have to be great development along the River Murray, with a corresponding increase in production for which a profitable market can be found, to justify the expenditure of £10,000,000, which is the latest estimate of the cost of the conservation and irrigation works now in course of construction.

The River Murray, Australia's greatest watercourse, is bounded on each side by rich tracts of country which can be converted into productive areas by irrigation. This is being done, but the most serious problem confronting the enterprise at present is the discovery of markets to absorb the ever-increasing volume of production.

The principal work now engaging the attention of two of the constructing authorities—New South Wales and Victoria—is the Hume reservoir, the main storage basin situated half a mile below the point where the Mitta Mitta River meets the Murray. In this dam 1,100,000 acre feet of water will be impounded by an embankment 3,600ft. long. It will have a full supply level of about 73ft. in depth over the flats on the Victorian side, increased to 94ft. in the river channel. This storage will rank amongst the greatest in the world. It will be the fourth largest reservoir, those exceeding it in capacity being the Elephant Butte dam, the Assuan dam, and the Roosevelt dam.

The embankment 32ft. wide on the top with crest at 12ft. above full supply level, will extend across the alluvial flats on the Victorian side, where the granite occurs at a depth of about 34ft. below the surface. The slopes are 3 to 1 up-stream and 2½ to 1 down-stream. The embankment is being constructed with a concrete core wall carried down to the granite, the material on each side of the core wall being specially selected and consolidated. The spillway is being constructed to avoid undue submergence of adjacent lands by high floods coming down on top of a full reservoir. It will be capable of discharging 100,000 cu. ft a second, and will comprise a concrete dam 710ft. long, having movable gates. Piers carrying the roadway will rise above the concrete and will act as supports for 31 gates, each 20ft. wide and 15ft. high above the crest. In flood times these will be lowered behind the up-stream face by suitable gearing operated by turbines situated in a chamber within the dam. It is estimated by the constructing engineers that a surcharge of 15ft. over the concrete wall will be sufficient to discharge the maximum flood. For ordinary regulated flow discharge eight outlet pipes 6ft. in diameter, with suitable controlling valves, are being provided on the New South Wales bank.

A new lock and weir, No. 9, is being constructed in South Australia to divert water from the Murray into the Lake Victoria storage. This natural reservoir is designed to safeguard South Australian interests. It will be fed during the flood period through Frenchmen's and Rufus Creeks, and when completed will form a balance storage of great value for supplying the lower Murray during periods of low flow. The needle weir regulator which has served for a number of years to hold back a part of the flood waters will be superseded by a permanent structure, which will include extensive embankments with regulators to maintain the height of the water in the lake at within 2ft. of the height of the pool in the lock and weir immediately above. The lake storage will then be about 6½ miles long, with a water surface of approximately 30,000 acres, a maximum depth of 34ft., and a storage of 514,000 acre feet.

When these two large storage basins are completed the depth of the river will be maintained by a series of 35 weirs and locks, so that the full length of the stream may be open for navigation all the year round. This will mean a cheapening of transport and a consequent reduction in the cost of conveying products of the Murray settlements to the sea-board for shipment oversea. Irrigation, however, is the paramount consideration, and the work is being proceeded with towards this end.

RED OXIDE OF IRON INDUSTRY OF MALAGA.

Among the more important products exported from Malaga is red oxide of iron. It is mined to some extent in the Province of Malaga, but principally in the mountainous regions in the Province of Jaen. The crude ore is carried from the mines to Malaga, where it is levigated. In a few instances, reports the United States Vice-Consul at Malaga, it is still necessary to carry this ore some little distance on mule back to the nearest railway, but nearly all of the larger mining companies now possess overhead cables which connect the mines with the main line.

The ore milled in Malaga is reputed to be of very good quality, not equal in colour to the more expensive variety mined in the Persian Gulf region, but much higher in ferric-oxide contents and therefore of more value as a preservative for iron and woodwork. Moreover, the Persian ore is only shipped in the crude form, there being no levigating or grinding plants on the island of Ormuz or in Persia.

A small amount of crude red oxide of iron is exported from Malaga, but the demand is becoming greater every day for the levigated ore, owing to the cheapness of production in that district.

The levigating establishments, which are located in Malaga, reduce the crude ore to a fine pulverised form after having extracted all impurities. The systems of levigation vary, but the most satisfactory appears to be "water floating," which is accomplished by passing the mineral through a series of tanks so that only the very finest particles in suspension ever reach the final or "settling" tank.

The red-oxide industry has expanded considerably during the last 10 years, as is evidenced by the following figures of levigated ore exported to the United States alone:

Year.	Quantity.	Value.
	Pounds.	*Dollars.*
1913............	1,336,968	113,938
1920............	7,459,583	178,314
1921............	7,669,665	176,886
1922............	9,196,123	192,177
1923 (first 6 mths)	6,705,542	133,775

The greatest increase has occurred during the past three years. This is accounted for by the growing use of paints in construction work of all kinds. The present boom in construction, which is most notable in England and the United States, has substantially aided the red-oxide trade. The cement and rubber trades also now consume large quantities, and a large amount is used in paper staining.

Approximately 60 per cent. of the ore exported from Malaga is shipped to the United States, about 30 per cent. goes to the United Kingdom, and the remaining 10 per cent. is taken by various other countries.

THE BRISTLE INDUSTRY OF TIENTSIN.

Bristles constitute one of the leading items of export from Tientsin. According to the Chinese maritime customs returns, exportation of bristles from Tientsin in 1919 amounted to 2,287,723 pounds; in 1920 to 2,506,933 pounds; and in 1921 to 1,890,400 pounds. The returns show that the bulk of the bristles go to the United States. England, France, and Japan, however, share a portion of the trade. The annual declared-export returns for the same periods show that shipments of bristles to the United States amounted to 1,258,784 pounds, valued at $1,857,015, in 1919; 1,649,828 pounds, with a value of $3,547,599, in 1920; and 1,107,003 pounds, worth $1,535,786, in 1921.

Hotou (located at the terminus of the East Grand Canal) is a large distributing centre in North China. Here bristles are brought from Tsunhua, Yungping, regions outside the great wall, and Manchuria, and, after being sorted and graded, are sent to Tientsin by junk or railway. Paotingfu and Peking are other large bristle centres, whence shipment is made to Tientsin either by railway or, from Paotingfu, by river. It is believed that the Paotingfu article is slightly inferior in quality to the Hotou product. According to a report by the United States Consul-General at Tientsin, there are several ways for working the bristle business for export from Tientsin. The principal amount is exported in assortments of 55 or 66 cases, but other assortments containing 8, 40, 100, etc., are sometimes made to meet special demand. Of the usual assortments, the 55 is considered the most desirable because it contains a greater amount of long-length bristles. One of the usual type of 55-case assortments contains about the same number of cases of bristles of each length, from 2¼ to 5¼ inches. The bristles are packed in cases of 110 pounds net. The 66-case assortment generally sells for about half as much as the 55, which is due to the fact that it contains a very large number of cases of short lengths. Other factors that govern the price are the cleanliness of the bristle, the colour, the elasticity, and the degree of solidarity of the bundles.

THE MONGOL LEATHER BOOT INDUSTRY.

One of the most important industries in Kalgan, writes the United States Consul of that place, is the manufacture of Mongol boots. The dress of the Mongolian people is quite different from that of the Chinese people, and probably the most distinctive feature of the Mongol's dress is the curious, toe-tilted, decorated leather boot. The same style of boot is worn winter and summer by Mongol women, men, and children. It has no raised heel, but is whole-soled from tilted toe-tip to the heel. The upper is made of locally tanned leather, in tan or black, and extends to a height of 15 inches in the back, and about 16½ in the front. The upper does not fit the leg tightly, but there is sufficient room to permit the wearing of a heavy felt sock and to stuff the lower part of the Mongol's baggy trousers into the boots. The upper is soft and pliable, and is lined with coarse, thin, blue cotton cloth, resembling cheesecloth. The sole is about one-half inch thick, made up of leather and felt.

After the boot is put together, the sole is covered with a native wood oil which coagulates in drying and looks like glue, and renders the sole waterproof. On the completed boot are sewn conventional decorations in leather stripes. The amount of decoration on a boot is an important factor in the cost. The tip is tilted by a wooden last. The work on a boot is done wholly by hand. After all the materials are cut, the different parts are sewn together by hand; a worker can sew one pair of boots in two days. Prices range from about 14/- to 42/-, depending on the quality of the leather used and the amount of decoration. A pair of boots of a medium quality, with a minimum amount of decoration, sells locally for 15s. 6d.

The industry, with an average annual production of 150,000 pairs of leather boots, valued at approximately £100,000, would appear to be large enough for modernisation. A market for boot making plant could be established only if the advantages of modern machinery could be demonstrated to the local manufacturers, who are very conservative, by the actual establishment of a small plant, where workers could be trained in the use of machinery.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 12.—**ALAN A. CAMPBELL SWINTON**, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men." (Illustrated by Photographs.) **SIR DUGALD CLERK**, K.B.E., D.Sc., F.R.S., will preside.

MARCH 19.—**R. L. ROBINSON**, Forestry Commissioner, "The Forests and Timber Supply of North America." **LORD CLINTON** will preside.

MARCH 26.—**NEAL GREEN**, "The Fishing Industry and its By-Products." **PROFESSOR E. W. MACBRIDE**, D.Sc., F.R.S., will preside.

APRIL 2.—**SIR LYNDEN MACASSEY**, K.B.E., "London Traffic."

APRIL 9.—**FRANK HOPE-JONES**, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." **PROFESSOR C. VERNON BOYS**, F.R.S., will preside.

APRIL 30.—**BRIGADIER-GENERAL SIR HENRY MAYBURY**, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "Roads."

May 5 (Monday).—T. Thorne Baker, "Photography in Industry, Science and Medicine."

May 7.—J. Robinson, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation."

May 14.—

May 21.—Professor C. Vernon Boys, F.R.S., "Calorimetry." (Trueman Wood Lecture.)

May 28.—Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Indian Section.

Friday afternoons at 4.30 o'clock:—

March 21.—Otto Rothfeld, I.C.S., "Progress of Co-operative Banking in India."

May 2.—Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced:—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

Dominions and Colonies Section.

Monday or Tuesday afternoons at 4.30 o'clock:—

May 27.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

June 16.—C. V. Corless, M.Sc., LL.D., "The Mineral Resources of Canada: The Pre-Cambrian Area."

Cantor Lectures.

Edward Victor Evans, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "A Study of the Destructive Distillation of Coal." Three Lectures. February 25; March 3, 10.

Syllabus.

Lecture III.—March 10.—The trend of developments in carbonising processes. The de-ashing of coal and other factors tending to increase the value of the therm in the form of coke.

Cobb Lectures.

Monday evenings, at 8 o'clock:—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, March 10 .. Geographical Society, 135, New Bond Street, W., 8.30 p.m. Mr. C. E. N. Bromehead, "Natural Resources in Relation to the Arts."

Metals, Institute of (Scottish Section), 39, Elmbank Crescent, Glasgow, 7.30 p.m. Annual General Meeting. Address by Mr. G. B. Brook.

Surveyors' Institution, 12, Great George Street, S.W., 8 p.m.

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. "The Johannine Authorship of the Fourth Gospel."

Brewing, Institute of (London Section), at the Engineers' Club, 39, Coventry Street, W., 7.30 p.m. Mr. V. B. Butt, "The Management of a Brewery Motor Transport."

Architectural Association, 34, Bedford Square, W.C., 8 p.m. Mr. H. S. G. Rendel, "The Gothic Revival."

Electrical Engineers, Institution of, Victoria Embankment, W.C., 7 p.m. (Informal Meeting). Mr. J. T. Laspière, "On the Work of the International Conference on E.H.T. Lines, held in Paris, November, 1923."

University of London, at King's College, Strand, W.C., 5.30 p.m. Rev. C. F. Rogers, "Ecclesiastical Music." (Lecture V.)

5.30 p.m. Dr. R. W. Seton-Watson, "A Survey of Bohemian History." (Lecture VI.)

Tuesday, March 11 .. Petroleum Technologists, Institution of, at the Royal Society of Arts, John Street, Adelphi, W.C., 5.30 p.m. Annual General Meeting. Address by President.

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. R. W. Chambers, "Civilisation and Literature of the Anglo-Saxon Period." (Lecture I.)

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Prof. W. Lochhead, "The Influence of Agricultural Colleges in the Development of Agriculture in Canada."

Transport, Institute of (Graduate Section), at the Institution of Electrical Engineers, Victoria Embankment, W.C., 6 p.m.

Asiatic Society, 74, Grosvenor Street, W., 4.30 p.m. Rev. E. N. B. Burrowes, "The Mythology of the Rivers of Babylonia."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Capt. P. T. Brown, "A Note on the Air Supply to the Larger Type of the Motor Vessel."

Mechanical Engineers, Institution of (South Wales Branch), Chamber of Commerce, Swansea, 6 p.m. Dr. C. H. Lander, "Coal and Oil."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Annual General Meeting.

University of London, University College, Gower Street, W.C., 5.30 p.m. Prof. J. W. Van Wijhe, "The Origin of the Vertebrate Skeleton." (Lecture I.)

At King's College, Strand, W.C., 5.30 p.m. Sir Bernard Pares, "Russia before Peter the Great to 1861." (Lecture VIII.)

Wednesday, March 12 .. London County Council, at the Royal Society of Arts, John Street, Adelphi, W.C., 6 p.m. Sir Napier Shaw, "Meteorology." (Lecture III.)

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m. Prof. F. S. Boas, "The Byron Centenary: 'The Satires.'"

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. W. W. Paine, "A Capital Levy."

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., 10 a.m. Annual General Meeting. 1. Address by President. 2. Paper, Mr. D. Bunting, "The Brittle Ranges in Brass, as shown by the Izod Impact Test." 3. Paper, Messrs. J. Friend and R. H. Vallance, "Determination of the Thermal Coefficients of Expansion of Some Commercial Metals and Alloys."

2.30 p.m. 1. Mr. W. E. W. Millington, and Professor F. C. Thompson, "The Investigation of a Fatigue Failure of Brass Tubes in a Feed Water Heater—with a consideration of the Nature of Fatigue." 2. Mr. Martin, "The Tensile Properties of Aluminium at High Temperatures." 3. Mr. W. E. Atkins, "The Relation between the Tensile Strength and the Electrical Resistivity of Commercially Pure Copper." 4. Mr. H. J. Wilson, "Note on the Effect of Cold-drawing and Annealing on some Electro-chemical Properties of a Low-tin Bronze."

British Decorators, Institute of, Rochdale, 7.30 p.m. Mr. T. Peters, "A Visit to Italy by a Decorator who does some Landscape Painting, illustrated by some sketches done there."

Civil Engineers, Institution of, Great George Street, S.W., 7 p.m. (Informal Meeting). 1, Mr. C. E. Stromeyer, "CO2 Recorders." 2, Mr. R. H Parsons, "The Practical Testing of Steam Boilers."

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. S. Hodgson, "Some Aspects of Book Distribution."

6 p.m. Prof. K. Pearson, "The Current Work of the Biometric and Eugenics Laboratories." (Lecture V.)

6 p.m. Mr. E. S. Pearson, "Birth Intervals as a Factor in the size of the Family."

At King's College, Strand, W.C. 5.30 p.m. Mr. W. R. Lethaby, "Craftsmen and Craftsmanship in Mediæval Westminster."

5.30 p.m. Prof. H. Driesch, "The Possibility of Metaphysics." (Lecture I.)

Thursday, March 13 .. Pottery and Glass Trades Benevolent Institution, at the Royal Society of Arts, John Street, Adelphi, W.C., 7.45 p.m. Mr. L. King, "Decoration of Glass Ware."

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 10 a.m. Annual Meeting continued. 1. Dr. J. Newton Friend, and J. S. Tidmus, "The Relative Corrosion of Zinc and Lead in Solutions of Inorganic Salts." 2. Messrs. E. R. Jette, G. E. Phragmén, and A. F. Westgren, "X-Ray Studies on the Copper-Aluminium Alloys." 3. Mr. F. W. Rowe, "The Effect of Casting Temperature on the Physical Properties of a Sand-Cast Zinc Bronze." 4. Mr. K. Iokibe, "Copper Zinc Alloys which Expand on Solidification."

2.30 p.m. Messrs. C. H. M. Jenkins and D. Hanson, "The Constitution of the Alloys of Copper and Cadmium." 2. Mr. D. Stockdale, "The Aluminium-Copper Alloys. Alloys of Intermediate Composition." 3. Dr. M. Cook, "The Cadmium-Lead-Zinc, System." 4. M. Ishiara, "The Equilibrium Diagram of the Copper-Tin System."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Historical Society, 22, Russell Square, W.C., 5 p.m. Miss A. E. Levett, "The St. Alban's Abbey Courts and Court Rolls."

London County Council, Kingsland Road, E., 7.30 p.m. Mr. P. A. Wells, "Furniture — the Kitchen and Domestic Arrangements."

Mechanical Engineers, Institution of, Graduates (North Western Section), at the Engineers' Club, Albert Square, Manchester, 7.15 p.m.. Mr. E. Cockshutt, "Engineering Contracts."

Royal Institution, Albemarle Street, W., 5.15 p.m. Dr. J. S. Flett, "Types of Volcanic Structures." (Lecture II.)

University of London, University College, Gower Street, W.C., 5.30 p.m. Sir Frederick Pollock, "Learning the Law." 5.30 p.m. Prof. J. W. Van Wijhe, "The Origin of the Vertebrate Skeleton." (Lecture II.) 3 p.m. Signor C. Pellizzi, "Galileo Galilei."

At King's College, Strand, W.C., 5.30 p.m. Dr. A. R. Pastor, "Spanish Mysticism." (Lecture III.)

5.30 p.m. Prince D. S. Mirsky "The History of Russian Literature." (Lecture VIII.)

5.30 p.m. Mr. J. W. Headlam-Morley, "The History of the word State; its Various Meanings."

At St. Mary's Hospital Medical School, Praed Street, W., 5 p.m. Prof. B. J. Collingwood, "Blood." (Lecture IV.)

At St. Thomas's Hospital, Albert Embankment, S.E., 5 p.m. Dr. J. A. Murray, "Cancer. (Lecture IV.)

Friday, March 14. .. London Society, at the Royal Society of Arts, John Street, Adelphi, W.C., 5 p.m. Mr. E. B. Chancellor, "Royal Residences in London — Past and Present."

Royal Institution, Albemarle Street, W., 9 p.m. Dr. J. W. Mackail, "The Pilgrim's Progress."

Mechanical Engineers, Institution of (Midland Branch), The University, Birmingham, 7.30 p.m. Lieut.-Col. E. K. Clark, "Literature and Engineering." (Graduates Annual Lecture).

(North Western Section) in the Memorial Hall, Manchester, 7 p.m. Mr. O. Smalley, "Modern Foundry Practice."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Lantern Lecture.

Astronomical Society, Burlington House, Piccadilly, W., 5 p.m.

Malacological Society, at the Linnean Society, Burlington House, Piccadilly, W.

Physical Society, at the Imperial College of Science, South Kensington, S.W., 5 p.m.

University of London at King's College, Strand, W.C., 5.30 p.m. Prof. R. W. Seton-Watson, "The Rise of Nationality in the Balkans." (Lecture VIII.)

5.30 p.m. Prof. H. Driesch, "The Possibility of Metaphysics." (Lecture II.)

At Bedford College for Women, 5.15 p.m., Dr. C. S. Myers, "The Future of Psychology."

Saturday, March 15 .. King Edward VII. Hospital Fund, at the Royal Society of Arts, John Street, Adelphi, W.C., 5 p.m. Mr. Allen S. Walker, "Old London and How to See it."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. Sir E. Rutherford, "Properties of Gases in Vacua." (Lecture II.)

London County Council, at the Horniman Museum, Forest Hill, S.E., 3.30 p.m. Mr. C. N. Bromehead, "Links between Geology and Art."

Metals, Institute of (Local Section), University College, Swansea, 7.15 p.m. General Discussion.

Journal of the Royal Society of Arts.

No. 3,721. VOL. LXXII.

FRIDAY, MARCH 14, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

28 APL 1924

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 19th, at 8 p.m. (Ordinary Meeting.) R. L. ROBINSON, Forestry Commissioner, "The Forests and Timber Supply of North America." LORD CLINTON, Forestry Commissioner, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

THIRTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 5th, 1924; LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

The following candidates were proposed for election as Fellows of the Society :—

Arnold, James Ernest, F.R.G.S., London.
Bethell, Lieut.-Colonel L. A. B., Landi Kotal, N.-W.F. Province, India.
Bhatia, G. R., Dehra Dun, India.
Hall, A. G., Assoc.M.Inst.C.E., Landi Kotal, N.-W.F. Province, India.
Raley, Captain George Giles Emsley, B.A., M.C., Toronto, Canada.
Roberts, Lieut.-Colonel Sir James Reid, C.I.E., F.R.C.S., London.

The following candidate was duly elected a Fellow of the Society :—

Bone, Stephen, London.

A paper on "Building and Decoration of the War Cemeteries" was read by MAJOR-GENERAL SIR FABIAN WARE, K.C.V.O., K.B.E., C.M.G., C.B.

The paper and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURE.

MONDAY EVENING, MARCH 10th, 1924, PROFESSOR HENRY E. ARMSTRONG, F.R.S., in the Chair. MR. EDWARD VICTOR EVANS, O.B.E., F.I.C., delivered the third and final lecture of his course, "A Study of the Destructive Distillation of Coal."

On the motion of the CHAIRMAN, a vote of thanks was accorded to MR. EVANS for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1924 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 22nd, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce."

The list of those who have received the medal since its institution in 1864 was printed in the last number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

ELEVENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 20TH, 1924.

SIR STANLEY BOIS in the Chair.

THE CHAIRMAN said that Mr. Burgess was a gentleman who had gone out originally to the Straits as Government Analyst, but soon after the rubber planting industry started there he had left the Government service and had gone in for planting. Therefore the audience had in Mr. Burgess that somewhat unusual combination of the scientific and the practical. It was a pleasure to think that Mr. Burgess had brought his research work to bear on so many problems connected with the rubber industry, and, as Chairman of the Rubber Growers' Association, was now doing so much to forward its interests. The subject of the paper was of exceeding interest to the rubber industry at the moment, because that industry looked to new uses and to extended uses of rubber to absorb the large amounts which now represented the potential production of the plantations in the East. Personally, as Chairman of the Propaganda Department of the Rubber Growers' Association, everything which would tend to increase those uses and to find new uses for rubber was naturally of the deepest interest to him.

The paper read was :—

NEW USES FOR RUBBER.

By P. J. Burgess, M.A., F.C.S.

(Chairman, Rubber Growers' Association.)

There is a cheerful proverb which says, "Sweet are the uses of adversity," though few of those who have so recently been passing through the hard and perilous times of adversity in rubber production will subscribe to this optimistic view.

One use of adversity has, however, been clearly seen in the development of many new uses for rubber, extension of existing uses, and an extraordinary development of the technique of rubber manufacture.

As recently as five years ago, all rubber went into public use and consumption through the orthodox and well-known channels of vulcanisation by either the hot or cold cure of dry raw rubber.

During the last five years the use of rubber milk or latex without preliminary coagulation has been applied to paper-making and to fibre impregnation; the direct vulcanisation of such latex and its subsequent coagulation into a fully vulcanised product have been developed. We have seen the direct use of coagulated dry but unvulcanised raw rubber, the use of gels of raw rubber dispersed in rubber solvents for direct moulding of rubber goods, of novel forms of gas curing and gas expended rubber and many fresh uses to which these, as well as rubber cured by orthodox methods, have been put.

It will be my pleasant duty to-night to give some account of these developments, and I have the privilege of being able to put in front of you examples which I feel sure will be of great interest to all.

The Direct Use of Latex.

Let us begin with the use of rubber milk or latex. This, as it comes from the tree, is a white mobile watery liquid, containing about 30 per cent. of raw rubber in fine suspension. The reaction of latex is faintly alkaline but on acidification, either by addition of acids or through natural changes which occur on standing for some hours, the rubber particles coalesce and coagulate into a firm mass. By the addition of substances which prevent acidification, such as 1 per cent. to 2 per cent. of ammonia, the latex can be preserved in the liquid condition, and very considerable quantities of preserved latex have been imported into this country and into the U.S.A.

In this country the chief direct use to which raw latex has been put has been by Mr. Kaye in paper-making, under the Kaye patents and process.

It is claimed that the addition of latex to the paper pulp sufficient to give one or two per cent. of raw rubber in the finished product is a direct advantage in that the rate of hydration of the cellulose fibre is accelerated and that time and power used in manufacture are therefore saved, and also that the finished product is improved, both as regards its tensile strength, its flexibility, and with larger percentages of rubber, its impermeability to water.

I have samples of papers on the table for inspection, but without accurate testing they will convey little to you I fear, as the rubber they contain is not apparent to the eye or hand, and their quality and appearance differ little from that of ordinary paper in use.

An extension of the principle to the manufacture of millboards and artificial leathers has lately been made and I have a range of these products here to-night.

It is claimed that the increased percentage of rubber to which some degree of vulcanisation has been conferred by the use of a soluble sulphide together with latex in the beater tank produces at a greatly reduced cost finished products of considerable value and enhanced strength.

Certainly, uses for the articles of which you see samples here can readily be conceived, as decorative panels, imitation leathers, etc., and in that direction some considerable consumption of rubber may eventuate, though it must be borne in mind that it is not so much the use of rubber in this direction that is novel as the manner of its introduction in the form of liquid latex.

One inventor who has in recent years devoted considerable time and attention to the direct use of raw rubber and rubber latex is Mr. Morland Dessau, and I am able through his courtesy, to show you a number of photographs of recent novelties for the invention of which he is responsible. I can scarcely hope that appreciable inroads into the total tonnage of rubber production will be made by these devices, but they show what a suitable medium rubber is for giving human ingenuity full play.

In the U.S.A. preserved latex is being used for the direct impregnation of cotton fabric by rubber for use in tyre making. Fine cotton cords, side by side, to the number of 70 or 80, forming the woof of a fabric are run through a bath of preserved latex and on drying are proved to be fully impregnated with rubber, and also to be sufficiently gummed together to obviate the necessity for weft.

It is claimed that better and more complete impregnation of the cotton fibre can be produced in this way and that the absence of weft threads gives longer life to the fabric when used in motor tyre covers and also that such fabric renders the flat drum method of tyre carcass building satisfactory and economical. The introduction of this method is due to Hopkinson, of the United States Rubber Company, who is also responsible for the method of preparation of crude dry rubber by the spraying process, a method which holds out promise of providing a more easy preparation of a considerable range of moulded rubber goods, owing to the facility with which compounding ingredients may be more intimately mixed with the latex and precipitated with the rubber in the snow or dried spray.

The use of latex in the vulcanised condition prepared according to Schidrowitz's patents, I propose to deal with later on under the head of vulcanised rubber.

A further use of latex in either the vulcanised or unvulcanised condition in the ordinary household, holds out some hope and prospect of development, as providing an easy and effective means of applying a thick coat of adhesive rubber to fabrics. Bearing in mind the high percentage of rubber contents of such latex, viz., 25 to 30 per cent., as against the 5 per cent. of rubber in ordinary rubber solution, and the fact that the latex contains neither inflammable nor poisonous volatile organic solvents, the advent of the domestic "glue pot" of liquid latex may be confidently expected in the future.

A continental technologist, Dr. Rudolph Dittmar, of Gratz, has specially interested himself in the direct utilisation of rubber latex and promises the publication of a volume dealing with this subject in the near future.

One feature of his work which appears to be novel in character is the conversion of the usual compounding ingredients, such as resin, zinc oxide, sulphur, etc., into the colloidal condition in a Plauson colloid mill, and then mixing them in water suspension with rubber latex.

Such compound latices he claims to be of special use as proofing materials, and suggests the use of it as a preservative for any masonry which is porous in texture such as sandstones, plasters and concretes.

An extension of this idea to the impregnation of wood with compound latex in order to make it water and weather proof appears to offer points of novelty—the wood being first dried at 100°-103°C., and while still warm soaked in latex for 20 minutes and then dried.

He suggests that possibly some of the old Italian violin makers may have prepared the best of their wood by impregnating it with the latex of *Ficus*, and the microscopic detection of an elastic filling substance beneath the varnish of some old violins points to this hypothesis not being so far fetched as would at first sight appear. It will be passing strange if the subtle tones of a Stradivarius or Amato masterpiece are eventually traced to and laid to the credit of this wonderful colloid rubber.

Dittmar also makes the suggestion that tea chests in Ceylon be waterproofed with rubber latex and so dispense with lead foil. This use is one that might with advantage be experimented with by Ceylon planters who have both these products available.

USE OF CREPE RUBBER FOR SHOE AND BOOT SOLES.

Raw rubber as it leaves the plantations in the East is almost exclusively in the form of either smoked sheet or crepe. I have samples of both these here and it is easy to see why the term crepe has been applied. The rough irregular surface clearly suggests the surface texture of crepe.

It has been found that the finest qualities of this crepe rubber possess extraordinary qualities as a soleing material for boots and shoes, being resilient and exceptionally durable. These two qualities combined with lightness, flexibility, silence and being waterproof, have rapidly brought crepe rubber soles into popularity, and although their introduction into this country only dates from the winter of 1921, their success has been so marked that it is estimated some 2,000 tons of crepe rubber have been absorbed during 1923 for this purpose. Testimony from all sides has been unanimous in proclaiming the suitability of the crepe rubber sole for sporting purposes, golf, tennis, bowls, racquets and all games where grip on the ground and footwork are required, while for general use, such soles are practically everlasting, and certainly in durability and wear will outlast the uppers to which they are attached. The public has not been slow to appreciate these sale points, nor have the manufacturers or traders been behindhand in meeting the demand, which has also been stimulated by organised propaganda work by the Rubber Growers' Association in bringing these high service qualities clearly before the public. While up to the present time the chief demand has been for sports' shoes, the same qualities which make crepe rubber so suitable for sport also make it suitable for work, and I look forward to see this soleing material as the standard equipment for all boots and shoes and the practical elimination of the repairs bill for boots and shoes from the domestic budget. There has been found in natural plantation finished crepe rubber a material which will defeat that most destructive of all creatures in its most determined attempt at destruction—I refer to the British boy, and I picture his sadness of heart when he finds he cannot in a few weeks kick out his boots when shod with crepe rubber, to say nothing of being unable to slide on the pavement and strike sparks from metal heels. In order to obtain satisfactory results it is desirable that the crepe rubber be plantation finished. This phrase means that the only milling or heavy rolling process to which the crepe be subjected shall be that given it when freshly coagulated. If the rubber be dry and matured as when it reaches this country, further rolling and working thin sheets together to form soleing crepe tends to destroy the nerve and gristle of the raw rubber and such re-worked material is never entirely satisfactory as a soleing material. It appears probable that the reticulated network of proteid material formed during coagulation of the latex plays an important part in giving the tough gristly character to virgin crepe, and when this is once destroyed by re-rolling and mastication, the resulting product is soft, liable to spread in use, and altogether wanting in nerve. It is not always easy to tell by inspection whether specimens of rubber are plantation finished or rerolled products, but the best simple test is to cut a thin strip, and warm it and then to pull and stretch it. Genuine plantation finished crepe sole rubber will retain its elasticity, but the built up imitation will usually pull to pieces disclosing lamination, or show very inferior elastic recovery.

In the application of crepe rubber as a soleing material, the one great practical trouble has been in obtaining firm and permanent adhesion between the rubber and leather of the boot. The technical difficulties have, however, been largely overcome and in expert hands simple sticking of the leather and rubber together by a rubber adhesive has proved effective, but in the majority of cases the better and safer practice is to fix on the sole in two layers—the first thin layer next the leather sole being both solutioned and sewn to the leather. On to this thin layer of rubber the second thicker rubber sole can easily and permanently be stuck with any rubber solution.

In order to extend and popularise the use of crepe rubber soles for general wear, two things in my opinion are necessary :—

1. The retail price of such footwear must be reduced until it is equal to, or less than that of leather soled boots.

2. The fixing of the sole must be made more simple for the retail trade and artisan.

I should like to see put on the retail market supplies of suitable crepe of ⅛ inch thickness, stuck satisfactorily to a thin leather or tough artificial leather backing, capable of being in turn stuck and nailed with shoemaker's brads to any leather sole, new or old, by country cobbler or handy man.

There should also be on sale in retail shops and at reasonable prices supplies of raw crepe rubber suitable for soleing of ⅛ inch thickness, and more without such backing which can be used for building up a thicker sole when the basal portion has been fixed to the boot. Raw rubber can be easily and permanently stuck to raw rubber by any kind of rubber solution or even at a pinch by the plain use of benzene or any rubber solvent, and there is no difficulty whatever for anyone in adding extra clean raw rubber to a raw rubber surface. Facilities must be provided in this way for popularising, by direct appeal to the pockets of the masses, a form of footwear which will give service at a minimum of cost, and those interested in the absorption of raw rubber must see that the talking point of cheapness and service is not obscured and rendered null and void by excessive middleman profits, such as at present stand between the sale of raw rubber at 1/6 per pound wholesale and 10/6 per pound retail.

There are many further technical points in connexion with this new use for rubber that I have not time to go into fully now, but I can recommend to your attention a little handbook prepared by the Rubber Growers' Association which gives a full account of the crepe rubber sole, and the technical points in connexion with its application.

I should like, however, to hold your attention for a few minutes to some general considerations arising from the use of crepe rubber for soleing.

Each pair of shoes soled and heeled with crepe rubber may be taken as absorbing one pound of pure raw rubber. For men's boots the figure is rather more but on the average one pound is a near approximation.

From my own experience with these soles I do not estimate that the average user will wear away one pound of rubber from his boot in a year's use, but allowing for casual loss, there will not be much error in assuming that one pound of rubber will be destroyed annually for each user of crepe rubber soles, when such soles are used for all purposes, and not merely for sports shoes.

On this basis each 1,000 tons of rubber used will mean the daily use of crepe rubber soles by 2¼ million people. It is estimated that 2,000 tons have already gone into consumption for this purpose through the usual trade channels in this country and assuming that 1,000 tons have been exported the remaining 1,000 tons here, are sufficient to equip 2,240,000 pairs of boots. Simple observation of the soles of the British Public shows that nothing approaching 2¼ million people, or one in every twelve, in this country are daily using crepe rubber soles; it is, therefore, clear that the bulk of this 1,000 tons must represent "original equipment" and that the annual replacement demand has not yet begun to be felt.

While recognising the magnitude and possibility of this new use, we must also recognise the limitations, and we are still far from tearing leather from the soles of the public's boots and putting rubber in its place.

Here too, it is only fair to consider some of the objections raised to the crepe sole, the chief of which are the liability to slip on wet, greasy pavements, and some tendency to heating of the feet on account of the waterproof nature of the material. The latter objection is more imaginary than real, and is largely prejudice based on experience with rubber overshoes, where not only the soles but the uppers as well are waterproof. Any tendency in this direction can, however, be easily met by the use of a loofah sock in the shoe. The difficulty of obtaining secure foothold on greasy pavements is a very real one, and becomes very acute when the initial roughness of the soles is worn away. Soles with recessed cavities have been recommended, but I have personally not found such recessing efficient. A satisfactory cure appears to be by renewing the ribbing of the rubber surface by cutting furrows across the soles with a sharp table knife, wetted with soap and water for easy cutting, removing the V sectioned strips of rubber and thus reforming a strongly ribbed pattern again upon the sole.

Suggestions for some inlay of leather, either in the form of studs or bars have been made, but such expedients have not become popular. In my opinion this liability to slip under wet weather town conditions is the one real objection to the use of the raw rubber sole, and this point must be met before their use can become universal. Details of colour and finish can, I think, be safely left to the practical boot manufacturer to overcome, but it is a matter for those who are largely interested in the raw rubber position to see that some cure for slipping in mud is satisfactorily developed.

It has been said that the crepe rubber sole is a "fad" and that it will not take permanent hold on the public taste. It is sad work posing as a prophet, and the only certain thing is the certainty of uncertainty. But without fear of contradiction, I am prepared to assert that the crepe rubber sole is far superior to any other form of sole yet put on the market on the counts of extreme durability, silence, lightness, flexibility and being water-tight. I cannot say that something better will never be made, but I am sure of this—that if the better thing be made of vulcanised rubber it will have to be a very high grade mixing and contain a high percentage of rubber. The crepe rubber sole has established a standard and the public after experience with it will never again tolerate shoddy rubber composition soles which wear out in a couple of weeks and are dear at the cheapest of cut prices.

The indestructibility of the crepe sole will also have the effect of creating a large stock of crude rubber scattered in the hands, or better on the feet, of the general public, a rubber which will eventually come into the scrap market and be available without going through the reclaiming process. A similar consideration applies to all other uses of raw rubber by the general public, and the recent development in the manufacture of raw rubber mats, inlaid in various patterns and containing practically 100 per cent. pure rubber, samples of which I have here on the table, will work in the same direction because the mats will certainly never wear away in the lifetime of the user. It may well happen that such mats in time of rubber scarcity and high prices will be worth more as scrap than they are now new.

A number of other uses for raw rubber have been suggested and to some extent developed during the last year or two, as handles for golf clubs, racquets, bats, etc., but the use in these directions is very limited owing to liability of the rubber to harden and soften with cold and heat and to become tacky under the influence of sunlight. For all such purposes rubber vulcanised in some way or other is, I think, preferable, and attempts to develop the use of unvulcanised rubber in these directions are in the long run not likely to succeed.

VULCANISED RUBBER.

Most prominent among the new and, indeed, revolutionary new processes is that due to Dr. Schidrowitz, in which rubber in the latex itself is converted into a vulcanised product, by the addition of sulphur or sulphur yielding substances, accelerators and fillings as required and then heated, the latex meanwhile being kept in the originally liquid state by ammonia, and other means.

While unchanged so far as its liquidity and capacity for coagulation on acidification are concerned the latex after such treatment consists of a suspension of vulcanised rubber particles, while the coagulum from such vulcanised latex is found to present all the features of fully vulcanised rubber. It is not easy to see the limit to the uses to which such vulcanised latex may be put, provided suitable machinery and technical equipment are devised for the new problems in manufacture which this new material presents. It will be interesting to consider some of the directions in which vulcanised latex has already been applied and the particular advantages associated with it.

TYRES. It is claimed that factory procedure is much simplified by the ease of control of vulcanisation of the tyre carcass owing to the elimination of the difficulties of variability of ordinary raw rubber, and the simplification of the control of the sulphur. In connexion with processes connected with tyre building, impregnation of cotton with rubber by the use of vulcanised latex is considered to be simplified and improved, whether such impregnation takes place with the cotton wool, with a fine count cotton to be subsequently cabled, with cabled cord or with cord fabric.

One most important claim, which if substantiated, must have far reaching results, is that the final product of latex impregnated cord is 20 to 30 per cent. stronger than cord rubber proofed in the ordinary way. This improvement in strength would allow a cheaper grade of cotton fibre to be employed, and would go far towards solving the problem of a shortage in the world's supply of first quality cotton. A new and improved method of manufacture of waterproof string, cord and ropes for all general uses, both old and new, is similarly opened up. Proofing fabrics by liquid vulcanised latex is claimed to be cheaper, and to give new effects, and to be capable of use when ordinary rubber proofing methods cannot satisfactorily be applied and in this sense the process of Dr. Schidrowitz may be regarded as a new use of rubber.

In this way too, rubber can come into direct competition with oil for fabric proofing, the process being superior in points of speed, being continuous in action, giving a product free from smell, less tearable, with no tendency to deteriorate in the manner characteristic of oiled products, a much longer life and capable of being easily repaired. Claims are made that for use in paper making vulcanised latex is as well adapted as raw latex, and also that the finished product is better. There would appear to be some new uses for vulcanised latex in connection with building operations in the form of distempers, roof compounds, brick waterproofing, with cements and floorings.

As an adhesive for joining wood, leather or fabric to rubber its use may be very extensive, and in this connexion there is an interesting new use for vulcanised latex in bill-posting. This medium by rendering the paper fabric of the advertisement waterproof and being itself a waterproof adhesive gives long life to the poster and any extra cost of vulcanised latex over bill posters' paste is repaid by the durability of the work. Results have shown that posters fixed in this way are good for at least six months' display, in any type of our winter weather.

For rubber sheet of all kinds for solid and dipped rubber goods it is claimed that vulcanised latex is fully adapted and gives products which are odourless, and have longer life and ageing qualities, and in general are much less liable to failure from errors in curing owing to the greater ease of control of the free sulphur and practical elimination of all free and uncombined sulphur from the finished products.

Through the courtesy of the Vultex Products Ltd., I am able to show you a large range of products made from vulcanised liquid latex.

With rubber compounded and cured by old and well known methods there are every week new uses being suggested and developed.

It is only necessary to turn over the pages of the rubber trade journals or to study the rubber patents files to appreciate the mass of new development of rubber use which is day by day permeating the whole industrial world. One of the most recent developments and one which promises, I consider, to be a big consumer of raw rubber in the future is in the better springing of road vehicles by the elimination of the metal shackles and bolts which support and control the ends of the usual leaf spring and replacing them by rubber shock insulators. In this new method of construction the ends of the springs are imbedded in rubber blocks which are held under compression in metal casings rigidly attached to the frame of the vehicle. In this way a second line of rubber defence between road shock and the vehicle is provided, and not only is obtained additional comfort in riding, but noise and rattle from loose shackle pins and metal to metal contacts are eliminated.

It will be noted that there is no movement nor friction between surfaces, but the rubber provides an elastic bed for the movements of the spring ends. These shock insulators do away with shackles, bolts, nuts, bushed and hardened surfaces, machinery and fitting, and, what would appeal strongly to the owner driver of a car, eliminate once and for all grease caps and oil from spring ends. In the U.S.A. these shock insulators are in use on light motor cars as well as on heavy buses. The new Mack bus, weighing 9,480 pounds or rather over 4 tons, is equipped with these shock insulators at the ends of all springs, and the builders of the 5 ton Mack lorry give testimony that at the end of 50,000 miles of running, no wear can be shown in the rubber blocks. Looking at this development from the point of view of the consumption of raw rubber, the amount of rubber in a set of these shock absorbers may be taken as the equivalent to the rubber in a single tyre. While this would imply for original equipment a consumption of rubber which would run into approximately 4,000 tons for 1,000,000 passenger motors, if the claim of longer life to tyres in consequence of shock reduction be substantiated, the total consumption of rubber might, in the long run, be actually reduced.

Another and totally different recent development is in connexion with crushing and grinding mills, in which the material to be ground is enclosed in a revolving tubular vessel with a number of heavy iron balls. Until recently the linings of these tubular vessels or tube mills, were of thick iron or steel plate. It has been found that this iron plate can be advantageously replaced by a rubber lining which not only resists the wear and tear of the rocks and iron balls better than did the metal lining, but it is also found that grinding takes place more rapidly and more perfectly. This curious and unexpected result is probably due to the rubber walls of the mill as it revolves gripping the heavy iron balls better than the metal lining, lifting them higher without slipping and eventually letting them fall with greater effect upon each other and the material to be pulverised.

There has just been sent to Canada, for use in a tube mill, the first liner built up of crude crepe rubber instead of vulcanised rubber. The liner measured ten by four feet, and was one inch thick, weighing 205 lbs.

ROAD SURFACES AND PAVING. For many years efforts have been made to use rubber compounded and vulcanised as the surface material for roads and pavements, and recently the very low price of raw rubber has stimulated efforts to find extended use of the material in this direction. The advantages of its use are fourfold—absence of vibration, silence, durability and non-skidding. The difficulty now appears to be to find a really satisfactory method of application. Road surveyors favour blocks of about 9″ × 4½″ × 3″, of which the upper wearing surface is a high quality compound. This size is thought to be most suitable for laying, taking up, patching, etc. The trouble in the past had been to obtain a satisfactory adhesion of the rubber layer to the base of the block, though this appears to be now solved by the blocks used by Rubber Roadways in the Borough High Street, Southwark, a small strip in Holborn and in the latest area round the Cenotaph in Whitehall. The "Cresson" block manufactured in Singapore is also reported to be efficient in this direction. The adhesion of the soft resilient rubber surface to the rigid hard base of the block is in both cases effected by direct vulcanisation and is rendered possible by the base of the block containing a certain proportion of rubber.

The most suitable shape, size, and form of block for laying so as to prevent creeping, lifting and loosening of the blocks with traffic and making the jointing watertight is the problem which cannot be said to be satisfactorily or finally solved so far. I cannot help feeling that the road engineer in this case has been dominated too much by the ideas of size and shape which were suitable, nay, almost necessary, in the case of wooden blocks where any large increase in the size of the block would entail relatively much larger cost, and difficulty in obtaining suitable wood from which they could be cut. This consideration does not apply to a manufactured rubber block, and it would seem that the use of rubber blocks in very much larger and heavier individual units would give equivalently greater adhesion to the road bed, fewer joints and generally greater stability. I am very strongly of the opinion that a road surface built up in this way from large blocks would overcome the remaining difficulties of rubber road construction, and consider that some trial should be made in this direction.

It is not, however, to the white races alone that the utilisation of rubber in novel ways is confined. The Chinese have for long been famous as an ingenious race, and though the new use I am about to introduce to you is not a case of "Ways that are dark and tricks that are vain" yet it is clearly a case of "Chinese is peculiar." A firm in Singapore, Messrs. Chin Seng Hin and Co., have concocted and put on the market a rubber compound which when softened by heat and spread on a board will like birdlime snare the unwary bird, beast or insect which may cross the too hospitable threshold. Rats and mice stick to it closer than a brother, and the trouble I understand is not so much getting them on to it as getting them off again.

A use of rubber by high art concealed from the public, but at the same time flaunted in their faces when they go to the "pictures" lies, in both senses of the word in the manufacture of theatrical properties for motion picture production.

Rubber sharks and octopuses add to the tragedies of marine disaster, prehistoric monsters puncturable by a bodkin, swords, battle-axes, maces and all the paraphernalia of the rousing cinema battle are made of harmless rubber and a rubber uddered cow gives milk, or some other substitute in unlimited supply.

A new form of rubber termed Onazote consists of rubber expanded into a spongy condition by gas under pressure, but differing from ordinary rubber sponge in that the cavities are unbroken, and remain filled with gas under pressure. The rubber itself is vulcanised and according to the degree of vulcanisation, the resultant product is either a soft resilient substance or a hard expanded vulcanite.

Owing to the extreme expansion which the material undergoes in the special process of manufacture, a product of extraordinarily low specific gravity can be obtained, and furthermore the gas cavities being unbroken and discontinuous, the material acts as a highly efficient non-conductor of heat. When the material was first shown to the public at the Rubber Exhibition at the Agricultural Hall in 1921, great hopes were entertained of its future use, for it does undoubtedly possess qualities which are unique and if it can be prepared in bulk at a reasonable price, there are numerous uses to which it is specially adapted. From the point of view of the producers of raw rubber these hopes have so far failed to materialise.

I have samples on the table of this rubber curiosity, and uses such as floats, shock absorbing cushions and insulators for ice chests and cold storage plants on the large scale are quite obvious from a simple inspection of the material.

PROPAGANDA.

In bringing this paper to a conclusion I realise how totally impossible it has been for me to do justice to the subject of new uses for rubber, not from lack of material but from the profusion of it. Truly it is a case of "not seeing the wood because of the trees."

Rubber is a material which has remarkable properties peculiar to itself, which is capable of conversion by suitable compounding and vulcanisation into materials of such wide range of character and function from elastic thread capable of tenfold extension, to hard tough ebonite taking a fine polish and worked as readily as ebony its prototype, from a spongy foam, the lightest of all solids—built up of cells that imprison self-expansive gas, given us by nature as a milk, a colloidal water emulsion, finer and more perfect than any artificial product.

Rubber is the handmaiden to all modern arts and crafts, transport by land or sea or air is made safe and easy by its means. In truth it seems to me a harder task to find a field of work or play in which rubber does not take its necessary place and share than it is to find a needle in the haystack. In spite of this multiplicity of uses, it must be recognised that rubber in most instances is in use as an adjunct, in a subordinate capacity, as a component part but not the principal or bulkiest component. In road transport tyres of rubber are far and away the best, but they represent only a small part of the road vehicle. So far in the thousand and one articles in whose existence rubber plays a part it will be found that rubber is mostly an accessory—the air brake tubing of the train, the washer in the tap, the cushion of the billiard table, the proofing of the mackintosh.

The world in the last four years has seen a bigger supply of rubber produced than it has been able to consume. To fit consumption to production by developing new uses has been the aim of growers of the raw product, and the Rubber Growers' Association in 1919 organised a competition in which prizes were offered for suggestions for new uses for rubber.

The competition was given the widest publicity and over 2,000 individuals sent in some 10,000 suggestions, which covered a very wide range of subjects and certainly embodied many new ideas. These have all been collated and are now published in a classified form for reference and use, but no outstanding suggestion for any practicable new use of rubber in bulk was put forward. That the use of rubber was stimulated and invention hastened by this campaign I have no doubt whatever, but the general result shows that bulk consumption of rubber for existing uses must follow the development of industry and civilisation as a whole. There is no close or direct relation between the world's capacity for production and consumption, and the collapse in 1921 and 1922 of the price of raw rubber to far below the figure at which substitutes and reclaimed rubber were an economy in manufacture did not seem to lead to greater bulk consumption. What the rubber producing industry needs, and what I have been actively seeking for many years is a use for rubber on the big scale which will function as a practicable proposition with raw rubber at some pivotal price, say 1/6 per lb. In seeking a cure for over-production it is little good turning to the development of any use of rubber if it merely fills the role of accessory or small percentage component of some other article, but it must be on the lines of an article where the chief bulk or cost is rubber that the cure for the evils of over-production must be sought, and where the manufacture and use of it will only be an economic proposition with the price of raw rubber at or below some fairly well defined pivotal figure.

A use for rubber of such a character as this would play the part of an efficient fly-wheel or governor in the conomic machine, lifting dead-weight of excess production from the market and being cut out or ceasing to function when there occurred a pronounced demand for rubber from other directions, and when prices rose in consequence.

To find such a use is the rubber problem of the day to which all other problems and difficulties in the rubber world are secondary.

I can tell you where the solution to the problem will not be found. It will not be in rubber soles. They may absorb the present surplus, if any now be left; they may in future account for some potential surplus assuming full production in force from existing sources of supply, but their use or disuse will not depend upon any pivotal price of raw rubber, the cost of the rubber on the shoe being but a small factor in the price of the shoe itself. It will not be found in the trade in small rubber sundries—in surgeon's gloves or aprons—in rubber acorns for window blinds or rubber stops for doors. Though the whole world combine to make mistakes the use of india rubber for erasion of them will still be a feather in the scale.

Tyres, which now consume seven-tenths of all the rubber produced are made and worn away with little reference to the balance of supplies of rubber, or of cotton or of oil.

The one direction in which I see a gleam of light by which this problem may be solved points down a broad but silent road. I see rest for tired feet, repose for jangled nerves, speed in security for restless passengers along that highway paved with the trickle, the tide or the flood of rubber brimming over from nature's generous forest spring. That may be the golden age when the streets of the great cities are paved, with gold? No! With rubber.

DISCUSSION.

The Chairman (Sir Stanley Bois) confessed, as one deeply interested in the greater consumption of rubber, that the general effect of the paper had been somewhat depressing to him. Mr. Burgess pointed out what was undoubtedly very true, namely, that the extreme durability of the product was calculated to militate very seriously against its extensive consumption in the matter of footwear. Those who had been seriously affected by the slump in prices which had occurred in 1921-22, realised that a weak feature in the position of the industry was its very great dependence upon the motor trade for the main consumption of its product, the motor trade consuming some 70% of the whole output. The enormous improvement which had resulted from the substitution of cord fabric for the old fabric used in building up the body of the tyre, and the consequent much greater durability of the tyre had precluded that extension in the use and actual consumption of rubber which might otherwise have taken place. He was bound to say that he thought to that fact was to be traced a good deal of the lack of demand which had been experienced for increasing supplies.

With regard to the use of crepe rubber soles, their great value for sports purposes had been sufficiently demonstrated; and he thought there would be seen an immense extension of the use of crepe rubber soles for ordinary footwear. It might be of interest to the audience to know that the Propaganda Department of the Rubber Growers' Association had now an experiment in progress in that connexion. They had equipped some 50 postmen in Scotland, who had a long daily round, with crepe rubber-soled boots, which could be sold at competitive prices with ordinary leather-soled boots. The Department were now awaiting the return of some of those boots after the first three months' wear. They were also looking to the return of a further lot after six months wear, and further lots subsequently, so that they might get a really good test of the durability of the boots for that particular purpose.

Dr. H. P. Stevens said that, although Levea latex had been available for the last 15 years, until comparatively recently, nobody had used it; but rubber manufacturers, particularly in the United States, had now realised the potentialities of rubber latex, and were taking steps to obtain benefit therefrom.

He would like to make a criticism with regard to the addition of mineral and other ingredients to latex with a view to manufacturing for the preparation of raw rubber containing those ingredients. Reference had been made in the paper to the Hopkinson process, and it was stated that the method "holds out promise of providing a more easy preparation of a considerable range of moulded rubber goods, owing to the facility with which compounding ingredients may be more intimately mixed with the latex, and precipitated with the rubber in the snow or dried spray." Personally, he did not see why there should be any greater facility in the preparation of rubber goods by that process than by the ordinary processes at present in use. Whether one sprayed or coagulated the latex, one had to add mineral ingredients, and the methods adopted would be the same in both cases. A number of experiments had been made by adding mineral ingredients to latex and coagulating it, and one undoubtedly did get a raw rubber in that way which contained the mineral and other ingredients very uniformly distributed throughout the mass. The difficulty, however, which he had found was that directly one got appreciable quantities of finely-divided mineral ingredients, like china clay, into a mass of rubber which had been coagulated and unworked, the rubber so obtained was so hard that it could not be broken down and used for mixing in with other rubber for the purpose of the manufacture of rubber goods.

The author spoke of the United States Rubber Company as being responsible for the method of preparation of crude dry rubber by the spraying process. He did not desire to enter into the question of priority, but there were two or three other spraying processes in the field.

Mr. B. D. Porritt said his first thought on listening to the paper had been that there was really nothing new under the sun, but that was perhaps incorrect, and the true inference to be drawn was that a long period usually intervened between the making of a suggestion and its being brought into practical use.

In considering the question of the direct employment of latex, one had to go back almost to prehistoric times, when this was originally used by the natives for waterproofing their garments.

In the early days of manufacture in Great Britain, when Thomas Hancock started work, the initial problem was the supply of solvents, and practically the first thing which Hancock did was to investigate the possibilities of latex. His second and third patents dealt with the direct use of latex, in the first case for the manufacture of a leather substitute, and in the second case for the preparation of ropes and cordage. The difficulty which arose in those days, and which had prevented any practical application being made of these patents, was the fact that it was then impossible to import latex without fermentation.

In Hancock's book it is stated that in 1852 an American discovered the use of ammonia as a preservative, and Hancock describes various experiments which he made in connexion with the subject after that date.

With regard to the use of crepe rubber for soling, in his first patent in 1820, Thomas Hancock claimed the use of sheets of rubber cut from the "bottles" of Para for boot soles.

Emphasis has been recently laid on the importance of using only plantation-prepared crepe for soling. Personally, he would not like to express any definite opinion on this point, but he was inclined to think that the material manufactured at home from standard plantation crepe, would be found to be a quite satisfactory product, and, indeed, he very much doubted whether this could be differentiated from that prepared on the estates.

Mr. Walter C. Hancock said it was with a great deal of diffidence that he ventured to make any remarks on the subject of rubber, because it was only by reason of his family connexion that he had any right to speak on the matter. The first impression produced by the author's paper, so far as the extended use of the raw material was concerned, was a somewhat disappointing one. He entirely agreed with the Chairman that one of the inherent difficulties in the whole subject was that the durability of rubber was itself, from the rubber producers' point of view, its great drawback. The only extended use which he could see for the use of rubber at the present time was in its application as a road material. Its use as rubber soles was distinctly limited. Mr. Porritt had already referred to the work of his great-uncle. On looking back on the history of the manufacture of rubber, it was rather strange that 100 years after Thomas Hancock's original patent had been taken out there were practically no new uses for rubber, excepting those which had very largely arisen from the development of new and fresh industries which had been unknown in Thomas Hancock's day. It was the development of industries throughout the world which would probably lead to an increased consumption of rubber.

Mr. M. S. Parry remarked that everybody seemed extraordinarily pessimistic, but his belief was that if all connected with the rubber industry did their utmost and proceeded on the right lines, they would be just as successful now and in the future as they had been in the past. Everybody who had spoken had overlooked the fact that we had just gone through a very big war, and that the whole world was topsyturvy. When the world ceased to be topsyturvy his own belief was that the various uses of rubber and the new uses of rubber would have a very great effect throughout the whole of the Continent. He congratulated the Propaganda Department on the excellent work it had done and was doing, especially in drawing attention to the advantages of rubber for soling boots. For the same reason that America used so much rubber owing to the snow, so, he believed when Russia got on her feet again, she, in turn, would buy rubber in order to sole boots. In order to consummate the excellent work of the Propaganda Department, he thought the Rubber Growers' Association should go one step further and create a consultative body, which should follow up the work of the Propaganda Department, and supply all possible information to those various countries as to how to obtain rubber soles, where to put them on, etc. We had had a great deal of difficulty in learning that even in this country. He therefore suggested that some sort of organisation as he had suggested should be set up, and which should embrace everybody who had experience in the matter, even the bootmaker. In that way the uses of rubber soles would be enormously extended. He urged, also, the rubber companies to put before their shareholders the desirability of wearing nothing else but rubber-soled footwear.

Dr. Rushton Parker asked if everything possible had been done to treat india-rubber in such a way as to make it withstand sea water, so that it might supplant gutta-percha for submarine cables. Was it conceivable also that any plan could be invented by which the surface of stone buildings in London might be treated with some kind of preparation of india-rubber so as to save places like the Houses of Parliament ?

Mr. R. à-Ababrelton said in this country what political people required at the present time were new houses. But we were told there was a shortage of bricks. The author had referred to the use of rubber bricks in road-making. Was it at all possible to manufacture rubber bricks which could be used to build houses ? Could not the Propaganda Department make experiments so that eventually rubber houses in some form or another might be erected in this country?

The author had stated that rubber was useful in connexion with roofs. In South Africa and other tropical countries galvanised iron, zinc and such metals were used for roofs. The result was that the rooms became tremendously hot. Was it possible to substitute a roof made of rubber for a roof made of galvanised iron in such countries ?

Mr. H. E. Miller (Vice-President, Rubber Growers' Association) said that the planting of rubber had been conducted very largely by British enterprise, and yet a surprisingly small proportion of the use and manufacture of rubber goods was carried out in this country. Previous speakers had stated what a conspicuous part British scientists had played in inventing new uses for rubber and the best means of treating it, and he was quite sure there were many brains to-day thinking out possible developments and new uses of rubber. He was not a pessimist. He was certain that in this country there were men of science and practical men who would in one way or another invent new uses for rubber, which would re-establish the plantation industry, and give the world the benefit which it would undoubtedly derive from every new application to which rubber was put.

There was no doubt that rubber was the very best road surface. The problem, however, which had yet to be solved, was how to keep such a road water-tight. Whether " Vultex " or anything else was going to solve that problem or not, he did not know, but if everybody would focus his attention upon it he was convinced that before very long rubber would be used in extensive quantities for road paving purposes.

Mr. D. F. L. Zorn said he had had the privilege of sitting under the Chairmanship of Sir Stanley Bois on the Propaganda Committee of the Rubber Growers' Association for some considerable time past, and he desired to say that when Sir Stanley accused himself of being a pessimist on the question the audience were not to believe him. Sir Stanley perhaps might express verbally a little pessimism, but he could inform the audience that the amount of work which he had done in the way of propaganda to bring about increased uses of rubber was simply tremendous. He could only wish that there were more such men in the industry. The same was true of Mr. Burgess. Those two gentlemen were much too modest to state what they were doing themselves, and he had, therefore, felt it incumbent upon him that he should make the information known.

Mr. Porritt struck a very correct note when he said that there was a long interval between ideas first being thought of and being brought to practical application. It was interesting to note that the direct employment of latex had been thought of 100 years ago. He thought it would be found in very much less than 100 years hence that the direct employment of latex would be a thing which would bring about an enormously extended use of rubber. There had been an interesting article in an American journal on that point, in which the writer had pointed out that the use of latex was likely to be found very valuable indeed in industries which, up to the present, had never been associated with rubber in anybody's mind. The writer had given one or two illustrations of that. One was the substitution of latex for what were known as the drying-out oils, such as linseed oil. It was pointed out in that article that in such directions as those there were tremendous openings for the direct use of latex. Personally, he thought that what would probably happen would be that before very much longer there would be found developing side by side with the old rubber industry another series of industries, all of them occupied with the direct employment of latex, which would demand vast quantities of rubber. From the point of view of the rubber planter or producer, it really did not very much matter whether rubber was used as latex or whether it was coagulated and used as rubber.

Mr. Morland M. Dessau said the use of rubber for roadway purposes had been retarded on account of the work hitherto done proving unsatisfactory. He himself believed that such a difficulty was easy of solution. In order to obtain a perfect rubber roadway it was necessary, to his mind, to have competent bodies examining and reviewing plans which various inventors had for the laying of a roadway. He suggested that the Rubber Growers' Association should establish a competent body to review the different methods of roadway construction. He himself had seen several different systems of varying degrees of merit. One great difficulty was in getting a water-tight roadway, but such a difficulty was not insurmountable. He was afraid that up to the present time those who had been trying to solve the problem had received but very little encouragement, on the ground that there were no funds available by which to carry out experiments. Personally, he should have thought that those interested on the planting side could well afford even to squander a considerable amount of money, in order to try out the various schemes until they had found one which was successful. Even if 99 schemes proved to be failures, if the hundredth proved to be a success, the outlay would have been more than justified.

The Author, in reply, said it had been very far from his intention to have cast a gloom over the assembly. He was an absolute optimist as to the future of rubber. All he had desired to do was to focus attention on new uses for rubber in bulk. At present rubber always appeared as a little piece of something else. There were many things in which ounces of rubber were used, but practically none in which thousands of tons were used, other than in tyres.

As to getting shareholders to consume rubber, there were a quarter of a million shareholders. If each one of them used up 10 lbs. of rubber a year, that was about 3 or 4 ounces a week, and they would find themselves hard put to it to destroy 4 ounces of rubber a week; but supposing each shareholder did use up 10 lbs. of rubber a year, it would amount to 1,000 tons; and, as against that, a few years ago there had been dumped in this country an excess production of 40,000 or 50,000 tons in the year. Of course, every little helped, and he did not minimise the effect of the extension of small uses of rubber: but it had to be remembered that 70 per cent. of the world's rubber was used on motor-cars at the present time. If they could extend the use of motor-cars then more could be done for the extension of the use of rubber than in any other way, but the Rubber Growers' Association had felt that to deal with the extension of the use of motor-cars was really entirely beyond its province.

Dr. Stevens had referred to the question of the facility which Hopkinson found in making moulded goods from his snow. He thought the point was as follows. When the stuff fell to the bottom of the settling chamber, Hopkinson obtained a material which was about eight inches thick. When it was put under hydraulic pressure it came down to a slab of about 1½ inches thick. It was during the compression of that dry material that Hopkinson found the facility of forming moulded goods. If Hopkinson was able to get his snow made up of rubber compounded with the materials he required, then moulding could take place from the snow itself. He thought that was the point—that there was no need for breaking up by mastication before the moulding took place.

Dr. Stevens asked how Hopkinson vulcanised the moulded goods.

The Author replied that he vulcanised them after they were compressed. He moulded them and vulcanised in the mould.

With regard to the question of the use of rubber for submarine cables, he did not anticipate that rubber would ever quite oust gutta-percha. It was a different gum altogether.

With regard to the use of rubber bricks for building houses, it had to be remembered that bricks made of rubber, or bricks used for roadways, cost something like 2/6 a piece, and if people had to buy bricks with which to build houses at 2/6 a piece they would have no income left with which to live.

There might be certain uses for rubber in connexion with roofing, perhaps in some artificial or composite roofs. If, for instance, the expanded rubber "Onazote" could be prepared cheaply on a large scale, it would be a splendid substance for putting underneath the galvanised iron roofs used in tropical countries, because it was such an excellent non-conductor of heat or cold. One of the big uses suggested for it was for lining refrigerating rooms, where it was essential to keep the heat out or to keep the cold in.

Mr. R. à-Ababrelton asked if there was any chance of such a rubber melting on account of the tremendous heat experienced in tropical countries.

The Author replied that the rubber would not melt if it had been vulcanised.

A hearty vote of thanks was then accorded to the lecturer for his interesting and valuable paper.

Mr. J. Fairbairn said he was sure the audience would not like to depart without according a cordial vote of thanks to the Chairman. It had been said that Sir Stanley devoted a certain amount of time to the Rubber Growers' Association. Personally he had sat on the Propaganda Committee, and he had often wondered what amount of time Sir Stanley gave to his own business. In fact, he had come to the conclusion that either Sir Stanley was a very wealthy man or an extreme enthusiast. Greater enthusiasm was needed from those at the head of affairs. There must be greater pooling of interests and greater combination. He had no doubt that if they all stood together and worked together and fought together, big new uses for rubber would come along.

The vote of thanks was carried unanimously.

The meeting then terminated.

OBITUARY.

Albert Francis Wenger.—Mr. Albert Francis Wenger, who was elected a Fellow of the Royal Society of Arts in 1919, died on February 25th, in his 87th year. He was born at Lausanne, and as a boy he went to the factory of an uncle in Milan, a well-known pottery manufacturer. He became manager of the firm, but subsequently set up in business on his own account in Naples. In 1862 he visited London at the instance of the Municipality of Milan, to report upon the ceramics shown at the Exhibition. On this occasion he visited the Staffordshire potteries, and became so much interested in them that he decided to settle there. This he did in 1869, beginning as a modeller for the Worcester and other factories. He then started colour-making on a small scale at Cobridge; later he moved to Hanley, and in 1900 the present large works were built at Etruria. At his factory, he had a valuable collection of historic ware, from Egyptian days down to the present time; and at his home he had a large collection of prints and pictures. He was both a practical potter and a connoisseur, and he was one of the most able and remarkable men in the pottery trade. He introduced numerous improvements in pottery manufacture, including vaporisers for spraying colours on to the ware and liquid gold. Before the War his was the only firm that manufactured liquid gold in England. He was also the first manufacturer of lustres in England.

Sir John Stewart-Clark, Bt.—The death took place on March 3rd of Sir John Stewart-Clark at his residence, Dundas Castle, Midlothian. Born in 1864, he was educated at Merchiston Castle School, Edinburgh, and Jesus College, Cambridge. He succeeded to his father's interests in the great thread combine of Coats and Clark. A man of great wealth, he contributed large sums to charitable objects, and was on the boards of various hospitals and similar institutions. He was a member of the Royal Company of Archers, King's Bodyguard for Scotland. A baronetcy was conferred on him in 1918.

Sir John was elected a Life Fellow of the Royal Society of Arts in 1913.

GENERAL NOTES.

Formosa.—Dr. T. Baty in a recent issue of the *Contemporary Review* gives us an attractive picture of this far eastern centre of sugar and camphor production. "If a European were suddenly set down in Taihoku and invited to guess where he was, Formosa is the last place that would occur to him. We think of the island as it was thirty years ago—a 'nooks-hotten' place of sugar shanties and hovels fringing the virgin mountains. . . . . . ., the great solid palaces marble-lined, the well paved roads, the villas and hospitals. Little is known in the West of the energy and enterprise with which the Japanese have set to work to create modern conditions in their new possessions." Askao (now called Heito)—one of the smaller towns—is an important sugar centre with the central factory of the Formosan Sugar Company. The big camphor works are at Taihoku, and travelling into the hills by the Arisin scenic railway one sees the forests which are the source of much wealth. Formosa has more than half a million acres of rice lands. The first crop for 1923 was nearly 13 million bushels.

The Esthonian Glass Industry.—According to information received by the Esthonian Central Statistics Bureau, approximately 386.3 tons of window glass and 1,500,000 bottles and glass articles were manufactured in Esthonia during 1922. The glass factories were closed down during the war. In 1919 and 1920 the Jarvakandi factory was the only one working. In 1921 three were in operation, which in 1922 had increased to four. The following glassware was imported in 1922: Bottles and jars, 626.6 tons; window glass, 478.8 tons; mirror glass, 19.1 tons; other glassware, 507.2 tons. The total output of the Esthonian glass works is consumed in the country, and still a great deal of glass is imported. This seems to show that there are big possibilities for extending this branch of industry in Esthonia.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

March 19.—R. L. Robinson, Forestry Commissioner, "The Forests and Timber Supply of North America." Lord Clinton will preside.

March 26.—Neal Green, "The Fishing Industry and its By-Products." Professor E. W. MacBride, D.Sc., F.R.S., will preside.

April 2.—Sir Lynden Macassey, K.B.E., "London Traffic." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

April 9.—Frank Hope-Jones, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." Professor C. Vernon Boys, F.R.S., will preside.

April 30.—Brigadier-General Sir Henry Maybury, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "The London Dock District and its Roads."

May 5 (Monday).—T. Thorne Baker, "Photography in Industry, Science and Medicine."

MAY 7.—J. ROBINSON, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation." ADMIRAL OF THE FLEET SIR HENRY JACKSON, G.C.B., K.C.V.O., F.R.S., will preside.

MAY 14.—

MAY 21.—PROFESSOR C. VERNON BOYS, F.R.S., "Calorimetry." (Trueman Wood Lecture.)

MAY 28.—MRS. ARTHUR MCGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons, at 4.30 o'clock :—

MARCH 21.—OTTO ROTHFELD, I.C.S., "Progress of Co-operative Banking in India." LORD LAMINGTON, G.C.M.G., G.C.I.E., will preside.

MAY 2.—JOCELYN F. THORPE, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced :—

BHUPENDRA NATH BASU, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

Monday or Tuesday afternoons, at 4.30 o'clock :—

MAY 27.—C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

June 16.—C. V. Corless, M.Sc., LL.D., "The Mineral Resources of Canada: The Pre-Cambrian Area."

COBB LECTURES.

Monday evenings, at 8 o'clock :—

DR. T. SLATER PRICE, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, MARCH 17 .. British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. H. Bagenal, "Planning for Musical Requirements."

Geographical Society, Lowther Lodge, Kensington Gore, S.W., 5 p.m. Col. H. St. J. L. Winterbotham, "The Choice of a Grid for British Maps."

Electrical Engineers, Institution of, Victoria Embankment, W.C., 7 p.m. (Informal Meeting.) Messrs. L. Gaster and J. S. Dow, "Illuminating Engineering, its Application and Value to the Electrical Industry."

University of London, at King's College, Strand, W.C., 5.30 p.m. Rev. C. F. Rogers, "Ecclesiastical Music." (Lecture VII.)

5.30 p.m. Dr. R. W. Seton-Watson, "A Study of Bohemian History." (Lecture VII.)

At the Institution of Civil Engineers, Great George Street, S.W., 5 p.m. Mr. O. C. A. van Lindth de Jeude, "Practical Hydraulic Engineering Problems in connexion with Navigation." (Lecture IV.)

Birmingham University Chemical Society, Edgbaston, Birmingham, 5.30 p.m. Mr. R. L. Wormell, "Ionisation in Non-Aqueous Solvents."

Rubber Industry, Institution of, Midland Hotel, Manchester, 7.30 p.m. Captain E. E. Buckleton, "Selling Rubber Goods."

East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Sir Alfred Chatterton, "The Utilisation of Underground Water in India."

TUESDAY, MARCH 18 .. Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m. Mr. A. W. Flux, "The Census of Production."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. R. W. Chambers, "Civilisation and Literature of the Anglo-Saxon Period." (Lecture II.)

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. G. W. Johnson, "The Development of the Marine Steam Turbine."

Mineralogical Society, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Prof. F. G. Parsons, "A Comparison of Cranial Contours."

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, Piccadilly, W., 4.30 p.m. Major G. Home, "Some lesser-known Roman Towns in Tunis and Algeria."

Metals, Institute of (Local Section), Chamber of Commerce, New Street, Birmingham, 7 p.m. Mr. D. Bunting, "Brittle Ranges in the Brasses."

Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 5.30 p.m. Mr. E. Falconer, "Relative Efficiency of Horse and Mechanical Power for Road Transport."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. J. C. Dolman, "An Appreciation of the Beautiful."

University of London, at King's College, Strand, W.C., 5.30 p.m. Prof. Hans Driesch, "The Possibility of Metaphysics." (Lecture III.)

Embroiderers' Guild, at the Victoria and Albert Museum, South Kensington, S.W., 3 p.m. Miss Laura Start, "The Weaving and Textile Designs of the Ibans or Sea Dyaks."

Chemical Industry, Society of (Local Section), University Buildings, Birmingham, 7.15 p.m. Mr. A. W. Knapp, "The Fermentation of Cacao."

Hull Chemical and Engineering Society, at the Photographic Society, Grey Street, Park Street, Hull, 7.45 p.m. Dr. W. Thevenaz, "Anthracene and its Derivatives."

WEDNESDAY, MARCH 19 .. London County Council, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Sir Napier Shaw, "Modern Meteorology." (Lecture IV.)

Meteorological Society, 49, Cromwell Road, S.W., 7 30 p.m. Prof. V. H. Blackman, "The Influence of Electricity in the Growth of Plants."

Oriental Studies, School of, at the London Institution, Finsbury Circus, E.C., 5 p.m. Prof. Sir E. Denison Ross, "Old Calcutta."

Transport, Institute of, (Local Section). The University, Manchester, 5.30 p.m. Sir Philip Nash, "Transport Problems."

United Service Institution, Whitehall, S.W., 3 p.m. Captain G. O. Stephenson. "The Submarine Campaign in the Mediterranean subsequent to 1916."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Major A. G. Church, "Science in Industry."

University of London, University College, Gower Street, W.C., 6 p.m. Prof. Karl Pearson, "The Current Work of the Biometric and Eugenics Laboratories." (Lecture VI.)

At King's College, Strand, W C., 5.30 p.m. Prof. Hans Driesch, "The Possibility of Metaphysics." (Lecture IV.)

5.30 p.m. Dr. W. C. Bolland, "The Book of Assizes."

At the Institution of Civil Engineers, Great George Street, S W., 5 p.m. Mr. O. C. A. van Lidth de Jeude, "Practical Hydraulic Engineering Problems in connexion with Navigation." (Lecture V.)

THURSDAY, MARCH 20 .. Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. W. S. Farren, "The Work of the Aeronautical Research Committee's Panel in Scale Effect."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. D. S. M. Watson, "Evolution to-day." (Lecture I.)

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Linnean Society, Burlington House, Piccadilly, W., 5 p.m.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. (1) Messrs. P. C. Austin and V. A. Carpenter, "Rotatory Dispersion of Derivatives of Tartaric Acid.—Part I. Methylene Derivatives." (2) Messrs. T M. Lowry and J. O. Cutter, "The Rotatory Dispersive Power of Organic Compounds. —Part XV. The Molecular Weight of Ethyl Tartrate and the Origin of Anomalous Rotatory Dispersion in Tartaric Acid and its Derivatives."

Physical Society, at the Institution of Electrical Engineers, Victoria Embankment, W.C. Jubilee Celebrations. 3 p.m. Reception.

3 45 p.m. (Guthrie Lecture), M. le Duc de Broglie, "Photo Electric Effects in the Case of High Frequency and Allied Phenomena."

6 p.m. Sir Richard Paget, "The Nature and Reproduction of Speech Sounds."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p m.

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. M. Emile Cammaerts, "Education in England and Belgium Compared."

London County Council, at the Geffrye Museum, Kingsland Road, E., 7.30 p.m. Mr. H. P. Shapland, "Furniture —the Development of the Parlour."

University of London, at King's College, Strand, W.C., 5.30 p.m. Dr. A. R. Pastor, "Spanish Mysticism." (Lecture IV.)

5.30 p.m. Prince D. S. Mirsky, "The History of Russian Literature." (Lecture IX.)

5.30 p.m. Prof. W. C. Buckland, "The Classical Roman Law: Recent Investigations." (Lecture I.)

Structural Engineers, Institution of, 296, Vauxhall Bridge Road, S.W., 7.30 p.m. Mr. H. J. Davey, "The Inspection and Testing of Structural Materials."

Tropical Medicine and Hygiene, Royal Society of, at the Royal Army Medical College, Grosvenor Road, S.W., 8.15 p.m. Laboratory Meeting and Demonstrations illustrating the Etiology and Prevention of Malaria, etc.

China Society, at the School of Oriental Studies, Finsbury Circus, E.C., 5 p.m. Miss E. G. Kemp, "Up and Down in Shansi."

FRIDAY, MARCH 21 .. Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. (1) Mr. G. P. Garbett, "The Use of Light for Outdoor Advertisements." (2) Miss M. Partridge, "The Use of Light in Shops, in Show Windows and for Display Purposes."

Royal Institution, Albemarle Street, W., 9 p.m. Prof. Sir F. Keeble, "The Plant Commonwealth and its Government."

Physical Society, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 4 p.m. Jubilee Celebrations continued.

Photographic Society, 35, Russell Square, W.C., 7 p m. Mr. L. Richmond, "My Experiences in Venice."

Medical Officers of Health, Society of, 1, Upper Montague Street, W.C., 5 p.m. Dr. W. A. Daley, "The Organisation of Propaganda in the Interests of Public Health."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Presidential Address by Mr. W. H. Patchell.

Engineers, Junior Institution of, 39, Victoria Street, S.W., 7.30 p.m. Mr. P. Parrish, "Sulphuric Acid Plants—New and Old: Constructional Details and Working."

University of London, at King's College, Strand, W.C., 5.30 p.m. Senhor Rangel de Castro, "The Civilisation of Brazil." (Lecture I.)

5.30 p.m. Dr. F. Pavlasek, "Social Conditions in Czecho-Slovakia."

At University College, Gower Street, W.C., 5.30 p.m. Dr. W. Seton, "The Relations between Scotland and England in the Sixteenth Century." (Lecture IV.)

At the Institution of Civil Engineers, Great George Street, S.W., 5 p.m. Mr. O. C. A. van Lidth de Jeude, "Practical Hydraulic Engineering Problems in Connexion with Navigation." (Lecture VI.)

SATURDAY, MARCH 22 .. King Edward's Hospital Fund, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C.; 5 p.m. Mr. Allen S. Walker, "Old London and How to See it." (Lecture II.)

London County Council, at the Horniman Museum, Forest Hill, S.E., 3.30 p.m. Mr. H. N. Milligan, "The Natural History of Subterranean Animals."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. Sir E. Rutherford, Properties of Gases in Vacua." (Lecture IV.)

Journal of the Royal Society of Arts.

No. 3,722. VOL. LXXII

FRIDAY, MARCH 21, 1924.

All communications for the Society should be addressed to the Secretary, John St[illegible] *Adelphi, W.C.*[illegible]

5 MAY 1924
R. I. P. U. B.

NOTICES.

NEXT WEEK.

Monday, March 24th, at 8 p.m. (Cobb Lecture). **Dr. T. Slater Price**, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." (Lecture I.)

Wednesday, March 26th, at 8 p.m. (Ordinary Meeting.) Neal Green, "The Fishing Industry and Its By-Products," Professor E. W. Macbride, D.Sc., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 12th, 1924; Sir Herbert Jackson, K.B.E., F.R.S., in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Campbell, Andrew, Beckenham, Kent.
Sharp, Mrs. Katharine Dooris, London, Ohio, U.S.A.
Williams, Professor Clement Clarence, Urbana, Illinois, U.S.A.

The following candidates were duly elected Fellows of the Society:—

Bruce, Oswald B., Weston-super-Mare.
Haunz, Charles F., M.Am.Chem.S., Buffalo, New York, U.S.A.
Howgrave, Arthur Atherfold, London.
Porro, Thomas Joseph, Tacoma, Washington, U.S.A.
Shallenberger, Professor Garvin Dennis, Montana, U.S.A,
Vaid, Bakhshi Dina Nath, Rawal Pindi, India.

A lecture on "Personal Recollections of Some Notable Scientific Men" was delivered by Mr. **Alan A. Campbell Swinton**, F.R.S., late Chairman of Council.

PROCEEDINGS OF THE SOCIETY.

TWELFTH ORDINARY MEETING.

Wednesday, February 27th, 1924.

Sir Robert Blair, LL.D.

(Education Officer, London County Council), in the Chair.

The Chairman, in introducing the lecturer, said Dr. Myers was now recognised, both in this country and abroad, as the leading psychologist in Great Britain. He was at one time Professor of Psychology at King's College, London; and, later, Lecturer in Experimental Psychology at Cambridge. At Cambridge his initiative and generosity secured the building and equipment of the new Psychological Laboratory; and for some time he was its director.

During the War he became Consulting Psychologist to the British Expeditionary Force, serving as a lieutenant-colonel in the R.A.M.C. The War turned his interest and attention from problems of pure or abstract psychology to its more practical applications, particularly in medicine and industry. On the conclusion of the war, by enlisting the interest and support of eminent men of business and science in the new possibilities of psychological methods, he founded the National Institute of Industrial Psychology, and shortly afterwards gave up his post at Cambridge to become the Director of that Institute. As its Director, and as a member of the Industrial Fatigue Research Board (a Government Department under the Privy Council) he had organised and assisted in many investigations in industrial psychology. Research students and psychological investigators, working under his guidance, had carried out numerous fruitful experiments and enquiries in large firms throughout various parts of the country, and, more recently, in trade and other schools in London and elsewhere. He had of late become especially interested in the possibility of vocational guidance for children leaving schools; and last January obtained from the Carnegie Trustees a grant of £6,000 for carrying out an experimental investigation into the practicability of such a scheme.

The following paper was read:—

THE USE OF VOCATIONAL TESTS IN THE SELECTION OF A VOCATION.

By Charles S. Myers, C.B.E., M.D., Sc.D., F.R.S.,
Director of the National Institute of Industrial Psychology.

By "vocational guidance" is meant the advice given to the worker, based on systematic examination of his mental and bodily condition, as to the occupations for which he is fitted and unfitted. "Vocational selection," on the other hand, is the process of choosing, by such examination, those workers best fitted for the vacancies in any one occupation. That is to say, vocational guidance aims at finding the best job for the particular worker, whereas in vocational selection we select the best worker for the particular job. Vocational guidance rests on the assumption that of all occupations some are better suited than others to the mentality and physique of any worker; vocational selection assumes that some workers are better fitted than others to any particular job. No one will deny the truth of these assumptions; the only question at issue is the best means of acting upon them.

Until recently, vocational guidance has been left almost wholly to the individual and his family. The young worker, choosing his life's work, may be influenced by his own interests and desires. A love of adventure may prompt him to go to sea; an instinct for self-display to go on the stage; the ambition to rise in the social scale may lead him to take up office instead of artisan work. Or he may be influenced by similar aspirations on the part of his parents, by their desire that he shall follow his parent's occupation, or shall avail himself of the special influence expected of some relation or friend in a particular vocation. The result is too often disastrous. Because a boy or girl has certain interests or desires in relation to a given occupation, it by no means necessarily follows that he will do well at it. The interests or desires may be confined to a very insignificant aspect of his future work. Thus the love of adventure will not make a good seaman; nor will the desire for self-display make a good dancer or actress. So too, a strongly developed instinct of protection and the emotion of tenderness associated therewith will not suffice for success in nursing, medicine or agriculture; and far more than a strongly developed instinct of constructiveness is necessary to make an efficient engineer. Owing to his natural desires and ambitions, the parent's opinion as to the best vocation for his child is notoriously unreliable; he is apt to be singularly blind to the most obvious signs when they point to a career opposed to his own inclinations.

Of late years, school committees have been voluntarily formed for the purpose; the teacher's knowledge of the child has been invoked; and juvenile labour advisory committees have been established. But until quite recently, none of the work has been conducted in a systematic, scientific fashion. The teachers' reports have not proved sufficiently helpful. Nor has vocational guidance, merely based on interview, proved adequate.

The method of interview has until lately been practically the sole basis of vocational selection. A certain number of vacancies occur in a factory. A larger number of employees apply for them. Recommendations from past employers or reports from the candidate's school may be taken into account, but selection and allotment to different occupations within the factory is commonly based on the results of a brief interview. Thereafter, the engaged employee, if found unsuited for his work and undischarged, is wafted from one department to another, on the principle of trial and error, until he finds work at which he proves successful. Let me at the outset emphasize the fact that I do not for one moment suggest the abolition of the interview. It supplies information which, at present at least, can be adequately obtained in no other way. It affords an excellent idea—and by systematic study of the possibilities of the interview, if scientifically conducted, it can doubtless afford even a *more* excellent idea—of the personality of the candidate, his bearing, address and speech, his honesty, loyalty, leadership, etc. But for successful selection we need far more detailed information than this; and this information is only obtainable by special methods of examination, which must be added to the method of interview. These methods involve medical, physiological and psychological examination of the candidate and are already being applied, as we shall see, by some of the more progressive firms. In a rough way, they have already been applied in the case of certain occupations. The soldier is examined for his eyesight, the sailor and the engine driver for his colour vision, a certain standard of physique is required by the army, navy and air force, and of health in certain occupations. But we need to go much further than this. A large number of tests to which I will later allude are now available, by which we can arrive at an estimate of intelligence, memory, attention in its various forms, the strength, speed, precision, dexterity and control of movement, etc. And a large amount of information can be obtained, both from observation of the candidate's behaviour at the tests, and from questions to the candidate by the examiner, as to other important qualities which are not, at present at least, capable of measurement or submissible to experiment. For this and even more cogent reasons, many of the tests must be applied, or at least their application must be supervised by a properly trained person. The present practice of entrusting colour-blindness tests to examiners untrained in the psychology and physiology of the subject is apt to be at times unsatisfactory. How much more so must it be in testing for other characters far more complex, more intricate and less susceptible of simple, direct measurement. In a very rough way, general intelligence, memory and the like can be determined by the untrained applying standardised tests to groups of subjects, but injustice may be done in individual exceptional cases. Would an engineer place any confidence in the results of a test of brake horse-power carried out by a psychologist or physiologist? How much more unreliable must psychological and physiological tests prove, when carried out by an engineer! Yet this is what educational and industrial authorities are always demanding,—a series of mental and physical tests which can be safely applied without expert supervision, by those untrained in psychology and physiology.

I need hardly lay stress on the immense importance of utilising the best means at our disposal in vocational guidance and vocational selection. What a wastage of time, money and happiness arises from the "round peg" trying to fit the "square hole," and passing by trial and error through a variety of different holes, until at length a hole is found which the peg fits! The employee becomes discontented and dispirited; the employer wastes time and expense in training the employee to work at which he will never do well. If a man is fitted to his work, not only is he happier and more efficient at it, but his health is better, and the sickness records of the factory are immensely improved. Moreover, the enormous wastage at present going on, through workers leaving because they are unfitted for and hence dissatisfied with their job, becomes enormously reduced. It has been truly said that the number of firms in this country who keep a really reliable record of the actual costing of their manufactures is extremely small. Still smaller is the number of those who know the amount of their annual labour turnover and endeavour to estimate satisfactorily and to remedy its various causes,—one of the most potent of which is unsuitability for the job.

The value of systematic vocational guidance at the school-leaving age, and of vocational selection at the factory and office, is fast becoming recognised abroad. In Barcelona, there exists an Institute of Vocational Orientation, supported with an annual grant of about £1,400 from the city and the province, to which boys and girls leaving school are encouraged to apply for a medical, anthropometric, physiological and psychological examination. Students of the Barcelona Municipal Polytechnic are compelled to be examined at the Institute, if they are not making satisfactory progress at their work. In the medico-anthropometric department, measurements are taken of the head, chest, stature, weight, respiratory capacity, visual and auditory acuity; the condition of the digestive, circulatory, excretory systems, etc., is also examined. In the psychometric department tests are applied to determine the intelligence, judgment, memory, attention, imagery, emotionality, speed of reaction, etc., of the subject, and information is sought as to the candidate's interests, ideals, defects, etc. The Institute co-operates with various local Unions or Federations of employees and employers, and has examined into the social and economic condition of about fifty different occupations, including the special physical and mental requirements of each. There are four departments of the Institute, each with a paid qualified expert, and with younger unpaid assistants.

Greater Brussels possesses a rate-supported Inter-communal Bureau for the vocational guidance and apprenticeship of young people. The separate Communes of Brussels are also establishing (three have already been opened) their own Vocational Guidance Bureaux, equipped with the services of medical, psychological and educational experts, who work under the ægis of the Inter-communal Bureau.

In Tokio, a section of the Japanese Association for the Promotion of Industrial Harmony, to which the Government has contributed one-third of its endowment of £800,000, has been established, which is concerned with research in industrial psychology, the provision of training courses for factory managers, the investigation of factory problems, including those of vocational selection, movement and fatigue-study.

Berlin, of course, has its Institute of Vocational Psychology, now a branch of the Institute of Applied Psychology there, and has devised methods of testing compositors, telegraphists and skilled metal workers.

Geneva has its Institut Rousseau, Paris its Institut Lannelongue, Prague its Academy of Labour, all devoted *inter alia* to the problems of vocational psychology.

In the United States, training in vocational psychology is carried out in most of the Universities, the Carnegie Institute of Technology contains a Division of Co-operative Research, in which is included a Bureau of Personnel Research, financially maintained by a group of industrial and commercial firms who obtain and exchange information relating to the selection, training, organisation and supervision of personnel. Indeed, so numerous are the bodies undertaking research and applying it in regard to vocational psychology, that the United States National Research Council has recently organised a Personnel Research Federation, with the objects of creating a clearing house for information on the subject, of avoiding needless overlap by better co-ordination, and of undertaking hitherto neglected advanced research.

Some form of psychological test is applied to their employees by over thirty firms in the United States. In Germany such tests are used by the Allgemeine Elektricität Gesellschaft, the Siemens and Halske and Osram Companies, the Great Berlin Tramcar Company, the German State Railways, the Post Office, etc. All these concerns have installed psychological laboratories in which vocational tests are conducted.

Germany indeed makes no secret of her aspirations, that by concentrating on the *human* problems of industry and commerce she may attain that success in the present century which she won in the past century by devotion to the *mechanical* aspects of the subject.

Let us now turn to the methods of vocational testing. They are broadly three in number. The first may be called the method of 'sample' tests. These are to be found among the tests contained in the following illustration, devised for shorthand and typewriting for the National Institute of Industrial Psychology by Dr. Cyril Burt. He begins with four tests which form part of a scheme of tests of general intelligence, namely, opposites and synonyms, analogies, mixed sentences, and completions.

I may here note that such tests of general intelligence are proving of the greatest practical value. They were employed in the war by the United States Army, where they were applied to over 1,700,000 soldiers, including about 42,000 commissioned officers, for the selection of non-commissioned and commissioned officers and of men for special duties, for the rejection of the mentally unfit, etc. They are now employed to determine the entrance of students at several American Universities, and in certain examinations in our own Civil Service. They are found to be useful in vocational guidance and selection so as to secure the proper standard of intelligence which experience finds to be requisite for different occupations; too high an intelligence in a given occupation often leading to as great inefficiency as too low an intelligence, owing to the tedium and unrest thereby produced. The National Institute of Industrial Psychology has standardised a series of tests for general intelligence, which are being introduced at their request into several of the more progressive firms in this country. The preparation of a series of performance tests, specially adapted for manual rather than for clerical and literary work, is also well advanced.

In the opposites and synonyms test, a list of pairs of words is presented to the candidate, who is instructed to indicate by a mark against each pair, whether they are opposite in meaning or are identical; in the analogies test, he has to underline a fourth word among those given bearing the same relation to the third as the second bears to the first, *e.g.*, cat; kitten as dog; bitch, puppy, hound; in the mixed sentences test a series of short sentences is given, with the words in each sentence arranged in disorder, of which the candidate has to make sense, stating whether it is true or false; in the completion test, a prose passage is given with various words omitted, which the candidate has to supply. A certain time-limit is fixed for each test, which is insufficient for the most intelligent candidate to complete the whole of it. This intelligence test is followed by a test of arithmetic and by one of spelling, in which a list of difficult words is given, some of which are misspelt, which the candidate has to correct where he thinks necessary. Then come two linguistic tests (*i*) of synonyms, (*ii*) of definitions. Finally the candidate is submitted to two 'sample' tests, to present which I have made use of this example. Sample tests are so called because they involve work which is a sample of that which the candidate will be subsequently engaged in his occupation. The first of these sample tests is for shorthand. Six passages are read out to the subject at different prescribed rates,—60, 80, 100, 120, and 140 words per minute being successively read to him. Then a series of unusual words of graded difficulty, exemplifying important principles in shorthand, is given to him, which he has to express in proper shorthand outlines and transcribe back into longhand, no time limit being provided. The second series of sample tests is for type-writing. Five tests are employed,—(1) for speed (*a*) with time limit and (*b*) with amount limit, (2) for accuracy, copying a much corrected manuscript, (3) for display, (4) for tabulation of a complicated list of data, (5) for manuscript reading of two very illegible letters. The entire test lasts two hours, and has been found in practice to correlate highly with the opinions of the supervisors of the clerks. That is to say, when the ranking of the subjects according to their success in these tests is compared with their ranking according to the views of their supervisor, there is a very close correspondence. The tests also allow of the preparation of a list of minimal standards which a candidate must obtain, according as (1) he is needed for work of a high order of intelligence, (2) he is required only for routine work, (3) information is desired as to whether after adequate training he is likely to be fit for practical work, or is unfitted for any work whatever in shorthand and typewriting.

The second method of vocational testing involves the employment not of 'sample' tests, but of 'analogous' tests. Thus, in order to examine workers to be engaged on feeding machines, Link devised a gramophone box on the circular horizontal disc of which he placed a larger metal disc, presenting a small sector which was cut out and the size of which could be varied. This open sector when it passed over a certain spot below would allow of a shot dropped to pass through it into a stationary receptacle beneath. When the disc revolved the candidate had to drop the shot at a precise moment so that the ball fell through the slit into the receptacle. Link found that some workers did better with a slow rate of rotation, whereas others did better with a quick rate; and that this corresponded to their varying industrial efficiency with slow or fast-moving machines which they had to feed. The same individual differences in optimum rhythm of movement were noted in our munition factories during the war, some workers succeeding better with fast, than with slower machines, and others vice versa.

The third method of vocational testing attempts to analyse the various qualities required for success in a given occupation and to test each of these qualities separately, instead of employing the complex 'sample' or 'analogous' tests of the two methods previously described. As an illustration of this method, I will describe an examination of 28 telephone exchange girls by Fonteigne of Strasburg. The tests which he finally selected were those for memory of numbers and names, for accuracy of aim, for speed of reaction, for speed and accuracy of cancellation of given letters wherever they occur in a given sheet of printed words, and for speed and accuracy of card-sorting. I omit for the moment the unsatisfactory results of seven subjects. The remainder correlated very highly in order of success at the tests with the order independently ascribed by the telephone supervisor. I present successively the tests-order and the supervisor's order of ranking. Where two girls, say the 9th and 10th are equal in the tests, they are each given an intermediate rank, 9.5.

1	2	3	5	8	9	10	11	12	13	14	15	19	20	21	22	23	25	26	27
3	2	1	4	5	8	13	7	12	9.5	14	11	16	23	19.5	26	21	22	19.5	25

In such an occupation as telephone-exchange work in which breakdowns are frequent from the strain involved, it is obvious that much suffering could be saved by some such carefully devised methods of selection whereby the unsuited are eliminated at the outset of their career. We are able to measure the correspondence between the ranking by tests and the official ranking by means of a formula giving a co-efficient of correlation. This co-efficient is zero when there is a total absence of correlation; it is +1 when the direct correlation is perfect; and it is —1 when the correlation is inversely perfect, *i.e.*, when the top individual in the one ranking is last in the other, and so on. Between 0 and + or —1 the correlation co-efficient has any value, expressed as a decimal fraction, according to the degree of correlation, direct or inverse. The co-efficient in the above tests for telephone operators was +.698, in Mr. Burt's tests for clerical workers it was +.7.

A few of the telephone operators, as I have said, showed poor correspondence between their ranking according to the tests and according to their supervisor's opinion. Several causes may be responsible for this. The supervisor may have been wrong in his opinion; I shall presently instance a striking illustration of such an error. Or the tests may have been inadequate; there can be no doubt that they are capable of improvement. General intelligence, too, must play some part in telephone exchange work. How important a part remains to be ascertained; but a highly intelligent individual may be able by round-about ways to compensate at her work for deficiency in one or more of the abilities which are determined by these different tests. It will be recalled that some tests, highly correlated with general intelligence, were included in the examination; whereas others, accuracy of aim and speed of reaction, are not correlated with general intelligence. Again, each of the tests is given the same weight in determining the final rank of the operator. But more careful research will certainly discover that some traits are more important for telephone work than others. Consequently instead of determining the final ranking by averaging the ranks in each test, certain tests will need to be "weighted," thus allowing of greater importance being given to them than to others, in the settlement of the final order based on the results of all the tests. Further, the tests need to be supplemented by others, such as the ability to interpret indistinctly heard words. In testing for visual acuity by means of letters, it is found that some subjects are ready to interpret the vague indications suggested by letters really imperfectly seen, whereas others stolidly read only the letters which are clearly visible. So it is with the discrimination of two near points simultaneously applied to the skin. There is a type of person ready to interpret suggested signs, and another type indisposed to do so. Anyone who has ever heard a foreign language through the telephone will realise the importance of the interpretation of indistinctly heard sounds for the most successful telephone exchange work. Moreover, the supervisor may base his opinion of the operators on such factors as obedience, punctuality, patience and courtesy, which the tests fail to take into account, or may be more or less unconsciously prejudiced in favour of or against some particular operator. Indeed, the marvel is that in all these circumstances the co-efficient of correlation should be so high. But we have not yet considered one important factor, which may affect the degree of correspondence in the two ranks,—the factor of interest. One of the seven operators whose ranking differed strikingly in the tests from that of the supervisor, did very well in the tests, but was comparatively low in the supervisor's order of ranking. The latter, when her attention was called to the fact, said, "Well, I am not a bit surprised. The girl could make an excellent telephonist if she only chose."

In its experience in this country, the National Institute of Industrial Psychology has met with similar instances. In one case, the tests devised for the selection of packers gave much better correlation co-efficients when they were correlated with the results of a special speed test of packing applied to the girls, than when they were correlated with the girls' average output as determined by their piece-rate earnings. Nevertheless, this firm estimate that the introduction of vocational tests into its factory has saved it at least £5,000 per annum.

On the other hand, there were one or two cases among the telephone operators, where girls who did poorly at the tests were ranked high by their supervisor. Doubtless this is in part explained by a lack of interest in the tests or a failure to do well under experimental conditions.

In this country, the National Institute of Industrial Psychology has devised a series of tests for dress-making, which are being successfully applied to the selection of apprentices in one of the largest firms in London. Ten tests are applied simultaneously to a group of 24 girls, taking 55 minutes for this application. They include speed tests in knotting, threading and pricking, tests for good quality of work in the perception of parallel lines, bisecting lines, co-ordinating eye with hand movement, in lightness of touch, and tests of observation and memory.

The present value of the science may be judged by the following illustrations. A selection had to be made among apprentice tool-makers and machinists, of those best fitted for a course of intensive training. The foreman ranked these lads twice, first according to his original estimate of their abilities and later according to a final estimate of them after several weeks of close intimacy during the period of their training. Meanwhile Link applied to the chosen apprentices a series of three tests,—(1) the 'cube' test, in which a large cube had to be built up as quickly as possible from a number of smaller cube-bricks, one or more sides of which were painted in a given colour, so that all four sides of the larger cube were so coloured. (2) The Stenquist test, in which the time was recorded for assembling a series of simple mechanisms, such as a lock, a bell, etc.; a 'form-board' test, in which wooden pieces of different shape had to be fitted as quickly as possible into a board from which gaps of exactly corresponding size had been removed. Now the combined ranking obtained from these tests corresponded very indifferently with the *original* ranking by the foreman, but it corresponded very closely indeed with the *later* ranking by the foreman after he had had several weeks' experience in instructing his apprentices. The correlation between the tests and the foreman's first ranking was only .28, whereas between the tests and his second ranking it reached .9, perfect correlation being, it will be remembered, unity. Here are individual examples of the discrepancy between the foreman's two rankings and of the successful ranking by the tests.—A pleasant willing youth, first ranked by the foreman as fourth, but later as ninth, came out ninth in the tests; an overgrown, 'slip-shod,' dreamy-looking youth, first ranked by the foreman as tenth, but later as fifth, came out 1st, 2nd and 5th in the three tests, respectively; a third apprentice, ranked first as eighth, later as fourth by the foreman, came out fourth in the tests; yet another apprentice, ranked successively as fifth and twelfth by the foreman, came out eleventh in the tests. It may be argued that this particular foreman happened to be exceptionally ignorant, at the start, of the abilities of the apprentices under his charge; but for my own part I suspect that such ignorance is far from uncommon, and I prefer to stress the great help which can clearly be rendered by systematic tests towards selecting the ablest candidates for a given job.

The National Institute of Industrial Psychology has recently devised a series of engineering vocational tests, which has already been applied in a large firm with the object of determining which of 12 branches of the trade each of 250 apprentices is best-fitted or unfitted to pass through. The series includes tests of general intelligence and of spatial judgment (size and shape), motor ability, manipulation and assembly. In the hands of a trained investigator these tests also serve to estimate certain important traits of character, such as impatience, thoroughness, systematic methods of work, etc. Questions bearing on the home and school life and the interests and experience of the apprentice are also asked. Other engineering firms are introducing these tests, realising the saving in time and the gain in efficiency that result from their use.

In his research, for the Industrial Fatigue Research Board, into the qualities and tests required for compositors, Muscio obtained co-efficients of .71 and .80 respectively in the correlation between the ranking by ten tests and by the management in two printing establishments. The tests he employed were—(1) a 'cancellation' test, involving attention, fatigue and speed of action, at which the compositor was engaged for two minutes in cancelling every successive *e* in pages of meaningless French matter submitted to him; (2) a 'substitution' test involving, in addition, memory, in which different numbers had to be pencilled within a series of different geometrical figures according to instructions given at the top of the page submitted to him, *e.g.*, within every circle the number 1 had to be placed, within every triangle the number 2, within every star the number 3, and so on; (3) a 'directions' test of general intelligence, in which the subject had successively to carry out as many different instructions as possible within a given time; (4) a 'match-board' test of dexterity, comprising two tests each lasting 30", the board being placed in the first at arm's length, in the second much closer to the body, and the subject having to insert into the holes on the board as many matches as possible within the time given. Owing to difficulties in scoring, Muscio had to omit a valuable form board test, in which wedge-shaped blocks, resembling the 'quoins' used by compositors to fill spaces in the compositors' 'case,' had to be inserted into a board from which spaces of corresponding size and form had been cut. Muscio determined by the method of partial correlation the extent to which these different tests involved the same capacities, calculating the correlations between the tests themselves as well as between each test and the composing efficiency. He was thus able to weight the importance of the various tests and to reach the already-mentioned results, which are indeed remarkable seeing that composing efficiency, *i.e.*, the ranking by the management, depends also on such here untested factors as trade knowledge, honesty, duty, interest, ambition, etc.

We have yet to discover the relative values of the three methods of procedure in vocational testing,—by sample tests, by analogous tests, and by tests for specific abilities determined by analysis of the occupation. In regard to tests for motor abilities we have evidence of very low correlation between them, whereas the tests for general intelligence correlate highly with one another. It is doubtless a useful hypothesis to assume that there are a few general abilities, several group abilities, and many specific abilities; but their nature and their number we have yet to ascertain. It is more certain that in many individuals at school-leaving age, those abilities have not become fully developed or completely stabilised, and that consequently provision for vocational guidance and the examinations devised for this purpose need to be continued after the boy or girl has entered on his career. We also need further knowledge as to the influence which practice at this occupation may have on success at the tests devised to estimate his abilities in that direction. But although vocational psychology is so young a science, it is already capable of yielding information fuller and more precise than can be reached by the older unsystematic methods of procedure. Further progress in vocational psychology is only possible by experience, as in surgery or medicine. Just as the surgery of to-day is far in advance of that of 200 years ago, and is far behind that of 200 years hence, and just as that advance has only been possible by experience, so vocational guidance and selection must depend for their future on the encouragement and opportunities offered for putting their principles into actual practice.

DISCUSSION.

THE CHAIRMAN, in opening the discussion, said Dr. Myers had introduced the audience to a very vast subject in a very interesting way. It was something like 40 years after the teachers had gone into the schools in a public way that the doctors went there. He did not think it would be another 40 years before the psychologist went after the doctor into the schools. Just as every child now underwent a medical inspection in the school, so in the future, probably at the end of his school career, every child would have to submit to an examination by a psychologist. There would be a good deal of trouble in England before that became compulsory, because while Earl Grey had got on the country's nerves occasionally, by depicting the terrors of the next war, those who had followed the tests and the diagrams of the author that evening must have begun to think of the horrors of industrial peace. For his own part he was perfectly happy in having finished his career before he had had to undergo tests of that kind!

It was interesting to think what the science might lead to, when experience was sufficient, compared with the present practice. The practice had been modified in recent years, but speaking generally, it still consisted very largely of throwing every year out of the elementary schools half a million of children on to the markets. These children had to fit themselves in to whatever posts were available. What it would be desirable to see some day was a high correlation between the posts which were available and the children who were fitting themselves into them.

His own interest in the question was due to the fact that it was one section of the problem of what, to him, was the most interesting question of the present day, namely, that of the adolescent. The paper put forward one phase of dealing with the adolescent—giving him expert advice as to the kind of employment for which he was best fitted. It would be found, of course, that just as men hitherto had defied Nature which had dealt unkindly with them, and had overcome all the physical handicaps which Nature had given them, so in the future men would be found who would defy the psychologist, and who, years after they had been rejected by the psychologist for a given post, would become Prime Minister or head of a great line of steamships, despite the fact that they had been turned down by the psychologist at a given stage because they had not a certain class of ability. There would be those exceptional cases, but he thought there was now clear evidence that the author and his colleagues had got on a line which would become common practice before very many years were over.

Experience up to the present had carried the investigators in the subject only a certain distance. There might be more than just the ignorance of that foreman to which the author had referred. The failing of that foreman might have been due to the fact that there were certain people who could become more expert at a job after a little experience than others who were successful at the beginning, on account of the fact that they had character. They had such a character that they would succeed in anything, and it was possible that the foreman in question had not realised that at first, but had seen it afterwards when he had had five or six weeks' experience of his particular apprentices. There were also certain racial characteristics which had to be taken into account. There was the quick wit and nimbleness of the Irish boy. He had seen the Irish boy at work, and had compared him with the slow but long movement of the Aberdeen boy, out of whom at 14 years of age it was extremely difficult to get anything, but who had the stuff in him all the same, and who would show it later on in life. Things like that could not be measured perhaps in the early stages.

It was very difficult for those who were not engaged in applying the tests and working on them day after day to offer any criticism. One could only talk in the most general way about such a new science, and discuss with some of the investigators particular tests; but the author had said one thing which no doubt would be very pleasing to some adults, namely, that too high an intelligence often led to as much unhappiness as too low an intelligence. Those who prided themselves on their intelligence might be gratified to reflect that if they were unhappy in their job this might be due to their having too high an intelligence!

In London for a long time past there had been in the schools what was called a conference; that was to say, a month or so before a child left school the teacher brought to that conference the child's school record. The parent was there to say what he wanted and what he knew about the child, and other persons were there to give advice. There had not yet been brought into that little group the psychologist, but he would come in some day, and then it would be known much better for what the child was fitted.

The author remarked that "Just as the surgery of to-day is far in advance of 200 years ago, and is far behind that of 200 years hence, so with regard to psychology." That was true, but he hoped the psychologist would not forget that in the process of getting their experience the surgeons had killed a great many people!

Mr. C. G. Watkins said he had come from a truly rural part, *viz.*, Buckinghamshire, to learn something, and he had not been disappointed. How the science was to be applied in rural areas he did not know, but he hoped they would in time follow the good example of London and have their own psychologists.

Mr. Leon Gaster asked whether the tests were applied under ideal conditions or ordinary working conditions, and also what was the best age at which to apply the tests. He had come across cases of children who had not shown of their best up to a certain age, and who up to about 14 or 15 years of age had hated their lessons. Yet those children in after life had turned out to be quite successful.

Mr. Morley Dainow remarked that he highly appreciated Dr. Myers' paper, but as the title of it was "The Use of Vocational Tests in the Selection of a Vocation," he would like to be permitted to describe some other work which was being done in this country. He noticed there was a tendency on the part both of the Assistant Director of the National Institute and of the Director himself to refer only to work that was being done on the subject by the National Institute; but work on the subject had been done, and was being done, in this country on a very important scale by independent psychologists. In 1920 he himself as a psychologist had devoted himself to certain occupations which were beyond the scope of the present paper, for instance, the occupation of salesmanship. He had devised a scheme for Selfridge and Company, which consisted of a series of tests, some not unlike the tests which the author had described, and others, new ones, and only the other day he had received a letter from the Departmental Head of Selfridge and Company to the effect that, in regard to 50 juniors who had been examined by psychological tests, when they compared the records of anticipation by psychological examination with the records of achievement behind the counter, in the office, or in the workshop, they found a marked similarity between the anticipation of the psychologist and the subsequent achievement of the examinees.

In *The Times* of yesterday the following advertisement had appeared: "Exceptionally able man, 35-40, required immediately, experienced in textiles retail distribution, possessing judgment and organising ability; salary up to £2,000. Selection based on psychological tests." That was the first occasion on which any great employer of labour in this country had come to a psychologist in order to be able to find a man who possessed real leadership. Dr. Myers' paper might be described as vocational selection for the workers, for the masses; but there was needed, even more importantly, vocational selection for the leaders, for the classes. Most of the tests which the author had submitted had been tests much more of the mental than of any other side; but there were at least three other sides besides mental, namely, disposition, character and personality. Again, most of the tests put forward by the author that night had been tests for technical work, but there were at least three other kinds of work, namely, administrative, professional and commercial. He suggested, therefore, that the Director of the National Institute of Industrial Psychology should pay some attention to the work which was being done by other psychologists, to the work which was being recognised by heads of commercial and industrial concerns, and to the work which was being applied practically, and which was not merely in the theoretical stage.

Mr. T. Ll. Humberstone said that he was glad the author had referred to the value of the interview pure and simple as a test for efficiency. At the present time the boy candidates for the navy were being selected almost entirely by interview, and he had always argued that that was a defective method. During the war he had been concerned with the selection of candidates for commissions in the army, and he had noticed one thing which many people who were concerned in the same work had noticed also, viz., that some of those selected who did not appear to show evidence of those high qualities of leadership and personality which were so essential for officers of the Army, often showed marvellous and extraordinary bravery and attained high distinction in the war.

One difficulty he saw with regard to the subject matter of the paper was that selection was made at a point of time, and one could not tell what the efficiency would be in ten or twenty years' time.

Another point was whether there was any possibility of forestalling the "crammer." If psychological tests were to be employed as a method of selection, boys and girls would be crammed for them just as they were crammed for examinations.

A further point was that the tests gave the state of efficiency under normal conditions, but not the efficiency in an emergency. One wanted the man who would pull the right lever when the catastrophe was on him, and not merely the man who would pull the right lever when there was plenty of time to think about it.

In all psychological tests it seemed to him the margin of error should be recognised. It ought to be admitted frankly that it was impossible to pick the most efficient. One might pick two, three or four individuals and say that probably the most efficient of the larger group was among those three or four. Perfect selection could not be obtained by any such methods as psychological tests or examination tests.

Mr. P. Abbott said it had been his lot to apply a great many psychological tests, and the one feature in which he thought that at present they failed was that they did not bring out sufficiently strongly those traits of character which were so very important in after life. He had applied the intelligence tests on boys in various ways, and had made selections in consequence of them, but afterwards he had been disappointed in a great many cases, because there was not present in those boys the character necessary to give full effect to the intelligence which had been evidenced in the tests. The author had provided one method of getting over that difficulty, namely, by the interview, but he had added that the interview, if it was to be successful, should be conducted upon scientific lines. Personally he suggested, however, that the ordinary individual at the present time did not know how to conduct an interview scientifically. No doubt the author would answer, "Bring in a psychologist to the interview," but that could not be done on all occasions, and one had to rely upon oneself in many instances to take the part of the interviewer. He therefore suggested that the psychologist should state how an interview should be scientifically carried out.

Mr. R. à-Ababrelton said that there had been for 50 years a class of people who professed to be able to state what an individual was most fitted for, namely, the phrenologists. After all, boys and girls' heads were things more fixed than those things which had been subjected to the author's tests, and the author himself had admitted that there were many cases where the actual results had not borne out the tests.

Mr. Robert Stelling said the subject was of real importance at the present time when we were doing all we could in this country to revive industry and commerce, which was in so deplorable a condition. One thing he felt nervous about in dealing with the question of vocational selection and vocational guidance (although he yielded to no one in his appreciation of its importance as a phase of the science of management) was the premature introduction of vocational selection to specific trades. There was an enormous waste through boys drifting in to the wrong class of occupation, but the trade unions were saying, "Are you going to use these tests to keep people out of our industry? If you are we are going to have nothing to do with it." The answer was, "No; we are trying to fit people to the trades." But he was afraid there was a long way to go yet before the trade unions could be convinced that that was the purpose of the tests.

Another important point was that the conditions in our industries to-day were not standardised. The methods certainly were not standardised, and particularly he would refer to the working conditions. He had in mind the case of a skilled turner who worked for many years under a gallery, and whose only source of illumination was a small gas jet. The man had been working on a second-hand lathe for seven years. The works were then suddenly moved into a large modern shop with perfect lighting, and the man was put on to a lathe right out in the open. The result was that he could not work under those conditions, and went back again to a little shop in a back street, where the conditions were more like what he had always been used to. That showed the necessity for standardising methods and for standardising working conditions. He ventured to suggest that if much was going to be done in the way of useful advice to the youth about to enter upon his life's work in a trade, the conditions of that trade must first of all be studied and analysed and be brought as near perfection and simplicity as possible. Recently a firm in the north of England had been making very elaborate changes and investigations into certain of their methods. As a result of those changes they had been able, with greater comfort to the workers, to increase the output of the department by something like 55 per cent. The extraordinary thing, from the point of view of the matter which was being discussed that night, was that, whereas the skilled workers did not make so tremendous a headway, their wages only going up in fact from 40/- to 45/-, the principal increase of output was among the lesser skilled workers, who had been earning only 30/- or 32/-, and the average wage had gone up in that department from 34/- to 42/- during that period. That seemed to show that if the methods were standardised the work was made open to a far greater number of people, and far more people were able to enjoy the work, to do good work, and to earn good money. He suggested, therefore, that the National Institute should take every opportunity possible for collaborating with industrialists, and particularly that new branch of industry, the industrial engineer, in order to ascertain what were the best ways in which the job could be standardised and analysed, so that they could combine to find the happiest and most suitable work for our youth entering industry to-day.

Mr. G. Harrison said Great Britain was an industrial country. Many thought that it was very much over-industrialised. Consequently the great bulk of the children leaving the elementary schools were fated to take part in monotonous industrial work, whether they liked it or not, and whether they were fitted for it or not. He desired to ask the author whether he had found in the course of his tests that there was any proportion of human beings worth speaking of who were really fitted to pursue, for the course of their lives, a monotonous task of that kind. It had been suggested that the author had not laid any particular stress upon character, and that his tests were merely intelligence tests. He would like to submit, that even from the point of view of an intelligence test, a test of the capacity of a child or a man to go through a monotonous task was not really an intelligence test, and that if it was found that there was a sort of rebellion or resentment against pursuing such a thing, that would be an indication not of a bad character, but of an exceptionally good one. What the psychologist was after in his tests was to try to make human beings fit into a particular system, and personally he doubted very much whether the psychologist would be able to do it.

Miss S. D. Lowe asked what was the best stage of adolescence at which to apply the tests. She happened to be closely connected with juvenile employment, and found that a tremendous development or deterioration of character, as the case might be, among adolescents occurred during the time just after they left school, and were freed from the discipline of school life. Character developed or deteriorated rapidly between the ages of 14 and 15. Therefore, would the author state whether the test should be applied just before the children left school, when they were still under discipline, or should it be applied after they had left school, say, at the age of 15, or should it be applied at both periods in order to form a correct opinion?

Mr. J. F. Butterworth thought the time was not far distant when there would be established in this country, in all the big cities, departments which would be able to furnish psychologists and physiologists to test children for their fitness for work, just as at the present time doctors tested them for their health. The question of psychology undoubtedly was one of the most important features in industry to-day, and he was sorry to say that up to the present time this country had perhaps been the most backward of the big countries in taking it up. Many years ago he had had a friend who had been a psychologist without knowing it. His friend had employed at various times in America over ten thousand workers, and in a country such as America, the most polyglot nation in the world, he very quickly found that if he put his men together in huge gangs, he got merely average results, but that when he divided them up into gangs of Irishmen, Scotsmen, Hungarians, Italians, Germans and Englishmen, he was very easily able to set up a fierce competition between the gangs. His friend used to put up a score board saying what the output of each gang was, and directly the excitable Irishmen saw their figure was being exceeded by another gang, they went to work to beat it. The result was that his friend obtained results which were absolutely marvellous: he had undoubtedly applied his psychology in a practical manner. His friend had also very quickly found that when he had been commissioned to build a Wesleyan Chapel, he did not get the best results from Roman Catholic workmen, or that if he had to build a saloon, he did not get the best results from teetotalers. That was a practical application of psychology.

The Author, in reply, said it was not the psychologist's object, as a result of vocational guidance, to force anyone to go into a particular occupation. The psychologist here merely advised. The ideal of vocational guidance was to get the subject to believe that it was his own decision. That could be done by successful advisers, and in that way the best results were obtained.

Mr. Gaster and Miss Lowe had both asked the very difficult question, namely, at what age the tests should be applied. It had to be remembered that the tests were being used as a supplement to the interview, so that it was extremely difficult to answer the question. There had been too much supposition that night that in the tests there was something absolutely new—a revolutionary thing which was going to alter the whole course of the child's existence. What he desired the audience to bear in mind was that he was urging the tests as something supplementary to the interview. The interview must always be there, so that the question as to when the tests should be applied was like asking, when should the child be advised as to what he should go in for? That must depend on a vast number of things.

With regard to Mr. Gaster's question as to whether the tests were applied under ideal conditions or working conditions, that varied a very great deal.

Mr. Dainow had alluded to the question of salesmanship. He was glad to hear that Mr. Dainow had been so successful. He only wished he had known about it at the time when he had been preparing the paper. All he had made use of was, so far as possible, the data in this country and abroad which had appeared in print.

He had been interested in Mr. Humberstone's remarks, first with regard to cramming. That had always been urged against the intelligence tests, but it did not in practice appear to be a very important objection. He himself had gone through the intelligence tests some little time ago, after having had a general knowledge of their nature, and he had been almost as flustered as he would have been if he had never known anything about them.

Mr. Abbott had said that the tests did not bring out character enough. They were not devised for that purpose; as he had stated before, they were merely a supplement to the interview. If the help of the psychologist was asked so that the interview could be conducted in a more scientific manner, he felt that a great deal could be done in that direction.

Mr. Stelling had stated that the trade unions were likely to be against vocational guidance and selection. Personally he had had a good many talks with trade unionists and all sorts of workers, and he had found that the problem of vocational psychology was one in which they were most interested. He had never received any unfavourable comment about it from that class of people. Its object was to get the best people in those jobs for which they were best suited, and to save them from having a wrong job. In Berlin he had been informed that the Engineers' Union had gone so far as to support the Charlottenburg Laboratory financially, in order that they might not have "duds" getting into their Union. He could assure Mr. Stelling that, so far as his experience went, there was not likely to be any opposition from the trade unions.

With regard to another speaker's remarks, the Institute had also found that, with the improvement of conditions, it was the least expert workers who were most affected. It took a very great deal to improve a really expert person a little more.

Mr. Harrison had asked a very interesting question with regard to the fitness of people for monotonous tasks. There was a good deal of work going on now in that particular subject, some of which had been published in the Institute's *Journal*, and some of which had been carried out partly by the Fatigue Research Board.

Votes of thanks to the Author and Chairman concluded the meeting.

OBITUARY.

Paul Gregory Melitus, C.S.I., C.I.E.—Mr. Melitus, who, as a member of the Indian Civil Service, had a long and successful career in Bengal and Assam, died on February 23rd. Born in 1858, he was educated at Marlborough and Balliol College, Oxford. Having passed the I.C.S. competitive examination he went to India in 1880, and became an Assistant Magistrate and Collector in Bengal. From 1886 to 1891 he filled respectively the offices of Assistant and Deputy Commissioner, Assistant Secretary to the Chief Commissioner of Assam, and acting Postmaster-General of Bengal. He was then appointed Under-Secretary Home Department, Government of India. Subsequently he was Secretary to the Chief Commissioner of Assam, and later Judge and Commissioner Assam Valley Districts. In 1905 he was chosen for a seat on the Board of Revenue, Eastern Bengal and Assam, afterwards becoming its First Member. His last post in India was that of Commissioner in Bengal, and he retired in 1913. He was made a Companion of the Order of the Indian Empire in 1894, and a Companion of the Star of India in 1912. He had been a Fellow of the Royal Society of Arts since 1906.

CORRESPONDENCE.

THE TREATMENT OF THE DEATH-WATCH BEETLE.

I regret I was unable to attend the reading of this paper by Professor H. Maxwell-Lefroy, to make the following suggestion.

The beetle breathes and, therefore, can be, as I have verified by experiment, exterminated by periodical "gas attacks." The labour and cost of this is nothing like so heavy as the inefficient use, when practicable, of fluids.

A. E. PARNACOTT,
M.I.A.E.

RECENT DEVELOPMENTS IN NAVAL ARCHITECTURE.

Sir Eustace W. H. Tennyson-D'Eyncourt, Director of Naval Construction and Chief Technical Adviser to the Admiralty, recently delivered the Watt anniversary lecture before the Greenock Philosophical Society, upon this subject.

The developments in naval architecture down to the present time, he said, could only be appreciated properly if one considered for a moment the conditions under which ships were designed and constructed before the days of James Watt and the steam engine. British warships were standardized by the Admiralty in their principal dimensions, and consequently could not be departed from. All the useful knowledge was kept secret; and as a result there had been little real progress in the science of naval architecture since the days of Queen Elizabeth. The opening of the first English school of naval architecture at Portsmouth in 1811 was the first real step taken whereby the study of the science was inaugurated and encouraged. Referring to the introduction and utilization of the mine, the torpedo, the aeroplane, the use of wireless telegraphy, and all other adjuncts which have been developed, the naval advances of the nineteenth century had yet to be determined by actual warfare, and the Great War was the acid test of all the modifications in naval design.

The aeroplane must play an enormously important *role* in any future war; the mine was used with effectiveness by both sides in the recent war; the torpedo was made the most dreaded weapon on that occasion; and the development and use of the submarine was one of the most unexpected features, and necessitated the design and construction of vessels for the purpose of hunting and destroying this new form of torpedo craft, and developing devices for detecting the presence of the submarines and to accomplish their destruction. In naval architecture itself there had been striking improvements in the designs of ships and their propulsive qualities; and research work had enabled the naval architect to take full advantage of the improvements in materials which had been offered him by the metallurgist and the steelmakers. At the present time, armour capable of withstanding the attack of modern shells could be produced of half the thickness and weight which was required 40 years ago to resist the much inferior attack of that date. Within the last year or two marked improvements had been made in the qualities of structural steel; and recent processes would enable appreciable reductions to be made in the weight of the structure of new ships. The improvement which had taken place in the various types of engines had been steadily maintained by the introduction of the steam turbine, the utility and economy of which had been further developed by the introduction of gearing which had had marked results in improving the propulsive co-efficient of vessels.

Concurrently with an improvement in the engines there had been introduced more economical methods of raising steam, and fuel economy had been improved by the various developments in machinery and boilers, and assisted by the use of the geared turbine. A striking advance in this direction had resulted from the introduction of the internal combustion engine, but it had been found so far. impracticable to introduce this type into warships for propelling purposes. These engines were installed for driving dynamos, with the consequent advantage that steam need not be raised when in harbour. The introduction of oil fuel for steam raising had had a most marked effect on the design and construction of ships during the last ten years. Its adoption contributed in no small degree to the successful operation of the Fleet during the war. Without its use we could not have approached the power required for the high speeds of our torpedo boat destroyers and light cruisers. Our warships had demanded larger complements, both of officers and men, by the introduction of these and other appliances, especially wireless telegraphy. There was a great increase in the number of vessels constructed for the Navy during the war, the tonnage being 2,000,000.

The effect of the war upon designs had been great, and had brought about striking developments. The ever-increasing size was, of course, remarkable, and the steady increase of the use of internal combustion engines was a great feature of recent developments. That this would continue there was not the least doubt. In concluding, the speaker said that the present position as regarded the provision of facilities for obtaining the highest training for naval architects and marine engineers might generally be regarded as very satisfactory, and the continued development of naval architecture was thereby assured.

PIG BREEDING IN SCOTLAND IN 1923.

There has been continuous progress in pig breeding in Scotland during the year 1923, notwithstanding the fact that there have been many disappointments for the pig-breeder. It is satisfactory, however, to be able to put on record that the pig population in Scotland as at June 4, 1923, showed an increase of 35,143, or 23.29 per cent. over the previous year. The total population of pigs at that time was 186,027. This figure, although a satisfactory one from the point of view of Scotland, compares very badly with the figures as applied to other parts of the world, the total pig population of Great Britain being 2¼ millions, and if the whole of Ireland is included, 3¼ millions, out of a total pig population in Europe of some 55 millions.

The increase in the pig population of Scotland is highly satisfactory, as it would seem to indicate that the business of swine husbandry has now become an essential part of agriculture; and, indeed, this fact is brought out from an examination of the details giving the numbers of pigs bred in each Scottish county. The figures show, amongst other things, that the ancient prejudice against pig breeding in the Scottish Highlands has disappeared. There was a time when one of the names which the Gaelic-speaking population of Scotland gave to the devil was "The Big Black Pig;" but at present there are something like 100 herds of large black pigs in Scotland, pretty evenly distributed all over the country, and some of the more notable of these are situated in the Western Highlands.

Unfortunately, the number of breeds of pigs which are recognised in Great Britain as pure breeds is still increasing, and it looks as if the number would increase to fifteen pure breeds in all. This multiplying of the breeds is not regarded favourably by the bacon curer, as it in nowise contributes to the production of the bacon pig, which, after all, is the natural corollary of pig breeding. The cross-bred pig, it would seem, is preferred by the bacon curers before the pure-bred animal. But it is quite a mistake to suppose that a cross-bred pig is any better than a bacon pig derived from a pure breed. It is altogether a question of selection and feeding.

The Scottish pig breeders have pretty generally come to the conclusion that the cross-bred pig seems to mature earlier, and undoubtedly commands a readier sale for bacon purposes than the pure-bred animal. In corroboration of this view, it may be mentioned that, at the last Smithfield Show in London, the championship for the pig best suited for the manufacture of bacon was awarded to a cross between a large white boar and a large black sow. At the age of 5 months and 3 weeks this particular animal scaled 2 cwt. 5lb., live weight, without being in the least degree too fat for bacon curing purposes.

A good many Scottish breeders are at present trying to cross with the large black sire and the large white sow. Others, again, are trying the large black sire on the middle white sow. The results in either cases have been quite satisfactory, as have many other crosses in which the large black sire is being used.

The sire is undoubtedly pre-potent in the breeding of pigs, and, for that reason, it is always desirable to have a pure-bred sire where cross-bred pigs are produced. Experiments have shown that the use of a pure-bred boar has, by comparison, shown an increase in pig production of 40 per cent. over the common nondescript boar. This, then, must be one of the principal objects of the pedigree pig breeder—namely, to supply pure-bred sires of whatever breed may be particularly fancied.

Pig breeders in Scotland have had some serious misfortunes during 1923. First of all came the foot-and-mouth disease, which has practically stopped all movement of swine throughout the country; and the great exhibition of pigs which was to have taken place at Glasgow Dairy Show was prohibited. Similarly, and for the same reason, the Edinburgh Fat Stock Show did not take place, and the entry there would have been a record. Then, during the latter part of last year, there was continuous rain; and, latterly, extremely cold and wintry weather, so that the outdoor system of raising pigs has to be carried on under the most trying weather conditions. Farrowing in winter in Scotland, at all times, is a risky business; but, during the later months of the year it was necessary to provide heat in the farrowing styes, as otherwise the piglets would have received a setback from which they would be unlikely to recover.

LOUDON M. DOUGLAS.

COTTON AND RUBBER IN PERU.

The principal products of Peru, writes the British Vice-Consul at Callao, are cotton, sugar, wool, hides and skins, rubber, rice and coca.

Cotton.—The total production of cotton in Peru in 1921 was 40,769 metric tons and in 1922 probably more than 42,000. The year 1923 may show an increased production of perhaps 10 per cent. over the preceding year. The production of Tangüis (named after the discoverer of this highly successful blend of rough and smooth cotton) reached about 40 per cent. of the total, and as a good price was obtained, it has led to a more extended sowing of this class of cotton. Its woolly nature lends itself to admixture with wool in the manufacture of woollen goods. Last year over 90 per cent. of the Tangüis went to Liverpool. Of the export of 39,952 metric tons (gross) in 1922, England took over 34,000 tons and the United States nearly 5,000 tons. In the first half of 1923, 8,890 tons were exported, against 13,601 tons in the same period of 1922.

In the regions of the upper reaches of the Amazon, the crop in 1922, although a disappointing one owing to the destruction done in the cotton-growing areas between the Huallaga and Ucayali rivers during the revolution in 1921, showed an increased return on the previous year. In 1922 the exports from this region amounted to 1030 metric tons, all rough and semi-rough qualities. Much larger areas were put under cotton in 1923.

Rubber.—Wild rubber abounds in the Amazon regions, its original home, and whence the Far Eastern product was transplanted. The export, which had been only 137 tons in 1921 (the official figure, which probably did not include December), increased to 602 tons net in 1922. An examination of the possibilities of creating in the Amazon district an independent source of supply of plantation rubber for American consumption is about to be made by an American Commission. The sum of half a million dollars has been voted in the U.S.A. for investigation in the Philippines and Central and South American States, and the latter are vying with each other in offering inducements. The restriction on production—under the Stevenson arrangement—of Eastern rubber has led the United States, which require over 70 per cent. of the world's output, to contemplate a time when the supply from the present sources may not be sufficient to meet their needs. There are, it is stated, many millions of trees in the Peruvian rubber forests, but the wild rubber cannot be collected profitably, and the trees would be cleared for the proposed plantation. As it would require some seven years before any rubber could be produced from the latter, it is thought that the proposed railway from the Marañon to the Pacific might be available. In this case the product from the eastern side of the Andes could be landed in New York *via* the Pacific coast and Panama Canal in a fortnight. The alternative—and present—means of transport is *via* the Amazon rivers for nearly three thousand miles to the Atlantic. The Peruvian Government, eager to attract a new industry, offers the Commission very large tracts of land free, together with many other advantages, such as duty free imports of materials, etc. It is considered that the lack of a supply of labour in these regions, necessitating contracting labour from abroad, will militate against the success of this scheme.

GENERAL NOTE.

Sumatra Rubber.—Attention has been called in *Tropical Agriculture* to the amount of native-owned rubber in Sumatra—an island which is more than twice the size of British Malaya, to the south-west of which, in the Indian Ocean it is closely situated. It is estimated that the natives own some 50 million trees, which, under good management, should yield 80,000 tons of rubber per annum—an amount quite capable of influencing the world's market price. This might be important at times when attempts are made to raise the price of rubber by restriction of Company operations. Influence of this kind was actually experienced in the initial stages of restriction in the Federated Malay States in 1920. It is, therefore, important that statistical data should be obtained and studied in respect of native cultivations. Regarding the quality of Sumatra native rubber it would appear that for the most part it is equal to off-quality smoked sheet.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

March 26.—**Neal Green**, "The Fishing Industry and its By-Products." **Professor E. W. MacBride**, D.Sc., F.R.S., will preside.

April 2.—**Sir Lynden Macassey**, K.B.E., "London Traffic." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

April 9.—**Frank Hope-Jones**, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." **Professor C. Vernon Boys**, F.R.S., will preside.

April 30.—**Brigadier-General Sir Henry Maybury**, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "The London Dock District and its Roads."

May 5 (Monday).—**T. Thorne Baker**, "Photography in Industry, Science and Medicine."

May 7.—**J. Robinson**, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation." **Admiral of the Fleet Sir Henry Jackson**, G.C.B., K.C.V.O., F.R.S., will preside.

May 14.—

May 21.—**Professor C. Vernon Boys**, F.R.S., "Calorimetry." (Trueman Wood Lecture.)

May 28.—**Mrs. Arthur McGrath** (Rosita Forbes), "The Position of the Arabs in Art and Literature." **Lord Askwith**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Indian Section.

Friday afternoons, at 4.30 o'clock:—

May 2.—**Jocelyn F. Thorpe**, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced:—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

Dominions and Colonies Section.

Monday or Tuesday afternoons, at 4.30 o'clock:—

May 27.—**C. Gilbert Cullis**, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

June 16.—C. V. Corless, M.Sc., LL.D., "The Mineral Resources of Canada: The Pre-Cambrian Area."

Cobb Lectures.

Monday evenings, at 8 o'clock:—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

Syllabus.

Lecture I: March 24.—Colloids. Suspensoids and emulsoids. Gelatin as an emulsoid and amphoteric colloid. Isoelectric point and properties of isoelectric gelatin. Combination of gelatin with silver nitrate and other salts.

Effect of gelatin on reactions involved in making a photographic emulsion. Ripening of silver halides; effect of various reagents. Physical processes involved in development. Development in hot climates and prevention of swelling. Reticulation.

LECTURE II: MARCH 31.—Hardening of gelatin. Ordinary fixing and acid fixing baths.

Medium free silver halide. Gelatine as a retarder of development. Black and grey silver images. Coloured silver images and silver colour scale. Production of coloured images Gelatine as a sensitiser.

LECTURE III: APRIL 1.—Photohalides and the visible image. Sensitising action of silver ions. Latent image. Duplication of light action by chemical agents. Silver halide grain as the unit. Sensitive centres on the grains. Nucleus exposure. Nature of the sensitive centres.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, MARCH 24 ... Geographical Society, 135, New Bond Street, W., 8.30 p.m. Dr. L. Koch, "Northward of Greenland."

Mechanical Engineers, Institution of, Storey's Gate, S.W., 7 p.m. (Graduates' Section). Informal Discussion on "Failure in Metals."

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Mr. W. E. Leslie, "Telepathy."

Architectural Association, 34, Bedford-square, W.C., 7.30 p.m. Miss M. Jourdain, "The Architect as Designer of Furniture."

University of London, at King's College, Strand, W.C., 5.30 p.m. Dr. R. W. Seton-Watson, "A Survey of Bohemian History." (Lecture VIII.)

5.30 p.m. Senhor Rangal de Castro, "The Civilisation of Brazil." (Lecture II.)

TUESDAY, MARCH 25 ... Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 6.30 p.m. Mr. H. S. Rowell, "The Balancing of Automobile Engines."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. J. Ward, "Some Notes on the Theory of Lubrication with particular application to the Mitchell Thrust."

Colonial Institute, Hotel Victoria, Northumberland-avenue, W.C., 4 p.m. Rt. Rev. Bishop G. Jones, "The Nile Route to Uganda."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. J. D. Johnston, "Developments of Pictorial Photography in England and America."

Royal Institution, Albemarle-street, W., 5.15 p.m. Prof. G. Gordon, "Ballads." (Lecture I.)

University of London, at King's College, Strand, W.C., 5.30 p.m. Prof. Smal-Stotsky, "Shevchenko and Modern Ukrainian Literature."

WEDNESDAY, MARCH 26 ... London County Council, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Sir Napier Shaw, "Modern Meteorology." (Lecture IV.)

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5 p.m.

British Academy, at the Royal Society, Burlington House, Piccadilly, W., 5 p.m. Dr. T. Borenius, "English Primitives."

Oriental Studies, School of, London Institution, Finsbury Circus, E.C., 5 p.m. Miss E. D. Edwards, "Manchuria."

United Service Institution, Whitehall, S.W., 3 p.m. Rear-Admiral H. L. Mawbey, "The Past and Future of the Royal Indian Marine."

Glass-Painters, British Society of, at the Art Workers' Guild, 6, Queen Square, W.C., 5.30 p.m. Dr. T. M. Legge, "Specimens of 15th Century Stained Glass"; Mr. E. S. Eden, "Ancient Stained Glass in London."

University of London, University College, Gower-street, W.C., 6 p.m. Prof. K. Pearson, "The Current Work of the Biometric and Eugenics Laboratories." (Lecture VII.)

5.30 p.m. Dr. W. Seton, "The relations between Scotland and England in the Sixteenth Century." (Lecture V.)

At the Royal College of Music, Prince Consort Road, S.W., 5 p.m. Sir Henry Hadow, "English Composers of the Tudor Period." (Lecture II.)

Microscopical Society, 20, Hanover Square, W., 8 p.m. 1, Mr. G. O. Searle, "Methods of Mass Production in Sectioning Flax Stems." 2, Dr. H. Wrighton, "Microscopical Metallurgy." 3, Demonstration of "Technical Microscopy." 4, Mr. J. E. Barnard, "The Setting up and Adjustment of a Microscope."

Japan Society, 22, Russell Square, W.C. Mr. Hugh Byas, "The Press in Japan To-Day."

THURSDAY, MARCH 27 ... Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. Lieut.-Colonel H. E. O'Brien, "The Future of Main Line Electrification of British Railways."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Sir George Paish, "Trade Depression and its Remedy."

Auctioneers and Estate Agents Institute, 34, Russell Square, W.C., 7.30 p.m. (Junior Members' Meeting). Mr. H. A. Robertson, "Some Notes on the Assessment of Delapidations."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. D. S. Watson, "Evolution To-day." (Lecture II.)

Mechanical Engineers, Institution of, The University, Edmund Street, Birmingham (Midland Section), 7.30 p.m. Mr. O. H. Petford, "Economic Considerations on the Generation of Steam for Power Purposes."

University of London, King's College, Strand, W.C., 5.30 p.m. Prof. W. W. Buckland, "The Classic Roman Law: Recent Investigations." (Lecture II.)

Chemical Society, Burlington House, Piccadilly, W., 4 p.m. Annual General Meeting. Address by the President, Prof. W. P. Wynne.

FRIDAY, MARCH 28 ... Engineering Inspection, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. 1, Annual General Meeting. 2, Mr. H. B. Spencer, "Inspection Clauses in Engineering Specifications."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Joint Meeting with the Institution of Civil Engineers to discuss report on Standard Tests for Hydraulic Power Plants."

Royal Institution, Albemarle Street, W., 9 p.m. Dr. H. Maclean, "Insulin."

Chadwick Lecture, Council Chamber, Old County Hall, Spring Gardens, S.W., 8 p.m. Mr. J. T. Quinton, "The Sanitary Inspector in the Machinery of the Public Health Service."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Capt. A. G. Buckham, "The Way of the Lovely Sky."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Engineers, Junior Institution of, 39, Victoria Street, S.W., 7.30 p.m. Mr. A. J. Simpson, "Wood Wall: its Manufacture and Application."

Chemical Industry, Society of, at the Institution of Civil Engineers, Great George Street, S.W., 6 p.m. Mr. L. Andrews, "Kinetic Electrisation."

(South Wales Section), Technical College, Swansea, 7.15 p.m. Address by Captain H. Vivian.

(Glasgow Section), 39, Elmbank Crescent, Glasgow, 7.15 p.m. Dr. J. A. Cranston, "The Influence on Chemistry of the Recent Knowledge gained from Atomic Structure."

SATURDAY, MARCH 29 ... London County Council, at the Horniman Museum, Forest Hill, S.E., 3.30 p.m. Mr. S. H. Warren, "Prehistoric Man and the 'Land of Lyonesse.'"

Journal of the Royal Society of Arts.

No. 3,723. VOL. LXXII.

FRIDAY, MARCH 28, 1924.

3 MAY 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MARCH 31st, at 8 p.m. (Cobb Lecture.) DR. T. SLATER PRICE, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." (Lecture II.)

WEDNESDAY, APRIL 2nd, at 8 p.m. (Ordinary Meeting.) SIR LYNDEN MACASSEY, K.B.E., LL.D., D.Sc. (Secretary to the Royal Commission on London Traffic, 1903-7), "London Traffic." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

FRIDAY, APRIL 4th, at 4.30 p.m. (Extra Meeting.) GEORGE MACAULAY BOOTH, Director of the Bank of England and of the Booth Steamship Company, Ltd., "The Amazon Valley and its Development." H. E. THE BRAZILIAN AMBASSADOR will preside.

[A collection of specimens illustrating the resources of the Amazon Valley will be on view in the Library from Friday, April 4th, to Thursday, April 18th.]

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

A meeting of the Council was held on Monday, March 10th. Present:—

Lord Askwith, K.C.B., K.C., D.C.L. (in the chair), Lord Bearsted, Mr. C. F. Cross, F.R.S., Sir William H. Davison, K.B.E., D.L., M.P., Mr. Edward Dent, M.A., Rear-Admiral James de Courcy Hamilton, M.V.O., Major Sir Humphrey Leggett, D.S.O., R.E., Dr. William H. Maw, M.Inst.C.E., Mr. John Slater, F.R.I.B.A., Sir George Sutton, Bt., Mr. James Swinburne, F.R.S., Dr. J. Augustus Voelcker, M.A., and Sir Philip Watts, K.C.B., LL.D., F.R.S., with Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

On the motion of Lord Bearsted a vote of condolence and sympathy with Sir Philip Magnus, Bt., on the death of Lady Magnus, was passed.

Lord Askwith was appointed to represent the Society on the occasion of the Jubilee Celebrations of the Physical Society of London on March 20th to 22nd, and at the Kelvin Centenary Celebrations in London on July 10th and 11th next.

Sir Frank Baines, C.V.O., C.B.E., was nominated as the Society's delegate at the conference organised by the British Association for the Advancement of Science to consider further protection of sites of historic interest or of natural beauty against disfigurement or obstruction.

Arrangements for papers and lectures were considered.

Other formal business was transacted.

FIFTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 19th, 1924; LORD CLINTON, Forestry Commissioner, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Agnew, Andrew, C.B.E., London.
Anderson, Percy, M.B.E., Gerrard's Cross, Bucks.
Lundie, John, D.Sc., New York City, U.S.A.
O'Brien, Arthur Matthew, F.C.S., Skewen, Glam.
Parker, Charles, Nottingham.
Summers, Daniel Henry, Portsmouth.
Verma, Banwari Lall, Delhi, India.

The following candidates were duly elected Fellows of the Society:—

Arnold, James Ernest, F.R.G.S., London.
Bethell, Lieut.-Colonel L. A. B., Landi Kotal, N.-W.F. Province, India.
Bhatia, G. R., Dehra Dun, India.
Hall, A. G., Assoc.M.Inst.C.E., Landi Kotal, N.-W.F. Province, India.
Raley, Captain George Giles Emsley, B.A., M.C., Toronto, Canada.
Roberts, Lieut.-Colonel Sir James Reid, C.I.E., F.R.C.S., London.

A paper on "The Forests and Timber Supply of North America" was read by MR. R. L. ROBINSON, Forestry Commissioner.

The paper and discussion will be published in a subsequent number of the *Journal*.

INDIAN SECTION.

Friday, March 21st, 1924; Lord Lamington, G.C.M.G., G.C.I.E., in the Chair.

A paper on "The Progress of Co-operative Banking in India" was read by Mr. Otto Rothfeld, I.C.S.

The paper and discussion will be published in a subsequent number of the *Journal*.

COBB LECTURE.

Monday Evening, March 24th, 1924; Dr. T. Slater Price, Director of Research, British Photographic Research Association, delivered the first lecture of his course on "Certain Fundamental Problems in Photography."

The lectures will be published in the *Journal* during the summer recess.

VISIT TO THE GUILDHALL.

On behalf of the Fellows of the Society and their ladies, the Council have gratefully accepted an invitation from Mr. H. G. Downer, LL.B., a member of the Common Council, to inspect the Guildhall, including the Art Gallery of the Corporation of London, on Thursday, May 8th at 2.30 p.m. Sir Alfred George Temple, F.S.A., will act as escort in the Art Gallery and Mr. Deputy Alderton, C.C., in the Council Chamber, Crypt and other places of interest in the Guildhall.

Fellows desirous of availing themselves of the invitation should inform the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.2., on or before May 3rd, mentioning the number of their party.

Those attending are requested to assemble at the main entrance to the Guildhall in King Street, Cheapside, at 2.30 p.m.

PROCEEDINGS OF THE SOCIETY.

◆

DOMINIONS AND COLONIES SECTION.

Tuesday, March 4th, 1924.

The Rt. Hon. Lord Bearsted in the Chair.

The Chairman said that before he called upon Mr. Cochrane to read the paper he had prepared, he would like to say that Sarawak was a field that inspired enthusiasm because it commemorated those traits which had made England what she was. Sarawak was brought into prominence by Sir James Brooke, a popularly-elected chief, elected by the natives who could not rule themselves, but who knew the great traditions of the British Empire in founding colonies. Therefore, the lines followed in the establishment of Sarawak were very much like those of the old East India Company—private enterprise, and the flag following. The development of the oilfields in Sarawak was another creditable achievement of the same kind. The company who had developed Sarawak was chosen by the late Sir Charles Brooke to do it, because they had a reputation in which he believed. How great the enterprise was the audience would realise as the paper was read. They entered upon it entirely unassisted by any Government and not dependent on any Government either. The result had been one of which the Empire might be proud, and which, if he was not mistaken, would make Sarawak one of the brightest jewels in the crown of the British Empire.

The paper read was:—

EMPIRE OIL: THE PROGRESS OF SARAWAK.

By the Hon. T. G. Cochrane, D.S.O.

On April 11th, 1923, a very interesting paper on "Sarawak, its Resources and Trade," by Mr. E. Parnell, was read before the Society. In this, however, only a brief mention was made of the petroleum industry, and it is the purpose of the present paper to amplify the information then given.

The production of petroleum in Sarawak in 1923 was about 560,000 tons, and though this is not large in comparison with, say, California or Mexico, it has this point of special interest and importance—that it is produced within the Empire. "The Oil Resources of the British Empire" was the subject of a paper read before the Society by Sir John Cadman on June 4th, 1920. In this the production from Sarawak for 1918 was given as 80,000 tons, making it a very bad fifth in the list of producing countries within the Empire. To-day Sarawak can claim to be by no means a bad second—the lead, of course, still being held by the great oilfields of Burma, the work of many years of development.

The presence of oil seepages in the neighbourhood of the Baram and Miri Rivers had been known for many years before any active steps were taken to investigate the possibilities of obtaining a commercial production from them.

A series of more or less active seepages, located a little inland from the original Miri village, were actually exploited in a primitive way by the Miri Malays. The procedure was to dig pits about three feet deep in the zone of seepages. Being in swampy ground these pits filled with water on the surface of which the oil floated. This oil was skimmed off by the natives using gourds or cocoanut shells, and burnt for lighting their huts in very primitive lamps, made from any convenient vessel, such as an empty tin, a small gourd or even a bottle, using a strip of cotton or other cloth to serve as a wick.

The bituminous residue or asphalt which was found at the seepages (the result of evaporation and oxidation) was also used by the natives for caulking their dugouts. Later the use for this purpose of damar, an indigenous resin, and the importation of kerosene oil combined to make the working of these seepages less advantageous, and interest was gradually lost in them.

In the year 1909, however, the Anglo-Saxon Petroleum Company became sufficiently interested in the possibilities of the Miri district to make an application to the Rajah of Sarawak—the late Sir Charles Brooke, G.C.M.G.—for a concession to exploit the oil resources of Sarawak.

The Rajah in due course granted to the company a concession on terms which were fair and satisfactory to both parties. One particular stipulation which the Rajah did make, and one which will commend itself to all subjects of the British Empire, is contained in Clause 14 of the Concession, which reads as follows:—"The Company hereby covenants that during the continuance of the licences hereby granted it will not export any of the said mineral products which can be safely used as liquid fuel, so as to leave a quantity of less than 10,000 tons (English measure) stored in the district aforesaid, and further that such quantity of ten thousand tons of liquid fuel shall be used only for the purpose of supplying the ships of the Navy of Great Britain or any of her Colonies." The only exceptions which have been made in the carrying out of this patriotic wish of the Rajah have been that, for a period during and directly after the War, with the consent of the Rajah and the Admiralty, fuel oil was stored at Singapore instead of at Miri; and that naval vessels of our Allies the Japanese were included in those which could be supplied from that 10,000 tons of Sarawak oil.

As a result of this concession being obtained it was necessary to arrange for a Geological Examination to be carried out. The geologist chosen for this purpose was Dr. J. T. Erb, now a Director of the Anglo-Saxon Petroleum Company.

Between August and December, in the year 1909, Dr. Erb carried out a rapid reconnaissance survey in the northern part of Sarawak, covering some 400-500 miles, and was able to report the existence at Miri of a dome-shaped, unsymmetrical anticline, with a steep Eastern flank and numerous oil shows. He received very cordial assistance from the Sarawak Government officials.

In February, 1910, Dr. Erb returned to Miri, and after further investigation of that area, fixed the location of the first well.

In March, 1910, the first definite steps were taken which laid the foundations for the present successful petroleum industry of Sarawak. Mr. McAlpine, a Canadian, was selected from one of the already established oil fields in the Dutch East Indies to proceed to Miri and ascertain what material, labour and foodstuffs would be required, and what could be obtained locally. It may be mentioned here that Mr. McAlpine is still at Miri, occupying the responsible position of Field Manager, and that much of the success that has been achieved may fairly be attributed to his efforts.

At the time of Mr. McAlpine's first visit the village of Miri, together with that of Pujut, could only muster about 80 able-bodied men and youths. For provisions there were two Chinese stores, whose whole stock consisted of a few tins of bully beef; everything else had to be imported. The Sarawak Government officials who were consulted reported that the coast was unapproachable from September to March on account of the monsoons, and that it was advisable to lay in a stock of provisions to last for at least six months during that period.

Mr. McAlpine returned to Singapore, where 25 Chinese coolies were obtained and a 50-ton lighter was bought. This lighter was packed with stores and towed to Kuching, where a further labour force of 10 Malay carpenters and 20 coolies had been recruited.

At this time there was no regular communication between Kuching and Miri by sea, but it was arranged with the Government that one or other of the old paddle steamers which then ran between Kuching and Limbang should call once a fortnight at Miri on the outward voyage. The lighter was towed from Kuching to Miri by one of these boats, arriving there at the end of April.

There was no accommodation available at Miri, and all hands set to work to build shelters for the Chinese coolies, the Malays being billeted on the natives. It is pleasant to record that these pioneers of a new industry in Sarawak had a most friendly reception from the natives, and were given every help and encouragement by the Sarawak Government officials. The rig irons, boilers, engines and drilling tools were dispatched from the Sanga Sanga field in the Dutch East Indies in charge of Mr. Souter, an English driller, and arrived at Miri early in May.

Great difficulties were encountered in bringing the material ashore; the only landing place was inside the Miri river, and the only means of propulsion for the lighter was by punting it with poles. As the river current was rather strong it was necessary to take the lighter to sea on an ebb tide and bring it back on a rising one. The bar of the river is shallow, has no shelter, and only about a foot of water over it at low water spring tides, so that the operations had to be nicely timed to avoid sticking on the bar with a valuable cargo, at the mercy of any sudden storm that might arise. In spite of these difficulties, however, by August nearly the whole of the drilling material and six months' provisions had been safely landed without any serious mishap.

The site for the first well was located about a mile from the landing place, 260 feet above sea-level. The drilling boiler took 80 men with blocks and tackle three days to haul into position. Drilling commenced on August 10th, the wire line and poles method, which had proved very successful in the Dutch East Indies, being used.

Exactly two months later, on October 10th, oil was struck at a depth of 447 feet, and the well produced 4 tons of water-free oil per day. It was then deepened slightly to 510 feet, from which level it produced 12 tons a day. The arrival of the fortnightly steamer from Kuching was anxiously awaited to enable a cable to be sent to London announcing this favourable result. The weather was stormy and no steamer appeared, so Mr. Souter volunteered to go on foot to Brunei, some 90 miles by the coast route. He arrived in Brunei in four days, whence he took a launch to Labuan Island where there was a cable station, and the good news duly reached London that oil in commercial quantities had been found in Sarawak.

I have devoted some time to describing the initial difficulties which were met with and how they were overcome, and though it may be thought that all thereafter would be plane sailing, it must be remembered that the mere capacity to produce oil is of itself of no value commercially, unless it can at any rate be stored as it is produced, and, still more important, shipped to some market where it can be sold. The progress which was made and the steps which were taken to meet these essential requirements, I now propose to describe. I will commence by giving some details of the extension of the Miri field after the bringing in of the first well.

The success of the first well, of course, necessitated its being shut in until storage could be erected. A second well was commenced in April, 1911. In September, Mr. H. Wyndham Jones, the first General Manager, arrived and took charge of the operations. He remained at Miri until 1920, when he was able to hand over to the present General Manager, Major E. V. Benjamin, M.C., a vastly larger and more important enterprise than he had found nine years previously. The first steel storage tank of 4,500 tons capacity was completed in October and the production for the year was about 260 tons.

In 1912 drilling was continued with only a moderate amount of success, the total production for the year being 5,635 tons. During the year a small distillery was constructed from old steel oil drums, and the crude oil treated to produce a straight run benzine of .760 sp. gr., an intermediate kerosene product and a fuel oil of .900 sp.gr., which was used in a steam launch. The benzine produced was taken over by the Sarawak Government for use locally in street lamps and motor launches. Two further tanks of 4,500 tons capacity each were also completed. By the end of the year the staff comprised 19 Europeans and a native labour force of 424 Malays and Chinese.

During 1913 drilling proceeded energetically, but no very good wells were completed in the Miri field itself. A probable extension of the Miri field to the north, however, had long been recognised, and well No. 8 was located at Pujut, and at a depth of 1,402 feet came in flowing at a rate of 80 to 100 tons a day. The production for the year was 26,067 tons and the staff had increased by the end of the year to 26 Europeans, with 764 natives and Chinese.

On April 18th, 1913, the first shipment of Sarawak oil was made in two lighters, which were towed away from the Miri River. The experiment was also tried later on of mooring a tanker off the Miri River to act as a floating storage tank. This, however, was not altogether a success, as the weather often made it impossible for a tanker to go alongside, and lighters had still to be used.

In 1914 further successful wells were drilled, although none of them were very large producers. The total production for the year was 64,510 tons, and the staff had increased to 29 Europeans with 969 natives and Chinese.

In August of that year the first attempt was made to lay a submarine pipe line through which oil could be pumped to a tanker lying at anchor in deep water. The proposed method was to float the line out in three sections, each about 4,500 feet long. The pipe line was of 6 inches diameter, and the position of the shore end was about 500 yards south of the mouth of the Miri River. Soundings showed that to reach a depth of 24 feet of water a length of about 13,500 feet would be required. It was intended to tow the sections out in succession and couple them together with specially prepared short lengths of pipe as each section left the beach. The only reason for adopting this method of launching in sections rather than towing the whole line out in one piece, as was done with the lines subsequently launched at Lutong (of which a description will be given later), was this: the maximum length of level ground available at the spot selected was 4,500 feet, and thus to reach a depth of 24 feet of water three sections of line, each 4,500 feet long, had to be prepared on separate runways and towed out in succession.

The first two sections were floated out successfully, but whilst the second and third sections were being connected up a sudden squall caused enough sea to get up to break the floating line some 200 feet from the beach. All hope of connecting up the third section was abandoned, and the floats, consisting of 8-gallon drums tied to the pipe at intervals, were cut away and the line allowed to sink to the bottom. The depth of water at the sea end was about 18 feet, which was sufficient for the time being. In spite of trouble with the flexible hoses which frequently broke, 22,755 tons of oil had been loaded into tankers through the line by the end of the year.

At the beginning of 1915, as was to be expected, and indeed down to the end of 1919, operations at Miri were much handicapped by shortage of materials and staff, and to an even greater extent by shortage of shipping and storage.

In October, 1916, a topping plant on the Trumble system was completed on a site about 500 yards south of the Miri river. This had a capacity of 500 tons a day, but in view of the war conditions, was only operated to produce fuel oil and distillate. During the time in which it was in operation in 1916 it produced 10,464 tons of liquid fuel. The existence of the topping plant enabled fuel oil to be produced for the Navy, but this could not, of course, be produced without also producing a distillate, consisting of the lighter fractions for which there was no demand under war conditions. At a time when every tanker was urgently required for the transport of fuel oil or benzine to some theatre of war, it was seldom possible to spare one for the carriage of distillate.

Under these abnormal circumstances an abnormal course had to be adopted. Distillate had to be produced; it was not wanted for war purposes, and the limited storage capacity was required for crude oil and liquid fuel. We have all heard, I suppose, how in pre-motor car days benzine, i.e., petrol, was regarded by oil producers as a dangerous and undesirable waste product at a refinery, and how in consequence it was burnt in huge quantities to get rid of it. The Sarawak Distillate, however, did not share this fate, but instead, the novel plan, which originated in the fertile brain of the Chairman of the Company, was adopted of pumping it back again into the earth from which it had come. Certain wells were selected, which were known to have almost exhausted the oil sands into which they had been drilled, and about 30,000 tons of distillate was pumped back into them, the pump pressure at times rising to over 100 pounds to the square inch. Later on, in 1919, when storage and shipping conditions had become more normal, these wells were pumped again, and I am pleased to say that it is estimated that about 14,000 tons of distillate was recovered in the form of a light crude.

The total amount recovered was probably in excess of this, as the migratory powers of oil are well known, and there were evidences of this in the lighter crude which was produced from certain wells some distance from those whose production, or rather re-production, was actually measured.

By the end of 1915 the condition of the 6 inch submarine pipe line had become so bad that it was decided to lay an 8 inch line at once. The comparative failure of the first line, and the fact that Pujut had become quite an important producing centre, both pointed to the desirability of adopting the methods of launching which had already been successfully employed in Mexico. This necessitated a stretch of level ground running inland from the sea to a distance equal to the length of the required submarine line. At Miri itself, as has already been stated, there was no such stretch of ground available, but at Lutong, some seven miles to the north, there was ample space. It was also recognised that the promontory and sand banks at the mouth of the Baram River would give considerable protection against the N.E. monsoon to tankers lying off Lutong, and soundings shewed that a greater depth of water could be obtained at a reasonable distance off the shore at Lutong than at Miri.

The first 8-inch line was successfully launched in September, 1916. The length was 11,750 feet, giving a depth of water at the sea end of 28 feet at low water spring tides. This line is still in use, and three further lines have since been laid, a description of which will be given later. The line was at once taken into use and oil pumped to it from the refinery at Miri.

It was, of course, obvious that sooner or later the refinery would have to be moved from Miri to Lutong, so as to be near the tank farm and sea loading line. An additional reason was that, as originally erected at Miri to act as a topping plant, a gravity flow through had not been arranged for. Actually, owing to war conditions, the transfer was not commenced until December, 1918, and the refinery was able to start up again at Lutong in July, 1919.

As I have already pointed out, the progress of Sarawak during the period of the War, and for at least a year afterwards, was much hindered by a serious shortage of staff and materials of all kinds.

The years 1919, 1920, 1921 were devoted mainly to what I may term the consolidation of the position already gained, and in building up the necessary resources in staff and materials to make possible the greatly increased production reached in 1922. Thus while 1919 shewed an increase over the previous year of 13,000 tons, 1920 an increase of 60,000 tons, and 1921 an increase of 58,000 tons, the year 1922 was able to shew the remarkable increase of 204,000 tons—more than twice the production for 1921. The year 1923 has again shown a very marked increase over 1922 of some 150,000 tons.

The slide on the screen shews the present Miri field. The first wells, it will be seen, were drilled rather close together and were mostly shallow. Well No. 1 I am glad to say is still producing about two tons of oil a day, while well No. 8 at Pujut, which was the first well to produce 100 tons a day, is also still producing some 18 tons a day.

A better knowledge of the geological structure, the result largely of a careful record of all well logs having been kept from the very beginning, has enabled deeper drilling to be carried out successfully in areas where the shallow sands of the original field were not found to be oil-bearing. The structure, as far as is known at present, comprises three anticlines with a N.E.-S.W. strike more or less in echelon.

Recent deep drilling to the south of the old field has also given favourable results, so that a further extension of oil-bearing structure in that direction is anticipated.

Extended geological examinations of other parts of the State have revealed many surface indications of oil, but drilling results have not so far been successful in obtaining oil in commercial quantities. Further test wells are now in course of drilling, and it is hoped that a further field or fields will be proved.

Drilling and production methods call for no particular comment. They are, generally speaking, up-to-date, and every possible use is made of the gas produced on the field, both under drilling boilers and for operating gas engines at the various pumping stations.

All wells are now drilled with cable tools and Californian pattern rigs. The depth of wells varies from a little under 1,000 to over 2,000 feet, and tests are now being made for deeper sands in the same area.

At Pujut a shallow field has been developed with wells from 300 to 400 feet deep, which produce a natural fuel oil with no constituents boiling below 200°C. This crude is pumped direct to fuel oil storage tanks, so that if the Lutong refinery was completely destroyed to-morrow a certain amount of fuel oil would still be available for naval or other purposes.

To the south of the old Miri Field exploration wells drilled recently have given good results at over 2,000 feet, producing a crude oil with a higher percentage of light fractions than are obtained from other parts of the field.

A few wells have continued flowing for long periods, but most of them are pumped. Central pumping powers operated by gas engines are extensively used for pumping groups of wells, showing, of course, a very great economy over the pumping of individual wells by steam engines.

Wells in the Miri Field have, generally speaking, a long life, and a typical production curve shews that after a rapid fall during the first year the decline after that is at comparatively a very slow rate.

The refinery at Lutong at present comprises two units working on the Trumble system of distilling oil by means of tubular stills, with a combined throughput per 24 hours of about 1,500 tons of crude oil, while a third Trumble unit is in course of erection. There is now a sufficient supply of gas from the field to enable the whole refinery to be run on gas instead of on fuel oil at night-time, when the requirements of the field are low.

The properties of Sarawak crude oil were described in a recent paper read by Mr. James Kewley before the Institution of Petroleum Technologists, and I am indebted to him for the following chemical details, which may be of interest.

The crude oil is a mobile liquid of the naphthenic type, reddish brown in colour and of an agreeable odour. Its chemical nature has not yet been fully investigated, but sufficient work has been done on this oil to shew that it is of a very interesting type, and that it presents many possibilities for scientific research and technical development. This is particularly the case with regard to lubricating oils.

The products of the Miri crude at present being handled at the Lutong refinery are as follows:—

(1) A benzine of final boiling point 200°C. being about 14 per cent. of the crude. This benzine when tested in a variable compression engine has been found to withstand a compression ratio of 5.3 to 1, without appreciable detonation, *i.e.*, without what motorists call "pinking," and is therefore a valuable product.

(2) A kerosene of rather high specific gravity, which after refining can be used as a lamp oil, though not of the highest class, its best use being for internal combustion engines of the hot bulb or semi-diesel type.

(3) A fuel oil of Admiralty quality and with a low setting point having the following properties:—

Specific gravity at 15°C. ..	about 0.930
Flashpoint P.M.	175°F.
Viscosity Redwood 1 at 70°F.	75 seconds
Viscosity Redwood 1 at 100°F	49 seconds
Pour test A.S.T.M.	below 20°C.
Sulphur	0.4%
Ash	0.01%
Conradson Coking Test ..	0.7%

The residual fuel oil is thus in every respect a good fuel, not only for burning under boilers, but also for use in Diesel engines.

Having now given a short account of how Sarawak oil is produced and handled, and of the products from the Lutong refinery which are available for shipment, I would like to call your attention to the methods by which they are shipped.

The sea-loading lines at Lutong are the longest in the world, and are therefore perhaps of sufficient interest to merit a short description both of them, and of the methods by which they are constructed and laid down.

The particulars of the four lines which are now in use are as follows:—

	No. 1.	No. 2.
Launched	Sept. 1916	April, 1919
Length	11,750 ft.	13,000 ft.
Depth (L.W.O.S.T.)	28 ft.	32 ft.

	No. 3.	No. 4.
Launched	Aug., 1921	Sept., 1923
Length	14,500 ft.	14,510 ft.
Depth (L.W.O.S.T.)	36 ft.	36 ft.

The third sea-loading line, launched in August, 1921, may be taken as an illustration of the methods employed, with slight variations, in the construction and launching of all these lines.

In view of the larger size and consequently deeper draught of modern tank ships it was thought desirable to secure a depth of water at the loading terminal of not less than 35 ft. at low water. Soundings showed that to obtain this depth a length of about 14,500 feet (2¾ miles) would be required.

A clearing was first made through the jungle in a straight line for 2¾ miles from the shore to a width of from 8 to 10 yards. The actual width of the track necessary for the pipe itself, of course, is only a few feet, but the risk of a heavy tree falling on the line, possibly when just ready to be launched, has to be guarded against at all costs, and all big trees which would be a source of possible danger were also felled.

The ground at the back of Lutong is all flat, though swampy, and a considerable amount of bridging was necessary to carry the track across streams and ditches. As soon as the track was completed and levelled a light railway was laid down with a two foot gauge, referred to as the "runway." The steel pipe of 8″ diameter was then distributed along the runway, making use, of course, of the rail track for carrying it. The next step was to screw the lengths of pipe together and mount the joined lengths on a series of small trucks distributed along the runway track at intervals of about 18 yards. To give additional strength to the sea end of the line, which would have to bear the towing strain during launching, the first 12 joints were reinforced with "river clamps," *i.e.*, long sleeves made in two halves longitudinally and bolted on to the pipe over the threaded couplings. After a careful inspection and hydraulic test the pipe was given a heavy coat of hot bitumastic anti-corrosive composition, and then wrapped round with a kind of roofing felt secured in position with binding wire. On top of the felt came another coating of bitumastic and then lengths of "nebong," a sort of palm, split into lengths of 20′ or so were fastened lengthwise to the pipe and securely bound in position with wire. The object of all this wrapping is, of course, to protect the steel pipe from the corrosive action of sea water, while the nebong battens protect the pipe covering from the abrasive action of the sea bottom over which it has to be dragged.

The total weight of the line ready for launching was about 230 tons.

Further preparations for launching entailed bolting an eye to the end of the pipe to receive the shore end of the towing hawser, and the construction on the shore of massive timber guide-posts fitted with rollers to keep the line as straight as possible. To keep the end of the pipe as much as possible from embedding itself in the sea bottom, a number of empty airtight drums were lashed to it. Some means, of course, had to be adopted to ensure the pipe as it moved into the sea coming away from the trucks on which it rested. Actually a method was used by which the trucks left the pipe; on the shelving shore the runway was made to dip steeply and the track diverted to the left. In this way each truck as it reached the dip came free from the pipe and was run down a siding out of the way of the other trucks.

A signal mast and control platform were erected over the sea end of the line, giving a clear view of the towing ships and of the whole length of the line. A code of signals was arranged whereby the movements of the towing ships could be controlled from the shore, and the towing started and stopped or accelerated and slowed down as occasion required.

When all preparations had been made the launch was arranged for H.W.S.T. on a fine calm day.

A staff of 220 men in charge of 10 Europeans were distributed along the runway to prevent derailments. Telephone stations in direct communication with the Signal Station, each with a European in charge were established at the 5,000′ and 10,000′ marks, so that in the event of a derailment or accident towing could be stopped immediately.

The very great importance of making the most elaborate arrangements for control during the actual period of launching will be appreciated when it is remembered that, while the construction and preparation of the runway and pipe line take many months, the actual towing out of the line may take less than an hour.

A towing hawser some 6,000 feet long was secured to the eye at the end of the pipe line, and laid out by launches and barges until a depth of water was reached at which it could be hauled on board a tug, which with a tanker, had come as close in shore as possible.

On a signal from the shore being given the tug and tanker commenced steaming ahead on a course marked with buoys.

Once the line was started it moved evenly forward at an average rate of 3.17 knots, no derailments occurred, and the stop signal was only hoisted when some 14,500 feet of line had been successfully launched.

To complete the submarine line for service 120 feet of flexible hose 8" diameter in 20 feet lengths is coupled to the sea end of the line by a diver and the other end attached to a buoy. Tankers arriving to take a cargo are moored as shewn on the slide. The actual position of some of the buoys depends on the prevailing wind at the time of year. The flexible hose is hoisted on board over the stern together with a submarine telephone line, which is in direct communication with the pump station on shore. Orders to commence and stop pumping are given both by telephone and by signal, thus giving additional security against misunderstandings between ship and shore.

In spite of the great length of the submarine lines and the exposed position of the sea loading station in certain winds, their operation has been very successful, and during 1923 115 ships were loaded or bunkered without any mishaps or serious delays.

The approximate rate of loading for different products through these lines is: Liquid fuel, 190 tons per hour; benzine and kerosene, 140 to 150 tons per hour.

The total quantity of oil loaded through the submarine lines in 1923 was about 530,000 tons.

Sarawak Oilfields, Ltd., which now operates the petroleum industry of Sarawak, is a company incorporated in Sarawak, with its registered office there, and with two representatives of the Sarawak Government on its Board of Directors.

From the figures which I have given of production it will be appreciated that a large staff both of Europeans and of Asiatics is required. At the end of 1923 there were 133 European employees, with 42 ladies and 39 children. Also 190 senior Asiatic staff and 3,252 coolies. Miri itself has long ceased to be a primitive native village, and now possesses motor roads, railways, electric light, an automatic telephone exchange, far in advance of anything provided by the post office in London, clubs for European and Asiatic staff, a soda water and ice-plant, a farm producing milk, eggs, beef, mutton, etc., a cinema, a school for European children and another for Asiatic children, a church, a golf course, and cricket, football and baseball grounds.

The company also operates a large sawmill on the Bakong river, a tributary of the Baram river, which produces large quantities of timber both for building purposes and for the construction of drilling rigs.

From the information which I have given as to the progress of Sarawak, it will, I think, be seen that it has now an established petroleum industry which has made great strides in the last few years, and which it is hoped will continue to increase in importance as a producer of oil within the British Empire.

DISCUSSION.

THE CHAIRMAN (Lord Bearsted), said that he thought all those present would agree with him, after having heard the paper, that the subject was a very inspiring one, and showed that the age of romance was not dead yet. He wondered how many of them thought, when they travelled either in the motor car or the omnibus, of this fuel which nature had provided, and which had been in the ground for perhaps thousands of years in remote parts of the world, but which had now been brought to the surface and conveyed these thousands of miles for the use of civilisation. Perhaps the audience would agree with him that the men who went out on these ventures and made far more than two blades of grass grow where one grew before, were benefactors to the world, and, if he might say so, deserved the success they attained in the shape of any monetary reward which could be got from petroleum exploration.

There were two subjects embodied in the paper, one of them Empire oil, and the other the progress of Sarawak. He proposed in speaking to reverse this order and to deal with Sarawak first, and with the question of Empire oil second. Many instructive incidents relating to the development of Sarawak had been mentioned by the author. He had spoken of the enormous advantage of experience gained in other fields for those who would attack new ones. Then they had heard of the abnormal course that had to be pursued when the output of light products accumulated, owing to the impossibility of shipping them during the war. He thought it might be of interest if he gave the Society the financial results that ensued. Thirty thousand tons of petrol were, roughly speaking, worth about £450,000, and it required some courage to adopt a method which had never been tried before;

but the alternatives were so serious that he was glad the thought occurred to himself, as Chairman of the Company at that time, to suggest to those on the spot that as the earth was the cheapest and safest form of store, the experiment should be tried of putting these superfluous products back into the earth. They had heard from the paper that it was a success, and he ventured to say that that was of great moment for those who had to deal with eruptive wells, occasionally giving an enormous supply which swamped the country, and instead of being a blessing were a bane. As a result of that experiment at Sarawak, they now knew that they could put the product of those superfluous wells back into the exhausted ones, and yet be able probably to recover a good deal of the product afterwards when they required it.

Another point arising from the paper was the question of refining on the spot. The author had told them that there was a sufficient supply of gas from the fields to enable the whole of the refinery to be run on gas instead of fuel oil when the requirements of the field were low. Could anything be imagined more unwise than to remove oil which could be refined at the point of production and take it away for refining purposes, as was done in some cases to a distance of thousands of miles? The only possible reason for that unnatural proceeding must be political, and those Governments which imposed very high rates upon refined products and allowed crude products to be brought in not free of duty, but at a low duty, failed to recognise the economic loss which was caused by those proceedings, or he thought they would alter them. They had a great deal to be thankful for that certain neighbouring countries had pursued that course, because the progress of mechanical traction depended upon a large and cheap supply of fuel, and that was not possible, and never would be where uneconomic methods were used to produce it. The oil obtained at Pujut was quite extraordinary in its character. It was a natural oil, and in common with an oil produced in the centre of the Dutch East Indies, it was a solvent, when met with too resinously. There were few petroleum sources in which light fractions were able to be taken off and a good liquid fuel to be left. In the great majority of such cases, the taking off of the light products left a fuel of such great viscosity that it was impossible to use it, but this company had the advantage that a mixture of that fuel with heavy fuel made the latter marketable. Again, the quality of the oil was such as to enable it to be used in Diesel engines, and that was very important, because the Diesel-engine ship was the ship of the future. The tonnage now building throughout the world showed that nearly 40 per cent. of the vessels under construction were for the internal combustion engine, and the production of oil was of enormous importance, because, used for internal combustion, it represented an economy of nearly 3 to 1 compared with using it under the boilers. The latter was a barbarous method of using the material, and he wondered what their successors a generation or two hence would say with regard to the foolishness of those in the past who had burned oil. It was satisfactory to know that at Sarawak there was a depth of water at the loading terminal of 35 feet at low water, which meant that the largest ships afloat could bunker there.

The Sarawak Oilfields, Limited, which now operated this field, was a company under the laws—the liberal laws—of Sarawak, where, he believed, the income tax was unknown, and where directors, contrary to the methods in our own country, which ought to be altered, were at liberty to make proper appropriations for depreciation without let or hindrance. It was a pitiful thing that companies here were not allowed to make sufficient allowance for depreciation, but were charged income tax, not only on the supposed profits, but also on sums which should be put to depreciation, and which, in an oilfield, represented a real consumption of capital. It was quite true that they received the proceeds of the oil, but it had to be remembered that that oil was never replaced; it had disappeared, and it should be written off as part of the capital if the company was to operate under the very best auspices.

The author had told them that Miri was no longer a native village, and it would have been seen from the photographs that every amenity that the Directors of the company could afford was willingly given to the town. He knew the work of that Company; he could speak of it in a spirit of detachment, because he left it three years ago, and was now not in business at all, and he could say that the Directors had made it their business to see from the start that the employees who were carrying the flag abroad should have the best conditions in which to live and work, and should be provided for in their old age by the establishment of a large provident fund in which all of them shared. After a certain number of years all the employees in that company would find themselves amply provided for.

The geographical position of this field had been illustrated by means of maps, but it was very difficult to gather from them how important it was. That this field was an immense asset to the British Empire none would dispute. The distance from Singapore was only 630 miles, less than three days' steam, and the distance of any other source from Singapore (except the Dutch East Indies, which was very close) was 3,938 miles. In the light of these distances, the importance of this field to the British Empire would be better realised. From Hong Kong the distance was 1,080 miles, and the representative of the Japanese Navy, who was present in the audience that afternoon, would be interested to hear that the distance from Yokohama was only 2,600 miles, while the distance from Yokohama to San Francisco, the next nearest source, was 4,550 miles. Thus they would see that it was a matter of very great moment that the geographical advantages of this position should be realised. Personally he felt persuaded that the distribution of oil would, in the future, be guided by the proximity of the bases of production, and they would not see the terribly wasteful methods of transport which now prevailed, wherein oil was brought from very great distances, when it might be obtained quite near at hand. That was particularly appropriate to Australia. Sarawak was only 4,350 miles from Newcastle, N.S.W., and 4,430 miles from Sydney. The Australian Government—he assumed before they were aware of the large production likely to be forthcoming from Sarawak—had arranged for their supplies from another source, from which Newcastle was 7,740 miles distant, and Sydney 7,522 miles. Therefore, Sarawak was splendidly placed for supplying the needs of neighbouring countries. All this, of course, had its political aspects too. The bearing of the development of this field on the Singapore base was a very important one indeed. The Admiralty, of course, knew its business thoroughly, but probably it was not realised that a field had been found in British territory, and, of course, under British control, only three days' steam away from Singapore. The question of the protection of Sarawak was an extremely important one from that point of view, because it was inconceivable that we could ever allow that wonderful field—as he believed it would be found to be—to fall into enemy hands. He did not like to envisage an enemy in those waters. He had seen the evils in the oil scandals which had arisen lately in the United States, where it was argued that Hawaii was a necessary port for the American Navy, in view of the fear of an alliance between Great Britain and Japan to attack the United States. That was a midsummer madness. He declined to believe—although he supposed they must provide for every contingency—that they were going to see any alliance of that kind, any more than an alliance of the United States and Japan for the purpose of invading the British Colonies. He did not believe in it one bit.

He now came to the question of the development of oil in the British Empire. As one who had made it almost the passion of his life to see that come about, he wished to utter the strongest protest he could against the development being attempted by Governments. He saw with dismay the association of the Australian Government with the British Government for the purpose of developing oil in Papua and New Guinea. Hundreds of thousands of pounds had been spent, and no results obtained. He was thoroughly persuaded that the future of the British Empire depended on the efforts and ability of individuals, and he hoped everyone in that room would protest if they got the chance—and the chance came at the polling-booth—in the hope of dissuading the Government from entering into any such trade, especially a trade which had the immense risks of oil, and which would bring them into competition with all other companies and nationalities, involving sometimes, as had been seen, the most grave political troubles. An instance of the kind arose in Egypt, and in that connexion he was glad to see Sir Henry McMahon, Government director of the Anglo-Egyptian oilfields, there that afternoon. The Egyptian oilfields were developed by British enterprise. They had been attempted by the Americans, and the only effect was that the Americans left the field water-logged, and it had not been possible to get it right yet, and he was afraid it would never be. Incidentally he would like to say that Sarawak was very fortunate in that the Government and the company worked hand-in-hand without the slightest fear of friction, because the remuneration of the Government was by means of royalties. He could not imagine anything more unfortunate than the participation of Governments deriving their royalties from profits. That was a fruitful source of trouble. But to return to Egypt. Thanks to the prescience of Lord Kitchener, the Government took an interest in this case. Lord Kitchener laid it down at a time when there was no production there, and when it was doubtful whether there would be profits or not, that the Egyptians had to be considered and that regard must be had to the future. That was quite right, but he (Lord Bearsted) did not think anybody ever contemplated that when success was attained the Egyptian Government should go into business themselves in opposition to the Company in which they had got an interest. The result had been very extraordinary indeed. The Government had attained no success whatever, but they had spent, he should think, at least half a million in trying for it, and it only showed again that these ventures were much better left to private enterprise, because individual Directors who were responsible for the public money were much more likely to exercise care than the Government. He sincerely hoped and firmly believed that in Sarawak, as elsewhere, it would be proved again that trade invariably followed the production of oil, and that Sarawak would not only be a great centre for oil, but that the trade done there in the future would eclipse anything that the noble and enterprising founder of the Colony ever foresaw.

Lt.-Col. Sir Percy Cunynghame, Bt., O.B.E., said that he was afraid he could not tell the meeting very much about the progress of Sarawak as it was to-day, because he left it in 1909, and at that time he thought the Company had only just obtained their concession. The country had not then the great advantage of the genius and foresight of Lord Bearsted and those who were assisting him in its development, but they had nevertheless, a certain amount of European capital. They had the gold mines, which for a long time yielded a high profit. These had now been closed down. It was a country, however, which was potentially very rich, and, of course, as they knew, after hearing the lecture and also the most illuminating address which Lord Bearsted had given, immense possibilities awaited its development. When he was in Sarawak he was in the service of the late Rajah, Sir Charles Brooke, a man for whose memory he had a great esteem. He was a man who regarded his country and his people as a sacred trust, and when he came to consider any question connected with Sarawak, the Rajah always asked himself first the question whether this would be to the advantage of the country itself and of its people. Of course his actions were criticised, and supposed to be too conservative. People said that if European capital had been allowed to operate earlier the development of the country might have been quicker. But the answer to that was that when the present Rajah came into this inheritance, on the death of his father, he found a country which was unencumbered with debt, whose taxation was light, and whose population was loyal and absolutely devoted to the Brooke regime. They were fortunate to-day in the inhabitants they had in Sarawak. The generally-accepted idea of the Malay was that he was rather a treacherous and bloodthirsty individual. Personally the speaker had never found him so, but, on the contrary, a very lovable person, who was capable of showing loyalty and devotion to the European whom he knew and trusted. The Malays had thoroughly proved their loyalty to the British Rajah. In the days of the Chinese insurrection, when the Rajah was himself a fugitive, and had to throw himself on the protection of this subject race, the Malays rallied round him and protected him until such time as a force could be got together which could drive the Chinese out of the country. This was the more remarkable because the Chinese insurrection was not directed against the Malays at all, but against the whites. The action of the Malays was a proof of what could be done when natives trusted and liked Europeans. He thanked the lecturer and Lord Bearsted for what they had said. To him it had been most interesting, because it had enabled him to follow the progress of the country in a way that he had never been able to do in reading about it in pamphlets and books.

Sir Henry McMahon, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I., said that they would all agree that the Society had been given a most interesting description of the birth and growth of Sarawak. Nowadays they heard so much about oil that anything connected with its production must be of interest. But the Sarawak field that they had heard of that evening was a very much more important one than might be assumed from its actual size. As the Chairman had said, it owed its importance to its geographical position. Oil was now becoming the predominant motive power of the world, and this was especially the case at sea. The geographical position of oil-fields in relation to trade routes was becoming a more and more important question. Lord Bearsted had referred to his own connexion with the Anglo-Egyptian oil-fields. Egypt during the war was called—the Clapham Junction of the world. It was very fortunate that just alongside that Clapham Junction of sea-borne traffic there was a very useful and productive oil-field, which was worked at great pressure to meet the necessities of the War, and produced about 5,000 tons a week. That was at a moment when ships were not obtainable, and it was a very difficult matter to convey oil to Egypt. That supply of 5,000 tons a week came in very useful indeed, not only to industry, but to the British Government. There was now another Clapham Junction of equal importance in the world, some people would say of even more importance. This Clapham Junction was the Malay States and Singapore, and they had been hearing that evening of a conveniently-situated oil-field, not very far from that strategic centre. It was a very fortunate thing to find oil-fields under British control close to these great junctions. Yet, after all, it was not entirely a matter of fortune. It was the result of shrewd and far-reaching vision and of bold enterprise, and he would let the Society into a secret. They were indebted for that vision and that enterprise to Lord Bearsted, the Chairman of that meeting.

Mr. Byron Brenan, C.M.G. (late Consul-General for Shanghai), proposed a vote of thanks to the reader of the paper, and to Lord Bearsted for taking the Chair. He was sure the Society had heard the lecture, not only with interest, but with pleasure, because the lecturer had invested an uninteresting subject like the production of oil with a certain atmosphere of romance. They all liked to know whence came the products which many of them used, and all of them used oil in different ways. Some used it for motor cars, others for lamps, others again in humble ways to stimulate the growth of hair or to remove grease spots from waistcoats! But they were all interested in the subject. He thought that the author of the paper might be a thorn in the side of the Chancellor of the Exchequer if he drew any of them away to that happy land where they escaped income tax. They were much indebted to Lord Bearsted for sparing his valuable time to come there that day. In anything connected with petroleum his name was a household word. He had given them a hint what to do with their surplus goods, namely, to put them back into the earth, and he imagined that he had got the idea from watching the squirrels in Regent's Park!

The resolution was carried unanimously.

Mr. Cochrane said that he was instructed by Lord Bearsted to reply on his Lordship's behalf as well as his own. As far as he himself was concerned it had been a great pleasure to endeavour, however inadequately, to give some idea of the present position of the Sarawak oilfields, and any who had found his paper dull had at any rate had the advantage of hearing a speech from Lord Bearsted in which he had dealt with a number of other places besides Sarawak, which were perhaps of more general interest to the audience.

He wished to thank Mr. Brenan and the audience on behalf of Lord Bearsted and of himself for the very kind way in which the vote of thanks had been proposed and accorded.

Mr. H. Wyndham Jones writes:—

In the early part of his paper Mr. Cochrane mentions that Sarawak Government officials reported the coast near Miri to be unapproachable from September to March, viz.—the North-east Monsoon season.

Later, he states that during 1923 no less than 530,000 tons of petroleum were shipped from Miri in 115 tank vessels, which means an average of 1,450 tons a day or a tank vessel every three days or so.

This shipment of petroleum is not effected only during the favourable monsoon season, but must of necessity be carried out throughout the year. In addition, it is necessary to ship to Miri in the course of the year, several thousands of tons of drilling material, casings, pipe lines, machinery and general supplies. These shipments also must be made continuously throughout the year, but are seldom made on tank vessels, for various reasons.

Those of the audience who are acquainted with the Indian Ocean and China Seas will know that the fury of the monsoons has not abated. The Port of Miri is still an open roadstead with but a slightly curved beach-line, and entirely exposed to weather coming from the west, the north and the greater portion of the north-east quadrant. Mr. Cochrane has mentioned that the bar at the mouth of the small Miri River carries only one foot of water at low water spring tides. It happens also that "tides" at Miri are peculiar in so far that in general there is but one high tide during each 24 hours, although during "slack" or neap tide periods a slight supplementary tide is sometimes noticed; under these conditions all incoming cargoes have to be handled.

The foregoing observations are intended to emphasise the difficult conditions which have to be faced at Miri and the high grade of efficiency that is organised and maintained to cope with the shipping side of the business.

OBITUARY.

William Henry Maw, LL.D., M.Inst.C.E.—Dr. William Henry Maw died after a very brief illness at his residence in Addison Road, Kensington, on March 19th, at the age of 85. He will be greatly missed at the Royal Society of Arts, where he was a regular attendant at meetings of the Council and of the Finance Committee. He joined the Society in 1890. In 1911 he was elected a member of the Council, on which he served until 1914, and again from 1917 onwards. In 1919 he was appointed one of the Society's Treasurers, an office which he held up to the time of his death.

Dr. Maw was born at Scarborough in 1838. After spending ten years in the works of the Great Eastern Railway at Stratford, in 1866 he joined the staff of *Engineering*, of which he continued to be a joint editor all the remainder of his life. In addition to this work he practised as a consulting engineer, and he took a keen interest in the work of various technical institutions. He was President of the Institution of Mechanical Engineers in 1901-2, and of the Institution of Civil Engineers in 1922-23. He assisted in the formation of the Engineering Standards Committee in 1901, and he was a member of the Royal Commission for the St. Louis Exhibition in 1904. During the war he served on the Advisory Panel of the Munitions Inventions Department of the Ministry of Munitions.

Dr. Maw was a very keen astronomer and microscopist. He was at one time president of the Royal Astronomical Society and of the British Astronomical Association. He was the author of a paper on "Double Star Observations," and of a book on "Recent Practice in Marine Engineering," and was joint author of "The Waterworks of London" and "Road and Railway Bridges." He received the honorary degree of LL.D. from the University of Glasgow in 1909, and last year the Iron and Steel Institute awarded him the Bessemer medal.

NEW INDUSTRIES FOR MALAYA.

Extensive experiments in the cultivation of crops other than rubber and coconut are being conducted by the Department of Agriculture of the Federated Malay States and the Straits Settlements, writes the United States Consul General in Singapore. The object is to determine what crops, especially those of quick maturity, are most suited to native production. The step is indicative of the increasing interest throughout Malaya in the development of more diversified production as a result of the recent rubber and tin depressions and the consequent restriction in export acreage.

An area of 450 acres on a new plantation at Serdang has been cleared for the purpose and divided into regular blocks for the planting of various crops. Careful records are to be kept and experiments on short-duration crops will be repeated until definite data are obtained. At the present time there are over 100 different species of plants on the plantation and a large number of different varieties of the same species in a number of cases. The principal crops included in the plan with the approximate area allotted to each, are the following: African oil palm, 50 acres; limes, 50 acres; sugar, including 23 varieties of Malayan and Javanese canes, 25 acres; kapok, 50 acres; sisal hemp, 25 acres; Mauritius hemp, 25 acres; manila hemp, 4½ acres; roselle fibre, 3 acres; coffee, including robusta and five different Javanese varieties, 10 acres; croton-oil, 9 acres; candle nut, 8 acres; cocaine, 5 acres; papaya, 2 acres; and bananas, 437 numbered lots comprising approximately 125 varieties collected from various sections of the Malay Peninsula. The nurseries are well stocked with material for planting to carry out the present programme.

THE EGG TRADE OF EGYPT.

According to reliable unofficial estimates, writes the United States Consul at Alexandria, the production of eggs in Egypt is approximately 150,000 cases per annum, each case containing 1440 eggs. About 70 per cent. of this production is exported.

For commercial purposes Egyptian eggs are divided into three classes. Fayoum eggs, produced in the fertile province of Fayoum, south-west of Cairo, constitute the first class. Because of their relatively large size they sell at higher prices than any other eggs. Beheri, or Delta, eggs, produced in the triangular area between the two branches of the Nile below Cairo, constitute the second class. The third and lowest-priced class consists of Saidi, or Upper Egypt, eggs.

The principal purchaser of Egyptian eggs is the United Kingdom, which takes more than 90 per cent. of Egypt's total exports of this commodity. The following table, compiled from official Egyptian customs statistics, shows the quantity, value, and destination of eggs exported from Egypt in 1921 and 1922 :—

Destination.	1921		1922	
	Number in thousands.	Value.	Number in thousands.	Value.
		LE		LE
United Kingdom	87,960	326,316	156,907	503,979
British Mediterranean possessions	229	890	72	194
France	1,699	5,803	2,881	9,378
Palestine	322	1,133	80	272
Spain	1,194	4,168	39	136
Syria	50	218	......	......
Turkey	72	288	82	287
Other countries	275	963	191	531
Total	91,801	339,770	160,252	514,777

LE=£1 0s. 6¼d.

Active shipments of eggs from Egypt begin in November and continue until July. Maximum shipments occur from January to April. Eggs are usually shipped by Alexandria produce exporters either on consignment or to agents on a commission basis.

COTTON GROWING IN AUSTRALIA.

An article dealing with the present position of cotton-growing in Australia and the possibility of the Dominion becoming an important source of supply, is published in the current issue of the "Bulletin of the Imperial Institute." The author, Mr. W. H. Johnson, who was at one time Director of Agriculture in the Southern Provinces, Nigeria, recently paid a visit to Australia to report on the suitability of different parts of the country for cotton cultivation.

In 1788, Governor Philip brought cotton seed from South America to plant in Sydney, and since then many attempts have been made to grow cotton in Australia. The first bale of cotton exported from the Dominion was produced in Queensland in 1852. With the help of premiums paid by the Government and the high prices ruling as a result of the American Civil War, production increased and, in 1871, shipments from Queensland amounted to 2,602,100 lbs. Subsequently, the industry declined, and, with the exception of a slight revival in 1890, remained practically dormant until the last few years. Considerable interest has now been again aroused. The Queensland Government are encouraging the growth of the industry by providing cotton seed free of charge for planting purposes, and by paying farmers a guaranteed price for seed-cotton ; assistance is also being rendered by the British Cotton Growing Association. In 1922, an area of 7,000 acres was planted with cotton in Queensland and the yield of seed-cotton by the end of August had amounted to over 3¾ million lbs. Mr. Johnson discusses the problems confronting the planter in the various regions where cotton growing has been proposed, and concludes that the soil and climatic conditions in large portions of Queensland, Northern New South Wales, North-West Australia, and in the Irrigation Settlements of Victoria, New South Wales, and South Australia, are well adapted for cotton cultivation, but carefully conducted trials will be necessary to decide whether the crop can be grown profitably on a large commercial scale.

WATER POWER RESOURCES OF THE DUTCH EAST INDIES.

In his recent report on the Economic Situation of the Netherlands East Indies, the British Commercial Agent at Batavia states that the total water power available in the Netherlands East Indies amounts to 5,500,000 h.p. divided amongst the various islands, of which Java possesses 500,000, Sumatra 2,000,000, Borneo 2,000,000, and Celebes 1,000,000 h.p. Of this total only 60,000 to 70,000 h.p. has up to the present been exploited.

In the above schedule New Giunea has not been included; the power exploitable in this island alone amounts to 5,000,000 h.p.

The harnessing of water power and the erection of electric generating plants are stimulated in Java by the abundance of cheap labour available, and by the plentiful supply of building materials which may be obtained locally. Nearly all concessions granted are for medium and high falls, that is to say from 50 to 200 metres. The two types of water turbines which are at present exclusively used are the Pelton wheel and the Francis turbine. With very few exceptions, all installations now being erected are of Swiss or German origin.

No attempt has yet been made to harness low falls of water, owing to the large initial capital outlay entailed thereby, although the water supply available at the Asahan, Ombilin and other rivers in Sumatra, which would necessarily be low falls, have been completely surveyed, and will no doubt be developed as soon as money is more plentiful, and the large capital required can be found.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

April 2.—Sir Lynden Macassey, K.B.E., "London Traffic." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

April 4 (Monday at 4.30 p.m.).—George Macaulay Booth, Director of the Bank of England and of the Booth Steamship Co., Ltd., "The Amazon Valley and Its Development." H. E. the Brazilian Ambassador will preside.

April 9.—Frank Hope-Jones, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." Professor C. Vernon Boys, F.R.S., will preside.

April 30.—Brigadier-General Sir Henry Maybury, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "The London Dock District and its Roads."

May 5 (Monday).—T. Thorne Baker, "Photography in Industry, Science and Medicine."

May 7.—J. Robinson, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation." Admiral of the Fleet Sir Henry Jackson, G.C.B., K.C.V.O., F.R.S., will preside.

May 14.—

May 21.—Professor C. Vernon Boys, F.R.S., "Calorimetry." (Trueman Wood Lecture.)

May 28.—Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Indian Section.

Friday afternoons, at 4.30 o'clock:—

May 2.—Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced:—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

Dominions and Colonies Section.

Tuesday, May 27, at 4.30 o'clock.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Wednesday, June 4, at 4.30 o'clock.—The Rt. Hon. Sir Frederick Lugard, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates."

Monday, June 16, at 4.30 o'clock.—C. V. Corless, M.Sc., LL.D., "The Mineral Resources of Canada: The Pre-Cambrian Area."

Cobb Lectures.

Monday evenings, at 8 o'clock:—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

Syllabus.

Lecture II: March 31.—Hardening of gelatin. Ordinary fixing and acid fixing baths.

Medium free silver halide. Gelatine as a retarder of development. Black and grey silver images. Coloured silver images and silver colour scale. Production of coloured images Gelatine as a sensitiser.

LECTURE III: APRIL 1.—Photohalides and the visible image. Sensitising action of silver ions. Latent image. Duplication of light action by chemical agents. Silver halide grain as the unit. Sensitive centres on the grains. Nucleus exposure. Nature of the sensitive centres.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, MARCH 31 Farmers' Club, at the Surveyors' Institution, Great George Street, S.W., 4 p.m. Mr. J. Wyllie, "How to adapt the Methods of Farming to the changed conditions of Agriculture."

British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. H. S. Goodhart-Rendel, "English Gothic Architecture of the 19th Century."

Electrical Engineers, Institution of, Victoria Embankment, W.C., 7 p.m. (Informal meeting). Mr. F. Gill, "Economics in Engineering."

Society of Chemical Industry and Institute of Chemistry. Joint Meeting, at Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. Films on "Coal and its Products," and "Heavy Chemicals."

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C. 5 p.m. Discussion on "The Inclusion of Disability and Fatal Accident Benefits in Life Assurance Contracts."

TUESDAY, APRIL 1 Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. G. Gordon, "Ballads." (Lecture II.)

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m. (1) Mr. D. H. Remfry, "The Interaction in Bridgework of the Deck System on the Main Girders, and the consequent modification of stresses therein." (2) Prof. C. E. Inglis, "Theory of Transverse Oscillations in Girders and its relation to live-load and impact allowances."

Alpine Club, 23, Savile Row, W., 8.30 p.m. Mr. R. A. Frazer, "A Plea for Mountaineering in Central Spitzbergen."

Photographic Society, 35, Russell Square, W.C., 7 p.m. "The Making of a Topical Film."

Zoological Society, Regent's Park, N.W., 5.30 p.m. (1) Mr. O. Thomas, and other European Mamalogists, *Nomina Conservanda* in Mammalia. (2) Dr. W. N. F. Woodland, "On a new Species of Cestode of the Genus *Caryophyllœus*, from an Egyptian Siluroid. (3) Dr. C. H. Joh. Petersen, "The Necessity for Quantitative Methods in the Investigation of Animal Life on the Sea Bottom." (4) Prof. R. T. Leiper, "An Account of the Parasitological Work at the Society's Gardens."

WEDNESDAY, APRIL 2 London County Council, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Sir Napier Shaw, "Modern Meteorology." (Lecture VI.)

Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. (Wireless Section). Messrs. M. Thompson and A. C. Bartlett, "Thermionic Valves with Dull-Emitting Filaments."

British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 3 p.m. Annual General meeting.

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m. (Students' meeting). Engineer-Captain J. A. Richards, "The Manufacture of Solid-Drawn Steel Tubes."

Public Analysts, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. (1) Mr. J. Golding, Report on The World's Dairy Congress held at Washington, D.C., U.S.A. (2) Messrs. L. H. Lampitt, E. B. Hughes, and M. Bogod, "The Routine Examination of Dairy Products with special reference to the Mojonnier Tester." (3) Dr. J. C. Drummond, Miss M. G. Palmer, and Miss D. E. Wright, "Experiments on the Absorption of Copper following the Consumption of Vegetables containing Copper Sulphate." (4) Messrs. J. H. Lane and L. Eynon, "Determination of Sugar in Urine by means of Fehling's Solution with Methylene Blue as Internal Indicator." (5) Miss P. H. Price, "Attempt to extend Mitchell's Colorimetric Method to the Catechol Tannins."

THURSDAY, APRIL 3 Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Colonel the Master of Sempill, "The British Aviation Mission to the Imperial Japanese Navy."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W.

Linnean Society, Burlington House, Piccadilly, W., 5 p.m. (1) Mr. C. Turner, "Further notes on the development of *Staurastrum Dickiei van parallelum nordst.*" (2) Dr. H. S. Holden, "On tyloses and cavity parenchyma in Ferns." (3) Dr. H. S. Holden and A. Evelyn Chesters, "On the seedling anatomy of certain species of *Luninus*." (4) Mr. W. O. Howarth, "Occurrence and distribution of *Festuca avina* in Britain."

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. (1) Mr. E. H. Ingold, "The Tautomerism of Dyads.-Part II. Acetylene and its Halogen Derivatives." (2) Messrs. H. Bassett and D. J. T. Bagnall, "The Potassium Salts of Phenolphthaloin." (3a) Messrs. H. Bassett and A. S. Corbot. "A Phase Rule Study of the Cupro-, Argento-, Auro-, and Thallo-Cyanides of Potassium." (3b) "The Hydrolysis of Potassium Ferricyanide and Potassium Colbaticyanide by Sulphuric Acid."

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Dr. J. E. Borland, "Music in the Schools."

Mechanical Engineers, Institution of, (Local Section). Royal Technical College, Glasgow, 7.30 p.m. Mr. D. Fife, Boiler Construction and Maintenance.'

Royal Institution, Albemarle Street, W., 5.15 p.m. Dr E. J. Allen, "Scientific Research on Sea Fisheries." (Lecture I.)

FRIDAY, APRIL 4 Royal Institution, Albemarle Street, W., 9 p.m. Prof. Sir E. Rutherford, "The Nucleus of the Atom."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, (Informal meeting), 7 p.m. Discussion on "Mechanical Methods of Boiler Firing."

(Yorkshire Section), Philosophical Hall, Park Row, Leeds, 7.30 p.m. Mr. F. Darley, "Design and Manufacture of Steel Castings."

Engineers, Junior Institution of, 39, Victoria Street, S.W., 7.30 p.m. Mr. A. J. Sear, "Mineral Oils, with special reference to Lubricating and Inculating Oils."

Geologists' Association, University College, Gower Street, W.C., 7.30 p.m.

Philological Society, University College, Gower Street, W.C., 5.30 p.m. Prof. W. A. Craigie, "Dictionary Evening."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Messrs. A. C. Banfield and B. Cox, "The Oil Processes." (Demonstration.)

SATURDAY, APRIL 5 .. Royal Institution, Albemarle Street, W., 3 p.m. Dr. C. Singer, "Aristotle as a Biologist."

Journal of the Royal Society of Arts.

No. 3,724. VOL. LXXII.

FRIDAY, APRIL 4, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.(2)

8 MAY 1924

NOTICES.

NEXT WEEK.

Monday, April 7th, at 8 p.m. (Cobb Lecture.) **Dr. T. Slater Price**, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." (Lecture III.)

Wednesday, April 9th, at 8 p.m. (Ordinary Meeting.) **Frank Hope-Jones**, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." **Professor C. Vernon Boys**, F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

SIXTEENTH ORDINARY MEETING.

Wednesday, March 26th, 1924; **Professor E. W. Macbride**, D.Sc., F.R.S., in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Eedy, Arthur Malcolm, Sydney, Australia.
Muir, James, London.
Rothfeld, Otto, I.C.S., London.

The following candidates were duly elected Fellows of the Society:—

Campbell, Andrew, Beckenham, Kent.
Sharp, Mrs. Katharine Dooris, London, Ohio, U.S.A.
Williams, Professor Clement Clarence, Urbana, Illinois, U.S.A.

A paper on "The Fishing Industry and its By-Products" was read by **Mr. Neal Green**.

The paper and discussion will be published in a subsequent issue of the *Journal.*

COBB LECTURE.

Monday Evening, March 31st, 1924; **Dr. T. Slater Price**, Director of Research, British Photographic Research Association, delivered the second lecture of his course on "Certain Fundamental Problems in Photography."

The lectures will be published in the *Journal* during the summer recess.

VISIT TO THE GUILDHALL.

On behalf of the Fellows of the Society and their ladies, the Council have gratefully accepted an invitation from Mr. H. G. Downer, LL.B., a member of the Common Council, to inspect the Guildhall, including the Art Gallery of the Corporation of London, on Thursday, May 8th, at 2.30 p.m.

Sir Alfred George Temple, F.S.A., will act as escort in the Art Gallery and Mr. Deputy Alderton, C.C., in the Council Chamber, Crypt and other places of interest in the Guildhall.

Fellows desirous of availing themselves of the invitation should inform the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.2, on or before May 3rd, mentioning the number of their party.

Those attending are requested to assemble at the main entrance to the Guildhall in King Street, Cheapside, at 2.30 p.m.

PROCEEDINGS OF THE SOCIETY.

EIGHTH ORDINARY MEETING.

Wednesday, January 30th, 1924.

Sir Herbert Jackson, K.B.E., F.R.S., in the Chair.

The following paper was read:—

THE HISTORY, DEVELOPMENT AND COMMERCIAL USES OF FUSED SILICA.

By **Sir Richard Arthur Surtees Paget**, Bt.

Silica is the commonest constituent of the earth's crust. It is estimated that of the first 10 miles' depth, 60% consists of silica (SiO_2)—occurring as quartz rock, sandstone and other forms of SiO_2—either free, or combined with metals or metallic compounds in the form of silicates, or the like. The "full dress" form of pure silica is rock crystal, from which all the highest grades of transparent fused silica are made. Deposits

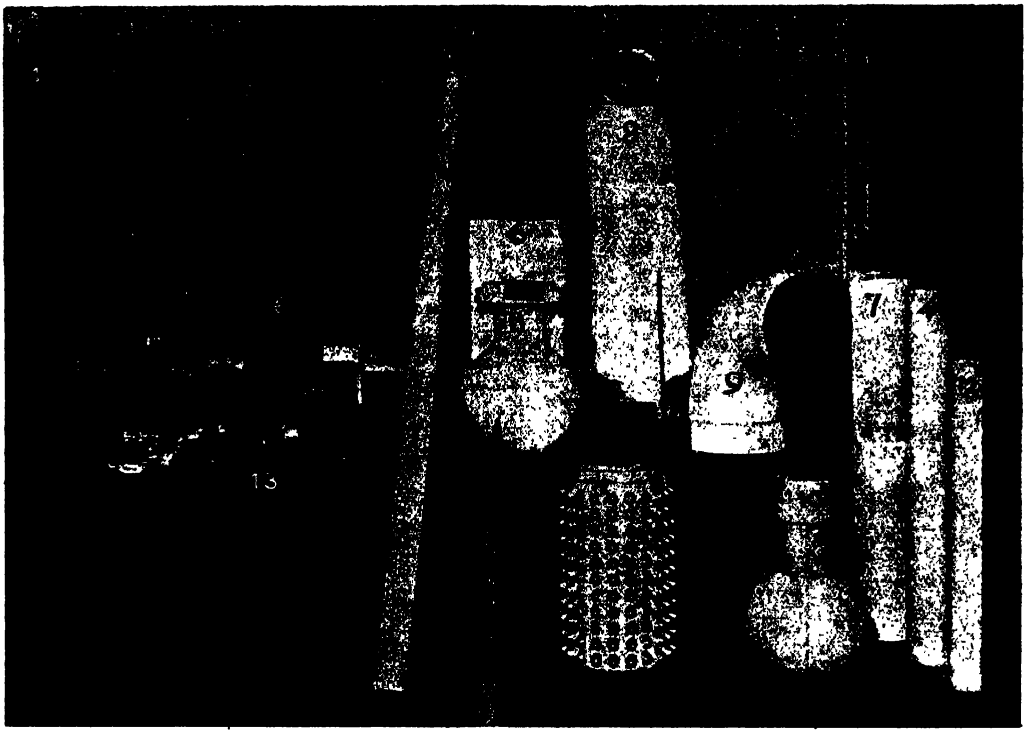

Fig. 1.—Photograph of Exhibits (transparent and heavy chemical ware, etc.)

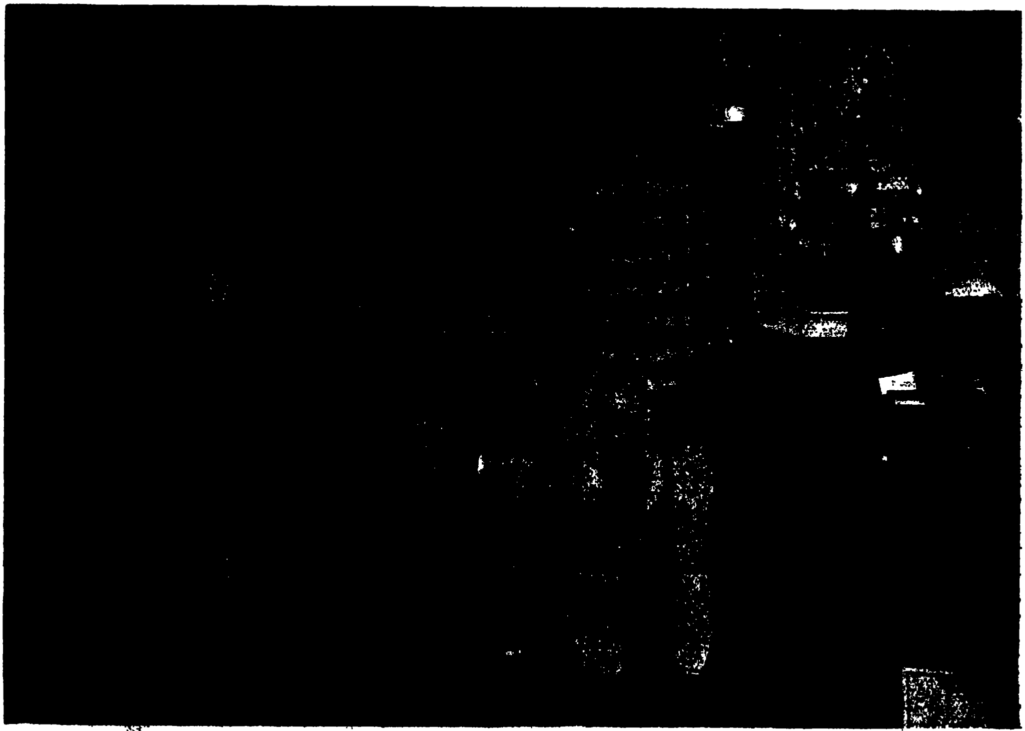

Fig. 2.—Photograph of Exhibits ("Ostrich Egg," big flask, Brussels Exhibition fire exhibit,etc.)

of large crystals are of comparatively rare occurrence. Next, in order of utility for our purpose, may be placed the deposits in the form of small crystals of rock crystal, which occur in Germany, Sweden and elsewhere and are commercially known as geyserite. True geyserite is a semi-hydrated silica of the opal type, deposited by water containing dissolved SiO_2. Lastly there is silica sand—the principal raw material of the glass-maker—which, in varying degrees of purity is found throughout the world. For the manufacture of fused silica ware only the highest grades are suitable, *i.e.*, with a silica content of about 99.8.% No such deposits are known in this country and all sand for fusion is at present imported from France.

Silica also occasionally occurs in other crystalline forms, namely, as Tridymite (in certain volcanic rocks) and more rarely as Crystobalite. These forms are of no importance as sources of silica, but are very material (as we shall see later) in connection with the behaviour of fused silica under heat treatment.

Natural fused silica—fused by the earth's internal heat—occurs in certain volcanic rocks. The earliest experiments in silica fusion on the earth's surface were made by Nature herself and consisted in passing a very high tension static discharge (in other words, a flash of lightning) through a bed of silica sand.

The result is a rough tube of fused silica usually of ¼″ to ½″ diameter, glassy on the inside, but with an unfused sandy exterior. These tubes—known as Fulgurites or Le chatelierite — have been discovered in lengths up to 37ft. at Drigg in Cumberland. The present small samples come from Maldonado in Uruguay and from Griqualand in South Africa. Fulgurites were first observed in 1711 by Pastor L. D. Hermann at Massel in Silesia and were attributed to lightning, in 1805, by Dr. Hentzen in Westphalia. The Drigg specimen is described by E. L. Irton, Trans.: Geolog. Soc., 1814, Vol 2, p. 528. Darwin refers to the Uruguayan fulgurites in his geological observations (Voyage of H.M.S. "Beagle.").

In 1839 Gaudin of Paris, communicated to the Academy of Science his experiments on quartz (*i.e.* silica) fusion. Gaudin used the oxyhydrogen blowpipe; he found (1) that fused quartz never became truly fluid; (2) that it began to volatilise near its melting point; (3) that on cooling it became a transparent glassy mass; (4) that in this condition the material was unaffected by sudden changes of temperature, and showed remarkable strength and elasticity; (5) that on prolonged heating the vitreous quartz returned to the crystalline condition, *i.e.*, it became devitrified, and lost its mechanical strength. If nature herself is the mother of fused silica, Gaudin may fairly claim to be its father.

In 1878 Gautier exhibited small fused quartz tubes made in the blowpipe.

In 1887 Vernon Boys devised his beautiful method of drawing very fine quartz threads by means of a miniature crossbow and arrow. (Fig. 3.) The flight of the arrow was made to draw out a thin rod of fused quartz heated in the blowpipe, and threads up to 30ft. in length were produced in this way.

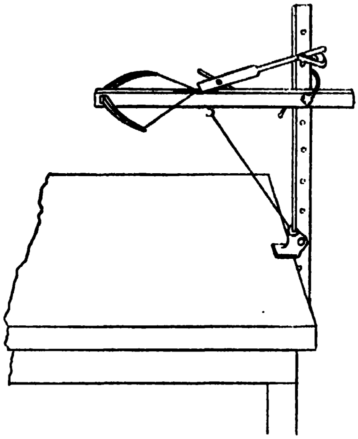

Fig. 3.—General arrangement of Boys's apparatus for making quartz fibre.

In 1888 Sir Charles Parsons communicated to the Royal Society a series of experiments, including that of fusing silica sand by means of an electrically heated carbon rod embedded in the sand—the fusion being carried out inside a closed cylinder and under a pressure of five to thirty tons per sq. inch. This is, I believe, the first instance in the history of silica fusion of the use of a carbon resistance rod, which has since become the standard system of heating.

Threlfall's "Laboratory Arts" (Macmillan 1898) describes the preparation of quartz fibres and the manufacture of insulators, etc. In 1899 Threlfall, at Oldbury, fused quartz in quantity in a 100 k.w. arc furnace, but did not succeed in working it.

In 1900 Schott and Genossen exhibited a fused quartz lens at the Paris Exhibition.

In 1901 Shenstone demonstrated at the Royal Institution his method of building up fused silica tubes by drawing pieces of rock crystal out into thin rods in the O-H blowpipe, assembling these faggot-wise round a platinum core and then fusing them together in the blowpipe.

In 1903 Heræus, in Germany, exhibited apparatus of fused quartz, made, I believe, by dropping rock crystal (previously heated above 600° C.) into an iridium tube furnace heated internally by oxyhydrogen flames, and working the product in the blowpipe.

Shenstone's method was developed commercially by Messrs. Johnson and Matthey, their organisation for this purpose being known as the Silica Syndicate. This company made notable improvements in the manufacture of transparent fusions. Kent's method of building up a bubble free fusion (Fig. 4) consisted in feeding rock crystal powder into the heated zone. The mass thus formed was subsequently worked in the O.H. blowpipe. (See Exhibits 1 in Fig. 1).

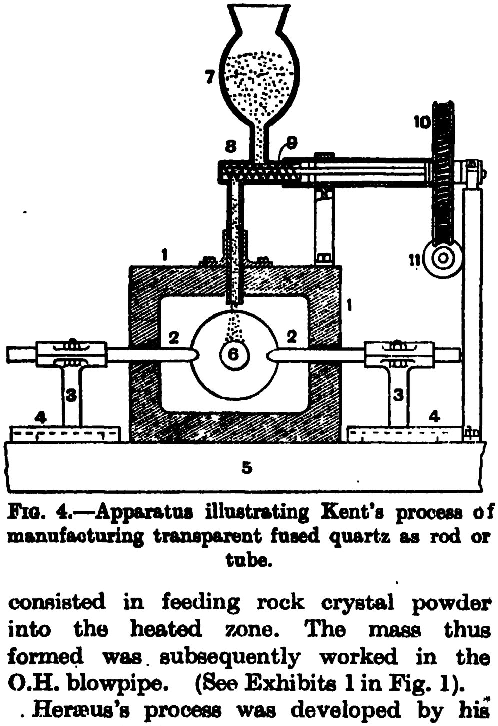

FIG. 4.—Apparatus illustrating Kent's process of manufacturing transparent fused quartz as rod or tube.

Heræus's process was developed by his firm, W. C. Heræus, of Hanau, which has continued to develop the use of transparent silica apparatus.

All these processes (except Sir Charles Parsons's) used rock crystal and produced a transparent glass-like product—more or less free from bubbles.

Complete freedom from bubbles is extremely difficult to attain owing to the fusion never becoming liquid. Subsequent research by Day and Shepherd showed that silica does not become liquid even when superheated at a pressure of 35 atmospheres.

Numerous proposals have been made to eliminate bubbles by fusing silica in vacuo, with or without a subsequent compression of the plastic fusion.

Thus, in 1904 and 5, Bredel, in Germany, patented a process of fusing in vacuo and allowing the fused mass to flow into an evacuated mold, or of fusing *from below* in an evacuated furnace.

In 1906 Wingrens, of Pasadena, Cal., patented a process of fusing in vacuo, and then subjecting the plastic fusion to gaseous pressure.

In the same year Day & Shepherd, of the Carnegie Institution, Washington, described the production of transparent silica plates by fusing rock crystal in an electrically-heated graphite box at 2,000° C., followed by further heating at 1,800° C, under a gaseous pressure of 500 lbs.

In 1907, Ludwig Bolle, in Germany, patented a process of silica fusion in a tubular furnace, the fusion being extruded by mechanical or gaseous pressure.

We now come to the fusion—on a larger scale—of pure silica sand. The inherent difficulty lies in the fact that, at the temperature of fusion, silica reacts with practically every known refractory material, except the refractory metals—platinum, iridium, etc., the cost of which is prohibitive, except for small scale operations.

In 1902 two important steps were taken. In the U.S.A. Elihu Thomson patented a method of forming articles of fused silica by a process similar to that of Sir C. Parsons, but working at atmospheric pressure. Thomson's heating core (Fig. 5) was of carbon or graphite and was so shaped as to form the mold or core for the ultimate product, *i.e.*, fusion round a rod produced a tube of silica—a basin-shaped heating core produced (or was intended to produce) a silica basin. The carbon core, surrounded by the sand to be fused, was electrically heated (the electrical data were not disclosed in the patents) until the sand in contact with the core was melted to the required thickness. The current was cut off, the fusion allowed to cool, and the fused mass mechanically separated from the cold core, or the core was burnt off by excess of oxygen.

In this country R. S. Hutton, of Owen's College, Manchester, who had previously worked with Moissan in France on the arc furnace, independently developed a very similar process.

Hutton formed silica tubes either by

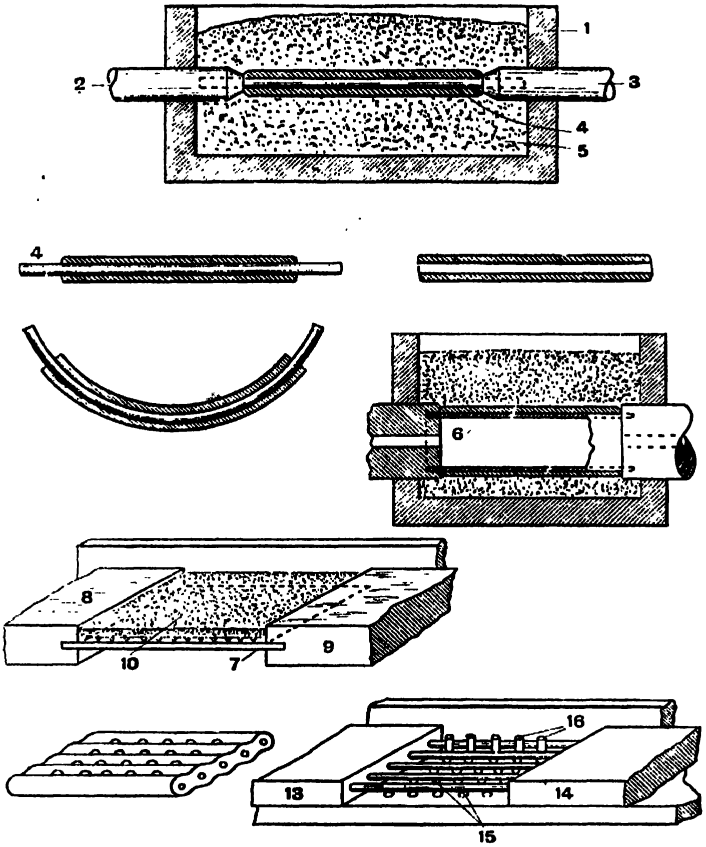

FIG. 5.—Elihu Thomson's process for manufacturing tubes, etc.

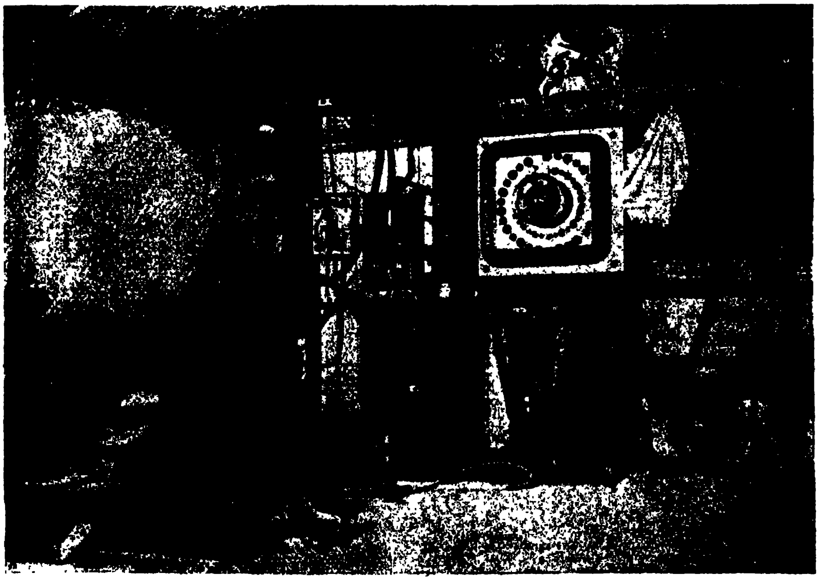

FIG. 6.—Furnace used by Dr. Bottomley in his early experiments.

passing a current through a carbon rod embedded in sand, or by supporting sand in a graphite trough having a graphite core fixed axially within it, and fusing the sand round the core by an electric arc arranged to travel longitudinally immediately above the trough. Threlfall, using Hutton's first method, made rough tubes up to 5″ and 6″ in diameter and (in one instance) up to 12 to 15 feet in length.

All these methods produce the same *new* material, namely, a fused silica of white slightly translucent appearance, like compressed snow, the colour and opacity being due to the large numbers of small air or gas bubbles disseminated throughout the mass. Both processes suffered from the disadvantage that the size and shape of the fusion were limited to those of the heating core, and that owing to the liability of silica to react with carbon—forming carborundum with evolution of carbon monoxide gas—the separation of the carbon core and production of a clean fusion were matters of much difficulty and uncertainty. A similar process to those of Thomson and Hutton was patented in Germany by Ruhsetradt in the same year. In all these processes it was essential to keep the temperature *as low as possible*, to avoid the reaction of silica and carbon.

About 1902 the present Lord Rayleigh (who is now, I am glad to say, associated with the Thermal Syndicate) showed me a small tube of fused silica, which he had made for some experiments on the critical temperature of mercury, and he described the interesting properties of the material.

As the result experiments were started at Wallsend, in 1903, with the object of developing, if possible, a commercial method of fusion by means of some form of electric furnace. The late Dr. J. Frank Bottomley was in charge of the experiments, with Mr. R. W. Clark as his electrical assistant. Messrs Merz and McLellan designed the electrical equipment, Mr. R. S. Hutton acted as consultant, and the present lecturer, so to speak, "also ran." After numerous failures, with both arc and resistance heating, an accidental result pointed the road to success.

The furnace (so to call it) consisted of a built-up brick or metal trough full of sand with a heating core fixed axially within it. (Fig. 6). Dr. Bottomley's note of the experiment explains what occurred:—

Fusion of sand with a rod of graphite as core.

The previous experiment was repeated with the difference that the core was composed of a single graphite rod between two 3″ carbons.

The current readings during the experiment were the following:—

start	9.59	1160 amps.	14 volts.	
	10.3	1175	14	
	10.20	1200	14	
	10.30	1400	16	current increased.
	10.33	1420	16	
	10.48	700	40	
	10.49	860	52	
	10.51	current broken.		

After 49 minutes heating the gas given off by the reaction between the quartz and silica burst through, and shortly afterwards the rod broke.

On opening up the furnace it was found that the fused sand has been blown out by the pressure of gas generated to a large egg shaped mass. The sand was well fused for about an ⅛″. The size of the piece was about 13″ long by 7″ diameter.

Here are the actual fusions produced by these experiments. (See Exhibit 1 of Fig. 2).

It soon became clear that by working at a much higher temperature than Thomson and Hutton, and by carefully regulating the temperature, it was possible not merely to bring the whole fusion to a state of substantially uniform plasticity, but also so to regulate the interior gaseous pressure (due to CO and silica vapour formation) that the fusion *remained separated from the core* except at the relatively cool extremities of the core. Under these conditions there was no further reaction between silica and carbon, and the fusion could be blown up in situ into molds surrounding the fusion.

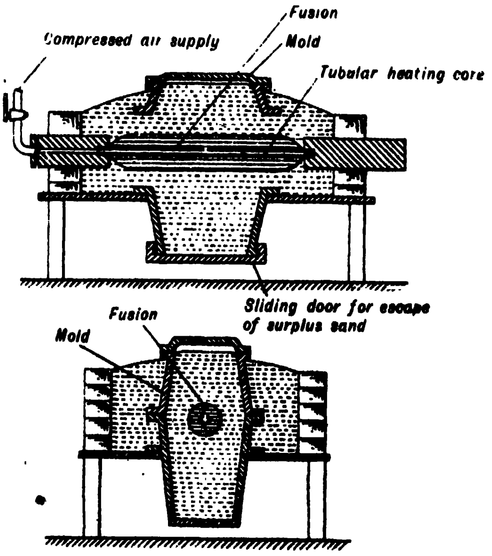

Fig. 7.

(Fig. 7). A little later it was found that the core could be withdrawn altogether from the fusion and the fusion itself removed from the furnace. (Fig. 8). Moreover, the fused mass—in the form of a large tubular sausage—was found to retain its plasticity for a considerable time, due, as we now know, to the heat insulating effects of the unfused sand which adheres to the fusion. In consequence of this, the fusion could be drawn into tubes or blown out into moulds (see Exhibit 3, Fig. 1) or pressed or rolled (see Exhibit 2, Fig. 1) *without reheating*.

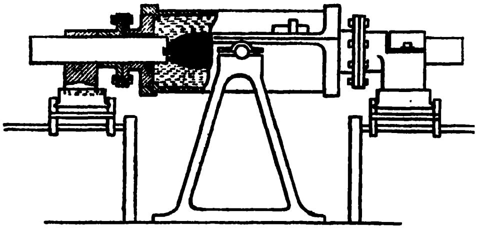

FIG. 8.—Horizontal furnace for fusion and removal of plastic mass for shaping after withdrawal of heating core (Bottomley and Paget's patent).

In the Thermal Syndicate's patents the working conditions are stated in terms of the current requirements for a specified size of heating core. Later researches by other workers have shown that the change from crystalline quartz to amorphous silica begins at 1470° C—that melting begins about 1,650°, and that the pasty condition is reached at between 1,750° and 1,800° C.

The material produced by drawing, blowing or pressing a sausage of fused silica sand differs from the products of Elihu Thomson and Hutton, in that the spherical bubbles of the former processes are drawn or spread out into threads or laminations, so that the material has a grain. This results in a characteristic change of appearance, as will be seen from the samples. The high lustre on the inside of blown fusions (see Exhibit 2, Fig. 2) has a practical use in the case of electric and gas-lighting bowls—it has also been used for mosaic work. (Exhibit 3, Fig. 2). The first important exhibition of vitreous silica ware or "Vitreosil" was made by the Thermal Syndicate at the Brussels Exhibition of 1910. These were, I believe, the only exhibits (except those of platinum shown by Johnson and Matthey) which survived the disastrous fire which destroyed the British Section. (Exhibit 4, Fig. 2). It was a good advertisement for the properties of fused silica, but (and I should like to emphasise this point) it was *not* the Thermal Syndicate who *lit* the fire!

One of the effects of this Exhibition was to stimulate certain German workers to imitate the processes described in the Thermal Syndicate's patents.

In particular Dr. Volker, between 1907 and 1910 developed a process in which the interior gaseous pressure for blowing the fusion into the mould was produced, not by introducing gas through a nozzle, but by dropping a slice of potato or other moisture-containing substance inside the fusion after withdrawing the heating rod and before closing it by mechanical pressure. The fusion was thus blown up by internal steam pressure.

In Germany and in England this process was held to be an infringement of the Thermal Syndicate's patents and was discontinued.

In 1917 the Thermal Syndicate and the Silica Syndicate became associated and the transparent silica works of the latter were transferred to the Thermal Syndicate's works at Wallsend-on-Tyne.

We will now consider very briefly the various physical properties of our material and see how these have been utilised in practice.

The first outstanding property of fused silica—whether transparent or opaque—is its low co-efficient of expansion. (Fig. 9).

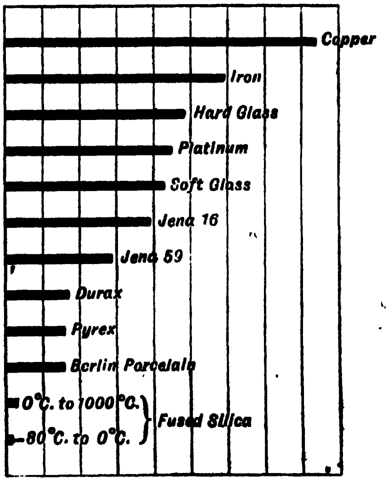

FIG. 9.—Chart comparing various co-efficients of expansion, drawn to proportional scale.

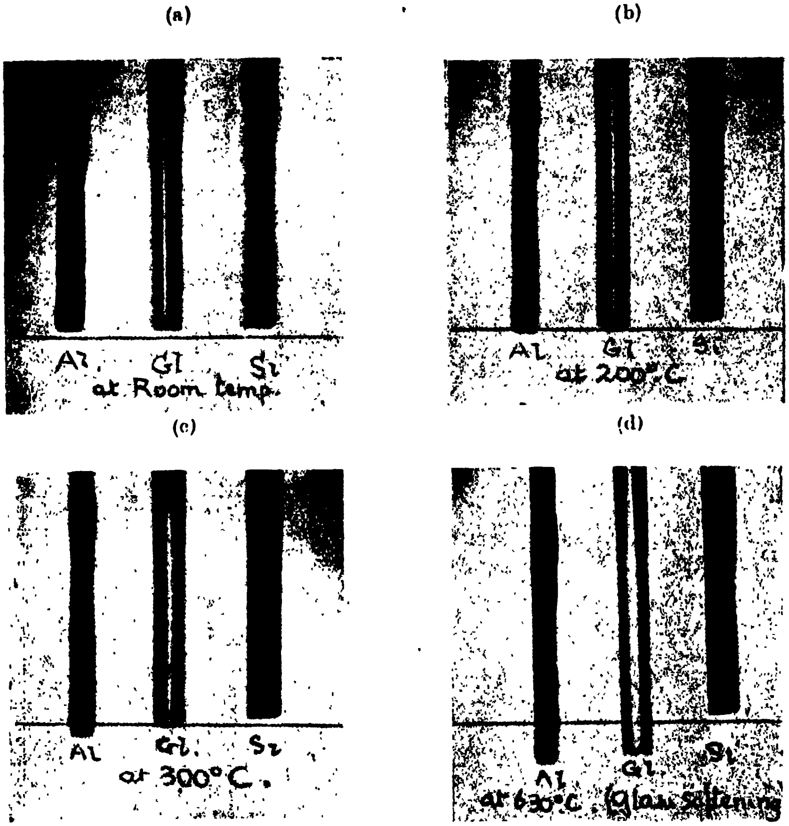
Fused silica is in a class by itself—its expansion being less than ⅙ of that of the best glass of the Pyrex type, and less than 1/20th of that of the high expansion glasses.

Dr. H. D. H. Drane, the Research Chemical Engineer of the Thermal Syndicate, has devised an effective experiment to demonstrate the relative expansion of fused silica—ordinary laboratory glass and metallic aluminium. A tube of fused silica is surrounded by a coil of resistance wire, which can be electrically heated. Inside the tubular furnace thus formed are suspended a rod of fused silica, a rod of glass and a rod of aluminium, which at room temperature are of such a length as just to project beyond the mouth of the silica tube. The shadows of the rods are seen, inverted, on the screen. (Fig. 10).



(a) (b) (c) (d)

FIG. 10.

The current has now been turned on so as to heat up the silica tube and its contents. As the two rods are suspended from the top of the tube they will expand downwards and their inverted shadows will be seen to grow upwards.

As it will take some minutes for the tube to heat up, and as a watched pot never boils, we will get on with the lecture and return to our experiment in a few minutes.

The practical effect of the low co-efficient of expansion is that one part of a mass of fused silica may be chilled and the other heated without straining the material sufficiently to crack it.

Here, for example, are similar pieces of fused silica, Jena glass and Pyrex glass, which we will heat in a bunsen flame and dip into cold water.

In each case the material cracks—except the silica—which is not surprising, seeing that the Pyrex and Jena glasses expand from six to nine times more than the silica.

We will now return to the heated tube and rods. The glass and aluminium rods have grown appreciably in comparison with the silica. (Fig. 10). Eventually the glass will soften and draw out (at c. 620° C.) and the aluminium will melt (at 657° C.), while the silica rod still shows no appreciable lengthening.* An interesting application of this property of low expansion with increase of temperature is in the use of fused silica rods as standards of length—for example, as in the standard metre of the N.P.L.

---

* NOTE.—In the actual experiment the glass rod accidentally touched and became stuck to the silica rod! The illustrations, Fig. 10, are taken from a repetition of the experiment.

We may next take the *relating high softening point*, which is shown on the screen. (Fig. 11). This characteristic may be demonstrated by heating three rods of silica, Jena glass, and Pyrex glass, each clamped horizontally at one end by three bunsen flames. The glass rods soon soften and bend, while the silica rod remains rigid.

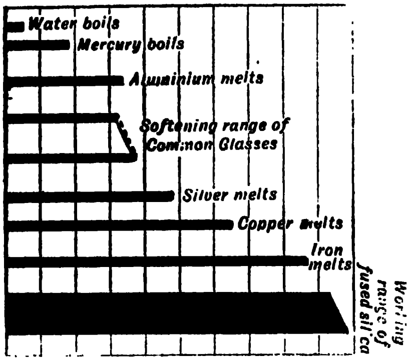


Fig. 11.—Chart comparing various fixed temperatures indicating high softening point of fused silica.

Practical uses of these properties appear in such apparatus as muffles, retorts, pyrometer tubes and roasting trays, besides combustion tubes for high temperature determination. (Exhibits 4, 5, Fig. 1.)

The next characteristic is an *undesirable* one—that of devitrification on prolonged heating. This is accompanied by a reduction in volume of 3 to 5%, and the vitreous mass changes to a biscuit-like substance with a greatly reduced mechanical strength, consisting of crystals of silica in the form of crystobalite or tridymite—according to the temperature, time and other conditions of heating.

Fortunately, the action only begins at relatively high temperatures. N.P.L. tests show that loss of strength, through devitrification hardly commences at 1,120° C., but is appreciable after four hours' continuous heating at 1,140° C. Above this temperature continuous heating gradually converts vitreous silica into crystobalite. Heated continuously for *eight days* at 800° C. in the presence of a suitable catalyst, such as KCl. and LiCl, vitreous silica is converted into tridymite.

For some of the above and for certain other data in this lecture, I am indebted to the paper of Professor Georges Flusin, of Grenoble, in Chimie et Industrie, of June, 1920, which gives a valuable summary of the crystallography and other physical and chemical characteristics of fused silica.

Pure fused silica devitrifies less than silica mixed with any known substances.

As to *mechanical properties*, the density of transparent fused silica is 2.21—that of the opaque variety being 2.07. Its hardness is of the same order as that of hard glass.

On Mohs' Scale—

Glass =4.2 to 6.2
Fused silica =4.9
Quartz =7.0 & 5.0 parallel to and perpendicular to the axis respectively.

In Kg. per mm² and for a sphere of 1 mm—

Fused silica =223.
French glass =130 to 265

Its modulus of elasticity measured in kg. per mm² is rather higher than Jena glass—6.6 as against 6.0. The crushing strength of fused silica is between that of granite and blue brick. Its tensile strength—when in the form of quartz fibres—is equal to that of high carbon spring steel. Its shear rigidity modulus, *i.e.*, the twisting force which, when applied to a cylindrical rod of unit length and diameter, twists the rod through unit angle—is slightly higher than that of crown glass.

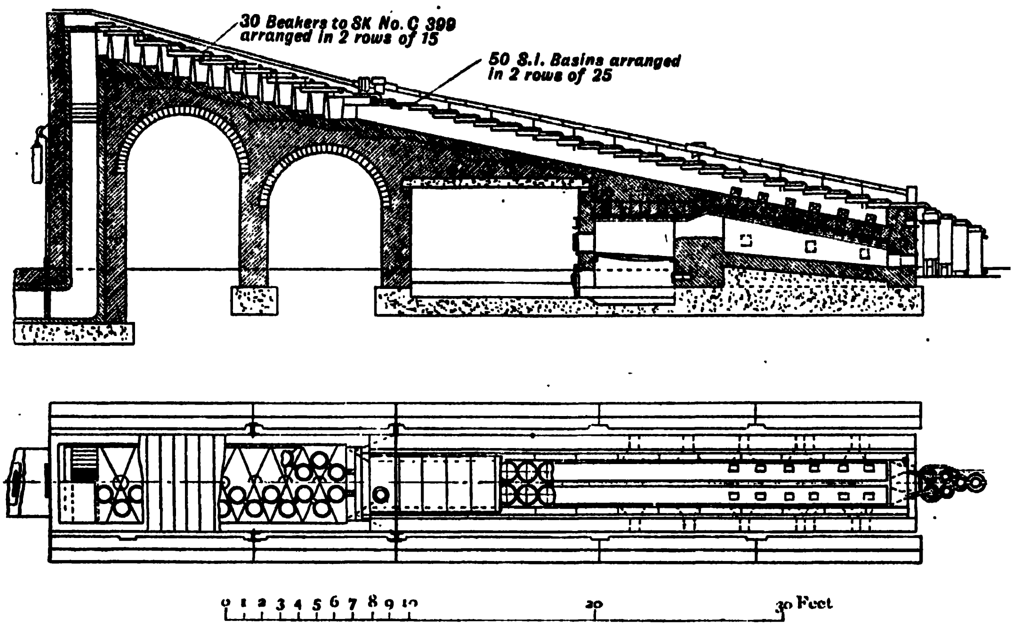
Crushing Strength.	tons per sq. inch.
Granite	10.5
Fused silica	7.0
Blue brick	3.0
Common brick	1 to 2
Silica brick	.75 to 5.0

The mechanical properties are summarised in the following table :—

Tensile strength (breaking).	tons per sq. inch.
High carbon spring steel ..	70
Quartz fibre	70
Glass (bulk)	0.2 to 0.6
Opaque fused silica (from bending tests)	2.2

Shear Rigidity Modulus.	dynes per Cm²	tons per sq. inch.
Copper ..	4 ×10¹¹	2.6×10³
Quartz fibre ..	3 ×10¹¹	2·×10³
Crown glass ..	2.9×10¹¹	1.9×10³
Flint glass ..	2.3×10¹¹	1.6×10³

On heating, fused silica becomes *more* resistant to shear up to about 1,000° C., being 7% higher at 850° than at normal room temperature. N.P.L. tests further



30 Beakers to SK No. C 399 arranged in 2 rows of 15
50 S.I. Basins arranged in 2 rows of 25
0 1 2 3 4 5 6 7 8 9 10 20 30 Feet

FIG. 12. - Plant used for concentration of sulphuric acid, showing pre-heating vessels, concentration basins, and coolers.

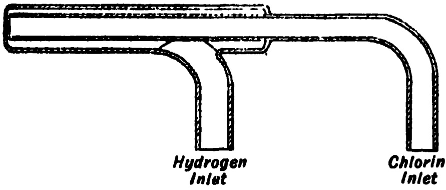


FIG. 13.—Silica burner used in the production of synthetic hydrochloric acid.

showed a permanent increase of strength after heating to $1,188^{c}$ for four hours and allowing the material to cool due to the release of internal strain produced by the rapid cooling of the material after shaping in the plastic state.

The heat conductivity of opaque fused silica is practically the same as that of glass - 0.002 c.g.s. units. Its specific heat is 0.202

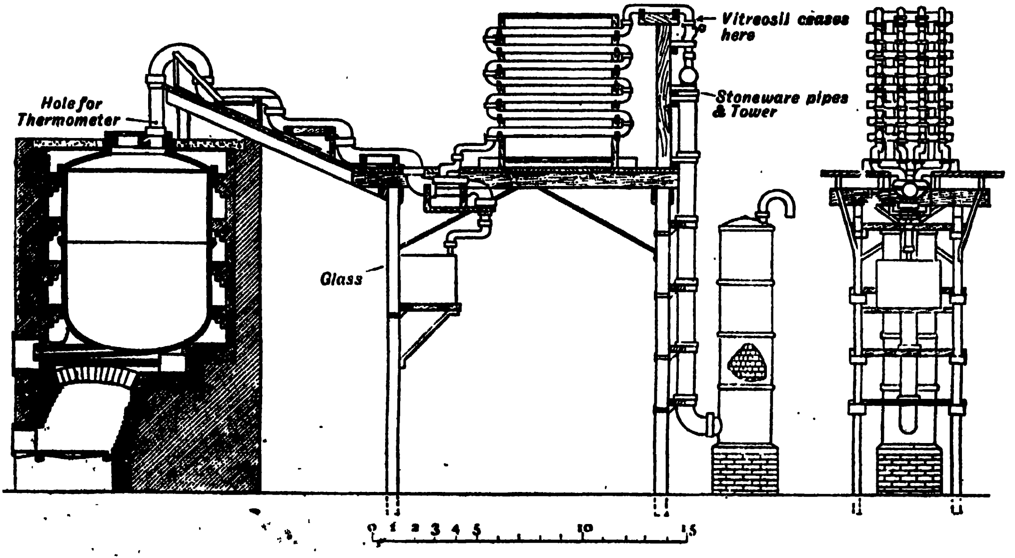

FIG. 14.—Nitric acid plant showing the use of fused silica for condensation unit.

at 100° C. and 0.290 at 1,000° C. In chemical properties the chief virtue of fused silica is its resistance to acids; its besetting sin is surrender to the alkalis and metallic oxides, with which it combines to form glasses.

As to acids, the material is entirely unaffected by any acids or mixtures of acids, except hydrofluoric (in which its solubility is 1/10 of that of glass) and concentrated phosphoric acid, in which it begins to dissolve appreciably at about 300° C.

Corrosion by H.F. . .	..
Glass	1,000
Fused silica	100
Quartz (parallel and perpendicular)	11 & 1

Here are two similar pieces of glass and fused silica, which we will dip into strong hydrofluoric acid for a few minutes. The result is that the glass rod becomes whitened by the formation of gelatinous silica, while the silica rod is quite unaffected.

Acid resistance makes fused silica the ideal material for the production of concentrated acids; indeed, at the beginning of the war there was, I believe, no other material immediately available in this country. All the rest came from Germany.

Figures 12, 13 and 14 show one or two typical plants utilising vitreosil for :-

H_2SO_4—Concentration,

H-Cl—Burner for synthetic production of Hydrochloric Acid,

HNO_3—Distillation, respectively.

In Fig. 1, exhibit 6 shows a tray for acid concentration, 7 a flue pipe, 7a a 9 foot socketed pipe, 8 an S type acid condenser, 9 an 18″ diameter bend, 10 and 11 distilling vessels, 12 is a pyrometer tube. In Fig. 2, 4a is a cooler for acid concentration, 4b is the centre pipe for 4a, through which hot acid enters, 5 is a 60 foot coil for acid condensation.

Fused silica is also *quite* insoluble in water at boiling point (which is not the case with glass), and in consequence the International Atomic Weight Commission recommended the use of silica vessels for analytical operations of high precision—except, of course, for the heating of alkaline and basic compounds. In this connection it must also be remembered that fused silica begins to volatilise below its softening point and that at temperatures above 1,350° C small losses by evaporation begin to appear.

Owing to its resistance to steam and to temperature changes, transparent fused silica tubes are used as gauge glasses for steam boilers. (Exhibit 13, Fig. 1).

There is increasing recognition of the importance, in refined chemical work of avoiding contamination by the traces of alkali, which even chemically resistant glass ware will part with to certain reagents and solutions. Many instances of changes in sensitive solutions kept in glass vessels have been traced to the alkali of the glass. The use of bottles, flasks, beakers, etc., of fused silica obviates the risk of such contamination and chemical change.

Another and, so far, a purely disadvantageous property of fused silica is its permeability to gases at high temperatures.

Helium begins to diffuse appreciably at 180° C., hydrogen at 300° C., nitrogen at 600° C. This action increases with rising temperature. The diffusion rates at 500° C. are in the ratio $He : H_2 = 22 : 1$; at 600° C. $H : N = 100 : 1$. According to Johnson and Burt, a well evacuated bulb one litre capacity and of wall-thickness 1.5 mm. may be kept in air at 400° C. for 100 hours before the internal pressure reaches 10^{-4} mm.—the gas which enters the bulb being mainly nitrogen.

Turning now to the electrical properties, the most interesting is the low conductivity of fused silica at high temperatures.

	At 15° C.	At 150° C.
Fused silica ..	$> 2 \times 10^8$	$> 2 \times 10^8$†
Jena glass.. ..	2×10^8	2×10^7†
Ordinary glass ..	5×10^5	1×10^5†
Porcelain ..	22×10^8	4×10^5

Though at ordinary atmospheric temperatures porcelain is considerably the better insulator, at 150° C. fused silica has 500 *times* the resistivity of porcelain.

The resistivity falls at higher temperatures thus :—

Temperature	230°C.	250	700	800
Resistivity in Megohms per c.m.^{3}	2×10^7	2.5×10^2	3×10^1	2×10^1

Fig. 15 shows the temperatures at which the resistances of various insulators become equal to 1 megohm per cm.^{3}*

Fused silica has the further advantage over porcelain and glass as an insulator of being *less hygroscopic*, so that surface leakage is reduced.

---

† See Campbell. Proc.Phys.Soc. 1913. 25. 336-7.

* NOTE.—These data as to conductivity are from tests of the U.S.A. Bureau of Standards taken during the war.

The *specific inductive capacity* is relatively low—being 3.5 to 3.6 as compared with 5.6 for mica and porcelain.

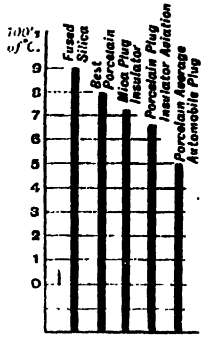

FIG. 15.—Chart showing temperature at which resistances of various insulators equal 1 megohm per cm. cube.

Vaseline	2.2
Fused silica	3.5 to 3.6
Sulphur..	4.0
Mica	ca5.6
Porcelain	ca5.6
Glass crown to flint	5.0 to 10

The *dielectric strength* of fused silica is equal to that of the best glass :—

	K.V. per c.m.
Commercial insulating oil ..	50—100
Glass	75—200
Fused silica	100—200

Fused silica has been successfully used as a high tension insulator for direct current in Cotrell precipitation plants for the treatment of flue gases, under conditions of heavy arcing which caused all other insulators to break down.

As to *optical* properties, fused silica is, when free from bubbles, very transparent to ultra violet radiations, visible light, and heat.

We have here a solid rod of fused silica 120 c.m. long, of which one end can be heated to whiteness in the O-H blowpipe. (See Fig. 16). The other end is thickened so as to form a rough lens. The light passes—apparently undiminished in intensity and unaltered in colour—through a thickness of 120 c.m., *i.e.*, nearly 4 feet of fused silica; it will be seen that though the rod is bent through three right angles the light is internally reflected and keeps within the rod. Even an appreciable amount of *heat* passes through a great thickness of fused silica as is shown by the movement of the light spot on the galvanometer scale, when a thermocouple is placed in the path of the emergent radiation at the cold end of a silica rod (but without a thickened end), and the other end of the rod is heated. In working short lengths of rod in the blowpipe the operator must take care not to burn his fingers in the radiant heat which emerges at the *cold* end of the rod!

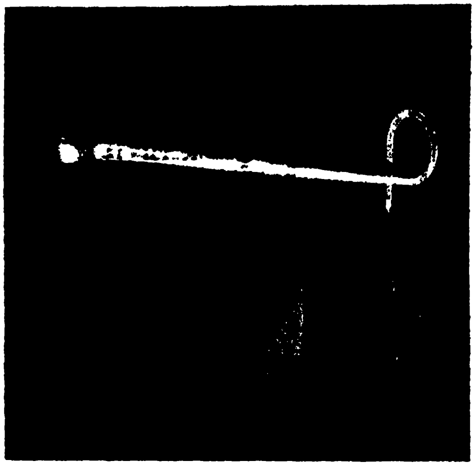

FIG. 16.—Transmission of light through silica rod.

The comparative transparency of fused silica to long wave-length radiation is shown in the following tables, which are due to Coblentz and Weniger in America.

	Thickness mm.	Source. Incandest. mantle 107 μ.	Hg.Arc. filtered through blackcard 310 μ.
Quartz ⊥ to axis	41.7	12.1%	58.9%
Fused quartz ..	2.0	12.5%	60.0%
Fluorite ..	.59	5.3%	42.2%
Glass ..	.18	2.1%	25.9%

Fig. 17 shows the relative transparencies of various substances to ultra violet radiation.

Fused silica is quite transparent to ultraviolet rays down to $\lambda = .226\ \mu$ to $.220\ \mu$, and to some extent down to $0.189\ \mu$, whereas the most transparent glasses are transparent only down to $\lambda = .298\ \mu$.

Here is a quartz mercury-vapour lamp giving visible and ultra-violet light.

The visible and invisible light pass through a screen, either of *glass* or of fused silica and any radiations which pass through fall on a zinc plate connected to a charged electroscope.

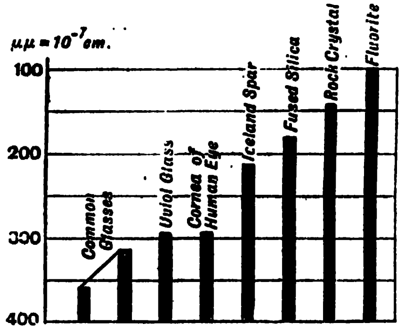

FIG. 17.—Chart showing relative transparencies of various substances to ultra-violet radiation.

The effect of ultra-violet light is, as is well known, to cause the charge to leak away by the discharge of electrons from the surface of a zinc plate, when negatively charged, so that the leaves of the electroscope fall together.

When the glass screen is interposed no leakage occurs. When the silica screen is substituted the leaves collapse rapidly, showing the great transparency of silica to the short wave radiations which discharge the electroscope.

The effect may be illustrated in another way, namely, by means of the chemical action of ultra-violet light on a solution of KI and starch, which is darkened by the chemical liberation of iodine in the solution.

Similar solutions in two vessels one of glass, the other of fused silica, are placed side by side in the beam of visible and ultra-violet light.

It will be seen that in a few minutes the solution in the silica vessel is appreciably darker than that in the glass—showing that the silica has allowed more of the chemically active rays to pass through into the solution.

For this reason fused silica mercury vapour lamps have been successfully used, especially in America, for the sterilisation of water and other liquids by the action of ultra-violet light.

The refractive index of fused silica for the D line is 1.4585.

So much for the optical properties of our material.

Besides the Thermal Syndicate and Silica Syndicate, there have been other workers in the field. The work of Dr. Volker, though put to an end in Germany, has reappeared in France and the U.S.A., but on a relatively small scale and so far, has not produced any distinctive products.

In U.S.A. the G.E.C. have in recent years carried on silica fusion at Lynn under Dr. Elihu Thomson, whose early work in 1902 has already been referred to.

A description of the products of these works is given in the *General Electric Review* for February of last year.

The most interesting technical advance by the G.E.C. is in the production of transparent rods and tubes by fusing rock crystal in vacuo in a tubular furnace and drawing the fused mass between water-cooled dies. Besides transparent ware, the G.E.C. have produced 6in. to 10in. molded insulators for H.T. work. It is curious that the writer of the G.E.C. article—which gives an historic résumé—is apparently ignorant of all the work which has been done in Europe since 1902. The G.E.C. is not usually 20 years behind the times!

Returning now to Thermal Syndicate products, the most important developments since the war have been in the manufacture of translucent globes for incandescent gas burners. These, though necessarily much more costly than glass, have proved so reliable that they are now very widely used. (See Exhibit 6, Fig. 2).

In these cases, as also in that of laboratory ware, the material is glazed on both sides by subsequent treatment, as distinct from the heavy chemical ware which is simply blown into a mold and has an external coating of unfused sand.

Another interesting development is the manufacture of large thermionic valves for W.T. work.

By the courtesy of the Admiralty and the Signal School, I am able to exhibit two valves of Signal School design, manufactured by the Mullard Radio Valve Co., of Balham, the fused silica parts being supplied by the Thermal Syndicate. (Exhibits 14 and 15, Fig. 1). The smaller valve is of 2.5 k.w., the larger of 10 k.w. output.

The T.22 type (10 k.w.) is that described by H. Morris-Airey, C.B.E., before the Inst.E.E. on March 7th, 1923. This valve has had considerable use. Exhibit 16 shows a still larger valve envelope 33" by 8" diameter.

The use of fused silica for laboratory ware is too well known to need further explanation.

By the courtesy of Messrs. Kelvin, Bottomley & Baird, I am able to show specimens of optical fused quartz made by the Thermal Syndicate and worked by them, also a series of silica-enveloped mercury vapour lamps and a very interesting silica enveloped gas-filled lamp.

Here we have a collection of typical pieces of heavy chemical ware. At the beginning of this lecture I showed one of the first blown-out fusions produced at Wallsend in January, 1904. We have here a comparable fusion blown for the occasion of this lecture—20 years later. (See Exhibit 7, Fig. 2). This "flask" weighs 130 lbs. and has a capacity of 770 litres or 170 gallons.

Unlike the patience of this audience, the technical uses of fused silica are far from being exhausted. There are surely many new and useful applications lying in wait for those who have the wit to realise them.

I venture the hope that in another 20 years' time we may all be here to meet again and see the results of fresh technical advances as great in comparison as those which I have had the honour of demonstrating this evening.

APPENDIX.

LIST OF EXHIBITS.

	Fig.	Ref. No.
Specimens of Rock Crystal, "geyserite" sand, pure quartz sand	—	—
Fulgurites from Maldonado, and from Griqualand, South Africa	—	—
Tube of fused rock crystal made by Shenstone's method	—	—
Collection of transparent laboratory ware	1	1
Tube made by Hutton (resistance heated rod)	—	—
"Ostrich egg" fusion made January, 1904	2	1
First fusion blown by air pressure, 1904	—	—
First fusion blown into a mold, June, 1904—basin of 4 litres capacity	—	—
Early dome-shaped muffle, 12" x 6"	—	—
Sausage-shaped fusion, before manipulation	—	—
Section of sausage-shaped fusion	—	—
Trough 4' 6" long x 4" x 4", produced by rolling plastic fusion	1	2
Cluster of 170 small crucibles blown into mold	1	3
18" basin showing lustrous inner surface	2	2
Specimen of mosaic	2	3
Crucible 8" x 5¾" from the Brussels Exhibition fire	2	4
Large threaded tube for electric muffle 6' x 8" diam.	1	4
Small threaded tube for electric muffle 8" x 1" diam.	1	4
Type of small ignition dish in commercial use, 1907 2" diam.	—	—
Collection of opaque Vitreosil laboratory ware—crucibles, beakers, ignition trays, etc.	1	5
Specimens of devitrified silica	—	—
Large tray for acid concentration, 3' 4" x 1' 5" x 6½"	1	6
Flue pipe or drain for corrosive fluids	1	7
9' Socketed close-ended pipe	1	7a
S type bend acid condenser, 6' 6" centres	1	8
Socketed right-angled bend tube, 18" diam.		1
Distilling vessel closed top. 2' 5" x 1' 7" dia.	1	10
Luted top distilling vessel, 2' 3" x 1' 8" dia.	1	11
Cooler pot for concentrated acids	2	4a
Centre pipe for sulphuric acid cooler pot	2	4b
Tube used for pyrometer observation in Kilns, etc., 4½" diam. x 3'	1	12
Boiler gauge glasses of transparent silica, 1' 6" x ¾" ext.	1	13
Collection of Vitreosil gloves for incandescent gas burners	2	6
First inner and outer glazed tubing produced, about 1" x 6"	—	—
W.T. Valves 2.5 K.W.	1	14
10 K.W.	1	15
32" x 8" envelope	1	16
Optical fused quartz, worked by Messrs. Kelvin Bottomley & Baird	—	—
Silica enveloped mercury vapour lamps (Thermal Syndicate, Ltd., and Kelvin Bottomley & Baird)	—	—
Silica enveloped gas-filled lamp (Thermal Syndicate, Ltd., and Kelvin Bottomley and Baird)	—	—
Flask-shaped vessel, 170 gallons capacity	1	7

DISCUSSION.

The Hon. Sir Charles A. Parsons, K.C.B., F.R.S., said that in 1887 he carried out some experiments in which silica sand was fused by means of an electrically-heated carbon rod. It was quite unintentionally on his part, while he was investigating some other problem, that he came upon the possibility of fusing silica in this way. His object was to make hard carbon rods which, by this treatment, were increased in density from 1.6 S.G. to 2.4, and it was hoped would last longer in arc lamps of his firm, and not to make fused silica. But having succeeded in fusing silica he communicated the results to the Royal Society. He must say that he shared the author's astonishment at the statement of the early work on this subject which appeared in the *General Electric Review*, and he would like to suggest that when the author's paper was published in the Journal, 100 copies should be sent to Dr. Elihu Thomson for his enlightenment. He thought that the Society should be very much indebted to the author that evening for giving the first full and unreserved explanation of the manufacture and use of fused silica.

Sir Robert Hadfield, Bt., D.Sc., F.R.S., said that the chief thing he had to mention about the paper was that they were all greatly indebted to the valuable work done by the Thermal Syndicate Company at Wallsend. Fused silica had proved to be a very valuable property in the laboratories of which his own firm had control. They had avoided breakages and other disagreeable results by using this product. A gentleman in the audience whom he was glad to see was Mr. Darling, who, he thought, was one of the first to call attention to this very valuable product. He was very glad to hear Sir Charles Parsons's remarks that evening, and his reference to America was, he thought, quite in order. It was not uncommon for people to imagine that no work had been done on a particular subject outside their own country. The Germans were rather fond of taking certain things and claiming them to be entirely their own. In one of the leading technical journals issued that week he noticed a reference to a book published in Germany, in which the author suggested that Germany had introduced all the improvements in iron and steel! They might take that for what it was worth. He himself came from Sheffield, where they were very much indebted to silica. Had it not been for the presence of a certain siliceous compound in the neighbourhood of that city, it was very probable that Sir Henry Bessemer would never have carried his wonderful process to the success that he did. Bessemer was hindered in his early work by the fact that the linings of his converters, being made of destructible material, melted away, but he came down to Sheffield where they had this valuable deposit of ganister, which was a very pure form of silica, and with this as the material for his lining he achieved great success. In Sheffield, therefore, they had good reason to be indebted to the valuable material called silica. He remembered speaking to Sir Henry Bessemer, who told him how much he was indebted to the Sheffield deposits. The speaker was sure that there were many experts present who knew far more about the matter than he did himself, and he would only thank the author warmly for a valuable paper.

PROFESSOR C. V. BOYS, F.R.S., wished to join in expressing his very great pleasure at the paper. As the author had explained to them, it was not the first time that he (the speaker) had seen fused silica, but it was the first time that he had realised how many wonderful things, such as were exhibited that evening as if they were quite common stuff, were made. He would not put before the Society any work of his own, except to say that it was 37 years ago that, in drawing his quartz fibres,[1] he worked with silica in the purest form he could obtain, rock crystal, and he recognised, even at that time, its wonderful properties.[2] Only by working with pure optical quartz out of contact with any other body could he get the clear transparent fused rods with which he made the quartz fibres. He might tell the author how he made a quartz tube which he showed at the meeting of the British Association in Leeds.[3] The author had described the placing of parallel rods around a core, but he (the speaker) made his tube by taking a rod and melting it and winding it around nothing at all. He kept on doing so until at last he got a tube. Having made that tube hot with the oxy-hydrogen blow-pipe, which alone he had to use, he drew it out into a finer tube, and from this made the clear transparent bulb which he showed at Leeds. He said at the time that that was the forerunner of greater things, and in that respect he thought he was a good prophet. He had been a little surprised at one remark which had fallen from the author, about porcelain being a better insulator than fused quartz. He would like to know whether the fused quartz to which the author had referred was a really pure quartz, or whether impurity of any sort had been allowed to come upon it. He had made experiments upon the conductivity or insulating properties of fused silica[4] as follows:—He took a rod made of pure lead glass, drawn out, and put it into an atmosphere kept dry by sulphuric acid. From it a pair of gold leaves of an electroscope were suspended, charged, and the rate at which they fell together denoted the rate at which the electricity escaped. He noted the result when a rod of the purest lead glass was used in air chemically dried by sulphuric acid. Then he took a corresponding rod of fused quartz. This he dipped into water and put it into a box in which water was liberally sprinkled so that the air was saturated, and he found that the rate at which the gold leaves came together, and at which the electricity escaped, was the same under these conditions as before. In other words, the experiment showed the conductivity of the air, the rods by comparison being perfect insulators. As this was the case, he could not understand how anything could be found to be a better insulator than really pure fused quartz. In conclusion, he could never have imagined, working on the small scale of 37 years ago, that he would live to see such things as he saw there that evening, and it was a great pleasure to him to see them.

DR. R. S. HUTTON desired to point out that the paper did not quite do justice to the work which the author himself had done. Sir Richard Paget was one of the few to realise the possible industrial developments and applications of this material. Quite in the early days—as far back as 1902—the author had been interested in the work of other people on this subject, and wrote him to the effect that he wanted to look round and discover what were the possibilities of the industrial manufacture. The speaker felt perfectly convinced, knowing as he did, something of the early history of the subject, that had it not been for Sir Richard Paget's foresight at that time, they might be now in the same position as the General Electric Company apparently imagined the English work to be. He would like to say also that with regard to Professor Elihu Thomson's article, to which he had had his attention drawn some few months ago, he was astounded to find how Professor Thomson had stated the course of events. He happened to have a very good opportunity of understanding Pro-

4.—*Phil. Mag.* July, 1889.

fessor Thomson's position with regard to fused quartz in the year 1902. In that year the speaker read his first note on the electric fusion of quartz before the Manchester Philosophical Society, and later in that year he went over to the United States and read another paper on the subject before the American Electro-Chemical Society. At that meeting, Dr. W. R. Whitney, who was now head of the General Electrical Research Department, came to him and mentioned that Professor Elihu Thomson had been working on quartz, and had suggested that he should visit him. The speaker had the habit in those days of keeping a diary, and, recently, after his attention had been drawn to the article in the G.E.C. Review, he looked up two passages written in his diary during his American visit, according to which he had not been at all impressed by the work which was done at that time in America. All that the speaker would claim was that Professor Thomson's work and ideas had not in any way contributed to his own results, nor to the subsequent English developments based thereon.

The investigations of Professor Thomson and himself were quite independent of one another, but so far as the resistance method of heating was concerned, both had apparently been forestalled by the earlier work of Sir Charles Parsons.

There was one other point to be mentioned. The author in his paper gave a picture of one of the first experiments, and showed the MSS. giving an account of the subject in the writing of the late Dr. Bottomley. If the experiment referred to was the one which he himself remembered very well, it was carried out on a certain Saturday morning when they were all working very much against time. They had taken off their coats and were shovelling something like a ton of sand, or, at least, many hundredweights, in order to build a rough furnace to a height of probably 4 ft. or 4 ft. 6 ins. from the floor. After they had completed their work and turned on the current, they were appalled to see the whole mass of this material rise up before them. They sat down and almost wept with disappointment, but before they had gone very far in their despair, they realised that, through an accident, they had found the secret of working the quartz. Up to that time they had gradually succeeded in softening and melting it, but the circumstance just described gave them the real clue to the mass working of the material. This probably was the actual experiment to which the author had referred. At any rate it was very vivid in his recollection. It was one of those experimental disappointments which, as so often happened, pointed the way to a greater success, and the success in this case had been wonderfully exploited by the Thermal Syndicate.

Mr. Charles R. Darling added his thanks to those of previous speakers for the splendid description of the making of vitrified silica which appeared in the paper. Formerly there was a certain amount of mystery about the process, and he was glad that the lecturer had "taken the lid off" completely. The secret things, as Sir Robert Hadfield once said, were never any advantage. It was always better to let people know the secrets of a process, unless, of course, to do so was attended by the liability to some financial loss. After the paper of that evening they would be able to see clearly exactly how this material was made. He could not claim to have had anything to do with the early making of silica, but he could claim to have been a pioneer with regard to the use of it. He was one of the first to use silica tubes for simple electrical resistance furnaces. He was at that time working with pyrometers and using resistance furnaces with porcelain tubes. If one switched on a strong current suddenly the tubes always cracked, and one was always having to renew the tubes. The moment silica tubes were made he procured them, and he found them stand up to the conditions almost indefinitely. He told others of his experience and published it in various quarters, and now silica was the material used all over the world in very large quantities in the electric tube furnace and muffle furnace. This was one little industry which had grown out of the production of vitrified silica. The author had stated that if the vitrified silica were heated continuously for eight days at 800° C., the whole of the vitreous silica was converted into tridymite. The speaker's own experience was that one could use it not for eight days, but for eight months, provided that one did not get metallic oxide impurities. He thought that the statement in the paper, if left unqualified, would lead to misunderstanding. The fact was that vitrified silica might be used under these conditions almost indefinitely, but if the metallic oxide were incorporated it caused fluxing, and that was the weak point in the use of silica. He asked whether anything had been done with zirconia, whether there was any prospect of making zirconia tubes on these lines, because zirconia was not attacked by most of these metallic oxides. The whole subject reminded one that it was not always the chemical composition which mattered, but the physical condition was often of much greater importance. The fusing of silica—bringing it into a condition in which it was rarely found in nature, and then only accidentally—made all the difference in its properties; the heat treatment of this material brought about profound changes, and, no doubt, research with other minerals would show similar changes.

The Chairman (Sir Herbert Jackson) said that the Society was to be congratulated on having had this exceptional paper. The author had given them a very clear picture of the whole subject. He confessed that he was amazed as he looked round the room and saw the various articles exhibited, especially the "flask," which the author had exhibited at the end of his paper. It was only lately that the usefulness of fused silica had been really recognised. He himself spoke with the utmost gratitude for the work of the pioneers, for to-day there were many laboratory and industrial processes which it would be almost impossible to carry out without silica apparatus. Not only was silica of use in many respects, but it also added, as they would appreciate from the exhibits, a touch of beauty in many directions. He felt confident that there was a great artistic future for this product. Taking up a number of small exhibits of bowls and the like, he asked the audience to notice how beautiful they were when worked in this translucent material. In glass dishes certain kinds of cooked food looked very ugly and unappetising, but when the dishes were made of translucent silica, there would be a beauty about the appearance which clear glass could not rival. He would not take up the time of the audience much further, because he knew that the members were eager to make a closer inspection of the articles which the author had brought to illustrate his paper, but he wished to express their indebtedness to Dr. Drane, the Research Chemist of the Thermal Syndicate, who had assisted Sir Richard Paget in his lecture. He knew that Dr. Drane was hard at work on some most interesting researches, and he was looking forward to another paper which would deal with the further developments now in a commencing stage. It had been a great pleasure to hear at first hand an account of this wonderful process, and he asked the audience to offer to Sir Richard Paget a very hearty vote of thanks for a remarkable and interesting lecture.

Sir Richard Paget, in reply, said that Sir Herbert Jackson had been altogether too appreciative; but that was just like him, and he supposed he could not help it.

With regard to the question asked by Professor Boys about the conductivity of silica, what he had said in his paper was not an observation of his own, but he had taken the results from a series got out by the U.S. Bureau of Standards in connection with their tests for various insulators. He was glad to hear from Professor Boys that the case for fused silica at ordinary temperature was so much better than he had been led to suppose.

Dr. Hutton's account of the original experiment was, of course, to be preferred to his own, because Dr. Hutton was present on that memorable occasion and the speaker was not. He had no doubt that the experiment was exactly as Dr. Hutton had described it, and very likely the type of furnace used for that experiment was not actually the one he had shown on the screen.

With regard to Mr. Darling's question as to the possibility of using zirconia, experiments had been made in fusing zirconia, but he was afraid that this line of research was fruitless, because zirconia had quite a high efficiency of expansion and tended to crack on cooling. It failed to arrive at the stage of plasticity like silica, though, of course, it might be used as an aggregated material.

The vote of thanks was then accorded unanimously.

LA VIE INDUSTRIELLE EN FRANCE.

Nouvelles Automobiles à Gazogène.

Des essais ont été faits dans divers pays, depuis assez longtemps déjà, pour actionner des automobiles au moyen de gazogènes, mais les applications industrielles de ce système ont été peu nombreuses jusqu'ici. Cependant, il y a deux ans, l'Automobile-Club de France a institué un concours de véhicules à gaz pauvre, qui a donné des résultats vraiment intéressants: six véhicules ont fonctionné normalement pendant un mois; celui qui fut classé premier était de construction anglaise, mais presque tous ont présenté les qualités nécessaires pour un fonctionnement industriel normal.

Depuis lors, l'intérêt très grand qu'il y a pour la France à réduire sa consommation d'essence, a conduit d'autres constructeurs à étudier la question. Ainsi, la Maison Berliet de Lyon, vient de construire deux véhicules: un camion et une voiture de tourisme, actionnés par un nouveau type de gazogène à charbon de bois. Ce gazogène, du système Imbert, est formé d'une simple caisse en tôle mince, sans revêtement réfractaire, dont la section verticale est trapézoïdale. A la base se trouvent deux tuyères se faisant face, par lesquelles l'air pénètre sous l'influence de l'aspiration du moteur. Entre ces deux tuyères, il se trouve une zone de combustion à très haute température, au centre de la masse de charbon de bois. Grâce à cette température très élevée, il ne se forme que de l'oxyde de carbone; la zone de combustion étant localisée au centre du gazogène, les parois ne sort pas très chaudes, et on a pu éviter l'emploi d'un revêtement réfractaire: aussi, le gazogène ne pèse pas plus qu'un réservoir d'essence. Les cendres sont fondues et tombent à la base de l'appareil. Dans la voiture de tourisme, le gazogène est placé à l'arrière, et l'aspect de la carosserie n'est guère différent d'une carosserie ordinaire.

Le gaz traverse le charbon, puis passe dans des chambres tubulaires en tôle disposées sur les côtés, où il se refroidit. Il traverse ensuite un cylindre dépoussiéreur, rempli de limaille imbibée d'huile. Avant son arrivée aux cylindres, il se mélange, enfin, au moyen d'un robinet, à la proportion d'air nécessaire.

La Distribution de Chaleur par Centrales Thermiques

dans les Groupes d'Immeubles, à Paris.

Depuis la guerre, la construction des maisons d'habitation dans les grandes villes, et principalement à Paris, est presque entièrement suspendue, à cause de l'augmentation du prix des matériaux et de la main d'oeuvre. Quelques vastes entreprises ont été, cependant, organisées depuis peu, mais elles ont adopté une formule nouvelle. Elles construisent de vastes groupes d'immeubles

divisés en nombreux appartements qui sont, non pas loués, mais vendus de 30,000 à 200,000 francs, aux personnes qui désirent les habiter. Celles-ci deviennent ainsi propriétaires de la partie de l'immeuble qu'elles habitent, et elles paient annuellement une somme représentant simplement l'entretien et les services communs, tels que le chauffage.

Cette combinaison a permis l'édification de groupes d'immeubles très importants, dans lesquels on a pu appliquer pour la première fois le système de distribution de chaleur à partir d'une station centrale. Ce système avait reçu jusqu'ici surtout des applications en Amérique, mais n'avait pas encore été employé en France.

Un groupe de 17 grands immeubles à 7 étages, actuellement en construction, à Paris, doit être chauffé par une centrale thermique unique. La puissance horaire de l'installation est de 1,485,000 calories (5,900,00 B.T.U. environ). Le chauffage est assuré par des radiateurs à eau chaude, au nombre de 1150 ; les plus éloignés de la chaufferie en sont à une distance de 350 mètres (382 yards). La circulation d'eau chaude est forcée au moyen d'une pompe centrifuge, actionné par une turbine à vapeur à basse pression. L'eau est chauffée dans 8 chaudières. On estime que ce système permet de réaliser une économie de plus de 25% par rapport à la dépense qu'aurait nécessité le chauffage indépendant de chaque maison.

VIADUC EN BÉTON ARMÉ, A ARCS DE 190 MÈTRES (625 FEET) SUR L'ELORN, A PLOUGASTEL, PRÈS DE BREST.

On va bientôt construire un viaduc monumental en béton armé sur l'embouchure de l'Elorn, entre Brest et Plougastel - Daoulas. Cet estuaire présente une largeur de 700 mètres et le programme imposait de réserver une passe navigable de 70 mètres, avec une hauteur de 36 mètres dans la partie centrale. L'ouvrage doit supporter la chaussée d'une route et permettre, en outre, l'installation ultérieure d'un chemin de fer à voie normale.

Le projet adopté comporte trois grands arcs de 190 mètres (environ 625 feet) de portée chacun prenant appui sur deux piles en rivière, et surmontés d'un double tablier, le tablier supérieur portant la route et le tablier inférieur la voie ferrée. L'ouvrage est prolongé de chaque côté par deux viaducs d'accès, distincts pour le chemin de fer et pour la route ; sa longueur totale est supérieure à 800 mètres.

Le double tablier offre de grands avantages. Au point de vue de la circulation sur la route, ils sont évidents : la chaussée reste entièrement libre et tout risque d'accident est écarté. Au point de vue esthétique, le double tablier permet d'obtenir une puissante membrure horizontale supérieure, de dimensions en harmonie avec les proportions générales de l'ouvrage. Au point de vue construction, ce système fournit une poutre très rigide, capable de se porter sur de grandes longueurs, ce qui permet de réduire au minimum le nombre de supports verticaux.

La principale difficulté vient des circonstances locales qui interdisent, pour l'établissement du cintre, l'emploi de points d'appui intermédiaires entre les piles et culées. Cette difficulté sera résolue par l'emploi d'un cintre retroussé analogue à celui qui a été employé pour la construction des hangars à dirigeables d'Orly, près Paris, et qui franchira d'un seul jet l'espace libre entre les retombées des voûtes.

Les quantités de matériaux à mettre en oeuvre sont supérieures à 20.000 mètres cubes pour le béton et à 1.200 tonnes pour l'acier.

LA FABRICATION DES TUYAUX EN CIMENT ARMÉ, PAR CENTRIFUGATION.

Les tuyaux en ciment, armé ou non, sont très employés, en raison de leur prix peu élevé et de leur forte résistance. Si certaines précautions sont prises, on peut aussi les rendre étanches ; cependant, par un simple pilonnage à la main, on obtient difficilement une étanchéité suffisante, et on ne peut guère descendre au-dessous de 30 centimètres de diamètre. Par centrifugation, au contraire, on peut obtenir une meilleure étanchéité et fabriquer en toutes dimensions. Cette fabrication s'est développée récemment en France, notamment au moyen du procédé Caron, exploité par la Société des Tuyaux et Agglomérés centrifugés, qui possède plusieurs usines en France.

Dans un moule cylindrique horizontal, on introduit une quantité déterminée de béton de ciment gâché assez clair ; on l'étale en remuant simplement le moule à la main ; puis on fait tourner pendant trois minutes ; on laisse prendre pendant 24 heures, à une température d'environ 20° ; on démoule : on laisse durcir pendant trois ou quatre jours à l'abri du soleil ; on laisse ensuite les tuyaux au parc pendant deux mois avant de les mettre en usage.

Les joints longitudinaux du moule pourraient laisser échapper, par leurs fentes, le mortier fin de ciment, ce qui créerait, tout le long du tuyau, deux zones de faible résistance. M. Caron vite ceci en enroulant à l'intérieur du moule une feuille de caoutchouc qui enveloppe le béton et empêche toute fuite du ciment.

La fabrication des tuyaux armés est tout aussi simple. On place l'armature dans le moule, avant d'y introduire le béton, et on opère ensuite comme pour le tuyau non armé.

CORRESPONDENCE.

◆

NEW USES FOR RUBBER.

With reference to the above paper published in the *Journal* of March 14th, I consider that rubber blocks for road paving should be three times as long as ordinary wood blocks and have twice the width of the thickness, and also should have "ribbed" faces parallel to the sides of the pavement.

These blocks in my opinion, would not twist, and would prevent side-slipping.

It is evident that with the heavy motor traffic of to-day, rubber blocks do *not* eliminate noise.

D. R. Broadbent,
A.M.I.E.E., A.M.I.M.E.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings at 8 o'clock.

April 9.—Frank Hope-Jones, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum." Professor C. Vernon Boys, F.R.S., will preside.

April 30.—Brigadier-General Sir Henry Maybury, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "The London Dock District and its Roads."

May 5 (Monday).—T. Thorne Baker, "Photography in Industry, Science and Medicine."

May 7.—J. Robinson, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation." Admiral of the Fleet Sir Henry Jackson, G.C.B., K.C.V.O., F.R.S., will preside.

May 14.—

May 21.—(Trueman Wood Lecture.) Sir William J. Pope, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, "The Outlook in Chemistry."

May 28.—Mrs. Arthur McGarth (Rosita Forbes), "The Position of the Arabs in Art and Literature." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Indian Section.

Friday afternoons, at 4.30 o'clock:—

May 2.—Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced:—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

Dominions and Colonies Section.

Tuesday, May 27, at 4.30 o'clock.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Wednesday, June 4, at 4.30 o'clock.—The Rt. Hon. Sir Frederick Lugard, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates."

Monday, June 16, at 4.30 o'clock.—C. V. Corless, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada."

Cobb Lectures.

Monday evenings, at 8 o'clock:—

Dr. T. Slater Price, Director of Research, British Photographic Research Association, "Certain Fundamental Problems in Photography." Three Lectures. March 24, 31; April 7.

Lecture III: April 7.—Photohalides and the visible image. Sensitising action of silver ions. Latent image. Duplication of light action by chemical agents. Silver halide grain as the unit. Sensitive centres on the grains. Nucleus exposure. Nature of the sensitive centres.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, April 7 ... Geographical Society, 135, New Bond Street, W., 8.30 p.m. Captain P. K. Boulnois, "On the Western Frontier of the Sudan."

Surveyors' Institution, 12, Great George street, S.W., 8 p.m.

Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 5.30 p.m. Mr. H. A. Watson, "Organisation of Traffic and Locomotive Departments in relation to Running."

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Prof. F. C. Roget, "The Influence of Calvin down the Centuries on the Religious and Political Development of the Protestant Nations."

Chemical Industry, Society of (London Section), at the Royal Institution, Albemarle Street, W., 8 p.m. Prof. Armstrong, "Sir James Dewar as an Experimental Inquirer."

Royal Institution, Albemarle Street, W., 5 p.m. General meeting.

Engineers, Society of, at the Geological Society, Burlington House, Piccadilly, W. 5.30 p.m. Mr. A. C. Ionides, "Gas-Firing (Flame Control)."

Tuesday, April 8 ... Petroleum Technologists, Institution of, at the Royal Society of Arts, John Street, Adelphi, W.C. 5.30 p.m. Mr. W. J. Wilson, "The Crude Oil of Burma and Assam."

Royal Institution, Albemarle Street W., 5.15 p.m. Sir I. Gollancz, "Some other Aspects of 14th Century Poetry." (Lecture II.)

Metals, Institute of (Local Sections), Armstrong College, Newcastle-on-Tyne, 7.30 p.m. Annual general meeting, Chamber of Commerce, New Street, Birmingham. 7 p.m., annual general meeting.

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. P. J. Higgs, "Observation Notes on a 20,000 ton Ship with Oil Engines and Electric Propulsion."

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Dr. J. H. Hutton, "The Use of Stone in the Naga Hills."

Central Asian Society, at the Royal United Service Institution, Whitehall, S.W., 5 p.m.

Photographic Society, 35, Russell Square, W.C., 7 p.m. Messrs. K. C. D. Hickman and D. A. Spencer, "The Washing of Photographic Products." (Parts III. and IV.)

Chadwick Public Lecture, at the Royal Society of Medicine, 1, Wimpole Street, W., 5.15 p.m. Dr. C. Porter, "American Public Health from an English Point of View."

WEDNESDAY, APRIL 9 ... Meteorological Society, 49, Cromwell Road, S.W., 5 p.m. 1. Mr. I. D. Margary, "Glaisher Stand *versus* Stevenson Screen. A comparison of 40 years' observations of maximum and minimum temperature as recorded in both screens at Camden Square, London." 2. Mr. R. Hill, "A lens for whole sky photographs." 3. Mr. F. J. W. Whipple, "The significance of regression equations in the analysis of upper air observations."

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m.

Naval Architects, Institution of, at the Royal United Service Institution, Whitehall, S.W., 11 a.m. Annual meeting. 1.—Address by the President, the Duke of Northumberland. 2.—Admiral of the Fleet, Sir Doveton Sturdee, Strategical and Tactical Considerations governing Warship Design."

THURSDAY, APRIL 10 .. Pottery and Glass Trades Benevolent Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.45 p.m. Mr. P. W. V. Brooks, "Helpful Hints to Salefolk."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Royal Institution, Albemarle Street, W., 5.15 p.m. Dr. E. J. Allen, "Scientific Research on Sea Fisheries." (Lecture II.)

Metals, Institute of, at the Institute of Marine Engineers, 85, The Minories, E., 8 p.m. Dr. G. H. Gulliver, "Failures in Metals and Alloys."

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Dr. T. P. Nunn, "The Philosophy of Gentile."

Naval Architects, Institution of, at the Royal United Service Institution, Whitehall, S.W. Annual meeting continued. 11 a.m.:—1. Mr. A. Hurd, "The Future of Sea Transport." 2, Commander C. D. Burney, "Development of the Airship, with special reference to Transport." 3. Sir Alfred Read, "Sea-borne Coastal Trade." 3 p.m.:—1, M. P. Payne, "Results of some rolling experiments on Ship Models." 2, Professor K. Suyehiro, "The Drift of Ships caused by rolling among Waves." 8 p.m.:—1, Mr. R. W. Allen, "Application of Steam Turbines to Auxiliary Machinery." 2, Messrs. F. G. Martin and A. T. Wall, "High Elastic Limit Mild Steel and its General Applications."

Historical Society, 22, Russell Square, W.C., 5 p.m. Miss I. Wright, "The English Expedition against St. Domingo (1655) from Spanish Official Records."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Annual General Meeting.

Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. Mr. S. C. Bartholomew, "Power Circuit Interference with Telegraphs and Telephones."

Mechanical Engineers, Institution of, (South Wales Section), at the South Wales Institute of Engineers, Cardiff. Mr. J. P. Udal, "Payments by Results." (Graduates' Section, N.W. Branch), Engineers' Club, Albert Square, Manchester, 7.15 p.m. Mr. F. W. L. Heathcote, "Involute Gears."

FRIDAY, APRIL 11 London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Mr. J. Slater, "The Strand and the Adelphi."

Cyclists' Touring Club, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.30 p.m. Annual General Meeting.

Naval Architects, Institution of, at the Royal United Service Institution, Whitehall, S.W. Annual meeting continued. 11 a.m.:—1, Eng.-Commander R. Beeman, "Further Experimental Work on Diesel Engines." 2, Mr. H. W. Nicholls, "Vibration of Ships." 3. Mr. G. Vedeler, "The Torsion of Ships." 3 p.m.:—1, Mr. J. L. Kent, "The Effect of Wind and Waves on the Propulsion of Ships." 2, Dr. T. E. Stanton and Miss D. Marshall, "The Effect of Length on the Skin Friction of Flat Surfaces." 3, Mr. A. Shigemitsu, "Skin Friction Resistance and the Law of Comparison." 4, Mr. J. Tutin, "The Analysis of Ship Resistance."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Dr. T. Moss, "The Relationship of Air-Consumption to Brake Horse-Power in Internal Combustion Engines; Road and Flight Tests."
(Midland Branch), Chamber of Commerce, New Street, Birmingham, 7.30 p.m. Mr. R. A. R. Cole, "The Manufacture of Chilled Iron Rolls."

Aeronautical Engineers, Institution of, at the Engineers' Club, Coventry Street, W., 6.30 p.m. Mr. S. M. Viale, "Radial Engines for Aircraft."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Annual General Meeting.

Royal Institution, Albemarle Street, W., 9 p.m. Prof. J. Thorpe, "Colours, Stains and Dyes."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. J. H. Vickers, "The Photography of Wild Birds and Animals."

Metals, Institute of, The University, St. George's Square, Sheffield, 7.30 p.m. Annual General Meeting. Mrs. A. Vellan and Prof. Desch, "The Protection of Aluminium by Electro-Plating."

Physical Society, at the Imperial College of Science, South Kensington, S.W., 5 p.m.

Malacological Society, at the Linnean Society, Burlington House, Piccadilly, W., 8 p.m.

Astronomical Society, Burlington House, Piccadilly, W., 5 p.m.

Medical Officers of Health, Society of, 1, Upper Montague Street, W.C., 5 p.m. Dr. G. H. Miles, "Industrial Psychology and the Public Health."

SATURDAY, APRIL 12 .. Royal Institution, Albemarle Street, W., 3 p.m. Dr. C. Singer, "Leonardo da Vinci as a Man of Science."

Journal of the Royal Society of Arts.

10 MAY 1924

FRIDAY, APRIL 11, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

TRUEMAN WOOD LECTURE.

In consequence of illness, PROFESSOR C. VERNON BOYS, F.R.S., will be unable to deliver the Trueman Wood Lecture on "Calorimetry," which he had arranged to give on WEDNESDAY, MAY 21st. His place will be taken by SIR WILLIAM J. POPE, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, who has chosen as his subject, "The Outlook in Chemistry."

SEVENTEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 2nd, 1924; LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Aisinman, Dr. Semion, Paris, France.
Crichton, Alexander, New Brunswick, Canada.
Fazul, Mehr Ali, L.C.E., A.M.I.E., Hyderabad, Deccan, India.
Fern, William G., London and South Africa.
Mepham, George S., St. Louis, Missouri, U.S.A.
Miolée, Willem Frederik, Bulawayo, South Africa.
Moll, Thomas, Bedford.
Parsons, Frederick, Massachusetts, U.S.A.
Robertson, James Alexander, O.B.E., J.P., Cleveleys, via Blackpool.
Rusk, Professor Rogers D., M.A., B.S., Naperville, Illinois, U.S.A.

The following candidates were duly elected Fellows of the Society:—

Agnew, Andrew, C.B.E., London.
Anderson, Percy, M.B.E., Gerrard's Cross, Bucks.
Lundie, John, D.Sc., New York City, U.S.A.
O'Brien, Arthur Matthew, F.C.S., Skewen, Glam.
Parker, Charles, Nottingham.
Summers, Daniel Henry, Portsmouth.
Verma, Banwari Lall, Delhi, India.

A paper on "London Traffic" was read by SIR LYNDEN MACASSEY, K.B.E., LL.D., D.Sc. (Secretary to the Royal Commission on London Traffic, 1903-7).

The paper and discussion will be published in a subsequent number of the *Journal.*

EXTRA MEETING.

FRIDAY, APRIL 4th, 1924; HIS EXCELLENCY THE BRAZILIAN AMBASSADOR in the Chair.

A paper on "The Amazon Valley and its Development" was read by MR. GEORGE MACAULAY BOOTH, Director of the Bank of England and of the Booth Steamship Company, Ltd.

The paper and discussion will be printed in a subsequent number of the *Journal.*

A hundred copies of "Modern Brazil," by William Howarth, have been placed at the disposal of the Society by the publishers, Messrs. C. Tinling and Co., Ltd., Liverpool. Fellows of the Society who desire to receive free copies of the book are invited to apply to the Secretary.

COBB LECTURE.

MONDAY EVENING, APRIL 7th, 1924; DR. T. SLATER PRICE, Director of Research, British Photographic Research Association, delivered the third and final lecture of his course on "Certain Fundamental Problems in Photography."

On the motion of the CHAIRMAN, Sir HERBERT JACKSON, K.B.E., F.R.S., a vote of thanks was accorded to DR. SLATER PRICE for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

VISIT TO THE GUILDHALL.

On behalf of the Fellows of the Society and their ladies, the Council have gratefully accepted an invitation from Mr. H. G. Downer, LL.B., a member of the Common Council, to inspect the Guildhall, including the Art Gallery of the Corporation of London, on Thursday, May 8th, at 2.30 p.m.

Sir Alfred George Temple, F.S.A., will act as escort in the Art Gallery and Mr. Deputy Alderton, C.C., in the Council

Chamber, Crypt and other places of interest in the Guildhall.

Fellows desirous of availing themselves of the invitation should inform the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2, on or before May 3rd, mentioning the number of their party.

Those attending are requested to assemble at the main entrance to the Guildhall in King Street, Cheapside, at 2.30 p.m.

PROCEEDINGS OF THE SOCIETY.

THIRTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 5TH, 1924.

LORD ASKWITH, K.C.B., K.C., D.C.L., (Chairman of the Council), in the Chair.

THE CHAIRMAN said he had to introduce Sir Fabian Ware, Vice-President of the War Graves Commission, of which the Prince of Wales was the President. He had received a letter from the Private Secretary to Mr. Walsh in which he said: "The Secretary of State for War asks me to convey to you his very sincere regret at being unable to accept the kind invitation of the Council of the Royal Society of Arts to attend the lecture by Sir Fabian Ware to-night." The Minister of Transport, Mr. Harry Gosling, who was a member of the Commission, had also personally expressed to him his deep regret that he was prevented from attending the discourse, which he had particularly desired to do. Sir Fabian Ware, with others of the Royal Commission, had devoted six years of strenuous work to the graves of the fallen, known and unknown, in all parts of the world. Many of the audience might have visited the graves of those who were buried within a near distance of this country, at Etaples, Ypres, and particularly the beautiful cemetery at Terlincthum, near Boulogne. Some might have been led there by the various tours which had been organised by the Y.M.C.A. (of whose work he knew something himself, as he was Vice-President of it), by St. Barnabas Hostels, and by other organisations. There were, however, many unknown places of which Sir Fabian Ware would be able to speak that night in that great chain of graves almost girdling the world. Sir Fabian had but lately returned from Gallipoli, and his account would probably be most interesting of what was being done there, and of the various alterations in the general designs which might be made there, and also in places so far afield as China and East Africa. He would also be able to speak not only of the graves of known persons, and the artistic architecture or engineering work which had been done upon them, but also of the monuments which had been put up to those who had died as unknown warriors.

The following paper was read:—

BUILDING AND DECORATION OF THE WAR CEMETERIES.

By MAJOR-GENERAL SIR FABIAN WARE, K.C.V.O., K.B.E., C.M.G., C.B.

(Vice-Chairman, Imperial War Graves Commission).

The subject of my lecture is one on which it is extremely difficult to speak in public, and hitherto I have avoided doing so; but I felt when you invited me that the atmosphere provided by your Society and, if an old friend will allow me to say so, the sympathetic guidance which I know that Lord Askwith's chairmanship would ensure, made the undertaking at least possible.

Those of us who literally live and move among these dead cannot discuss their graves with that calm objectivity which art and science bring to bear, for instance, on the tomb of an ancient king, whose racial and religious prejudices have become faint for us in the great distances of time. These dead are of our own blood and race, or of one of the races which are united under the same king; their religion, whether our own or not, found expression in their patience and their sacrifice, which are still very present to our minds. Their religion and their racial characteristics are sacred and living things, and present generations will judge our work, and more particularly that of the architects who have designed the War Cemeteries, by the extent to which we have recognised this. These are difficult things to discuss; it is much easier to try to give expression to them in our work so that they may be intelligible to future generations, and may stir their imaginations and sanctify for them the memory of these dead. Allowing for the inevitable restraint under which he spoke, this is the thought, I think, underlying the words of one of our great architects who was describing to me his impressions when he first visited the cemeteries during the war: "Future generations," he said, "will find it difficult to realise the psychological conditions of those days, when one carried on from day to day at an emotional pitch never likely to be forgotten by those who went through it. The first conclusion I came to was, that whatever we did should speak unmistakeably to posterity of those tremendous days, and should speak in the language of to-day."

But before dealing with the work of the architects, let me say a few words about that of the engineers, recognising he division of labour between the architect and the engineer, a division which, I imagine, every rue artist deplores, but which is one of the many forms of specialisation brought about by the complications of modern civilisation, and which this country was, I believe, one of the first to impose. The engineer is sometimes regarded as the materialistic partner in this division; whether that is so or not, in this work he has had to bring his most sternly practical qualities to bear on a problem which is certainly of the idealist order; for as you may remember in 1917, at a period in the War when faith alone foretold victory, the representatives of the self-governing Dominions and of all parts of the British Empire met in London as an Imperial War Conference. The Prince of Wales, who had taken an active interest in our work at the front, then addressed to them a memorandum suggesting that they, representing the whole Empire, should make arrangements for the future care of war graves. The Conference unanimously agreed among other things, that, as far as was humanly possible, these graves should be permanent. Perpetuity in sepulture has in the past been a very rare thing, much rarer than is generally realised, assured in any degree to the great of the earth only, most commonly in this country by burial in some historical and sacred monument, of which Westminster Abbey, St. Paul's and other cathedrals immediately occur to us as examples. These dead, the Imperial War Conference held, certainly deserved the honour which had been shown in this way to the former great of the earth, and as they could not be brought in their hundreds of thousands (the British Empire gave over one-million dead to the cause for which she fought) beneath the sacred shelter of existing monuments, structures at least as lasting must be erected at the spots in distant lands where their comrades had buried them. To ensure this lasting quality, to give effect to this ideal of perpetuity, has been the special task of the engineer, with whom rests the last word on structural stability and durability. I shall naturally be speaking this evening a great deal more of the architects than of the engineers, but, believe me, nothing could have surpassed the devotion with which the highest possible mathematical and scientific knowledge has been placed at our disposal, and the invariable response of the engineers to the claims of a great ideal.

Let me give you one of the simplest examples of this. It is only necessary to visit any churchyard in this country to see how the headstones become displaced by time, sometimes leaning in all directions, at others removed and placed against a surrounding wall, the space they occupied being used for new burials or some other purpose. All chance of that had to be prevented in the war cemeteries, and this is what the engineers have done. A trench is dug at the back of each row and a continuous concrete beam is constructed in this. On the upper side of this beam there are sockets into which the headstones are fitted and fixed with cement, and they are thus held as in a vice, permanently immovable. The land for the cemeteries has, as you know, been given in perpetuity in each former allied country by the people of that country at their own cost, following the generous example first set by France in honour of our dead. There is, therefore, no fear that the land will ever be used for any other purpose, but even if that had not been so, the labour and expense which would be incurred in the removal of these headstones and their foundations, would economically prohibit anything of the kind.

You will have observed that the point of view from which I have approached the subject of the building and decoration of the war cemeteries has brought us directly to the graves themselves. And whatever line of thought you take this must inevitably be the result. But before I follow up this line, let me break off for one moment in order to give you some idea of the number and distribution of these graves over the face of the globe. I find that not only the general public, but even those who take a direct interest in the question, have very little conception of this. For instance, quite recently I received a letter from an important organisation asking if they were right in believing that there were several cemeteries with different names in the Ypres area. I think the best way I can bring the facts before you is by means of maps, on which the cemeteries are marked. You see them stretching across France and Belgium in a chain from the English Channel to the Vosges, nearly 1,000 of our War cemeteries in these two countries, in addition to more than 1,500 French Communal cemeteries and churchyards, in which some of our dead are buried. In Switzerland there is one cemetery at Vevey, where the remains of the British prisoners of war who died in that country have been gathered together. The chain continues across the north of Italy, and there are in that country, together with scattered cemeteries and graveyards, 93 in all. Across Macedonia the chain stretches—here there are 21 cemeteries—down the Gallipoli Peninsula,, where there are 31, to Smyrna, through Syria, where there are two, through Palestine, passing over the Mount of Olives itself—in Palestine there are 40—through Egypt, where there are 5, down Mesopotamia and to East Africa, where there are 400 burial places which it is necessary to concentrate, then the chain extends across the north of India, to China, where there is a cemetery at Tsingtao, and 23 other scattered burial grounds, to Australia and New Zealand, across Canada, and back to the United Kingdom, where there are more than 67,000 graves in some 5,000 churchyards and cemeteries. There are fifty other countries, off the track I have followed, where British War graves have been found. Someone, writing on these graves shortly after the war, truly said that the Empire had thrown a girdle of honour round the world.

You may ask why we have not moved all the small cemeteries into the larger ones. There are several reasons of which I will only mention one. During the war we chose certain authorised sites, where the dead could be buried, some of them close to the trenches; the soldiers were promised that if they brought their dead comrades to these, which they not unfrequently did at the risk of their lives, they would rest there permanently undisturbed.

With that necessary digression let me return to my subject. I said that from whatever point of view you approached it, you were led directly to the graves themselves. This is as it should be. Our work itself would indeed be a lamentable failure if, in designing the cemeteries, the graves had not always been first in our thoughts, if, for instance, the cemeteries were so ornate and elaborate in construction that the graves were hidden or overshadowed by buildings and monuments, and the impression was given at that first glance, which invariably biases our judgment, that they were merely a minor feature in the architectural conception. The vision of peace, with its background of sublime tragedy, proceeds from the graves alone, and if the architectural design is in any way a worthy one, even the casual visitor on entering the gate should first be irresistibly attracted by the rows of headstones; they should invite, and, if necessary, compel his attention. That is certainly the effect that the architectural treatment which has been adopted invariably has on me personally, and on every one with whom I have visited the cemeteries. It is not until you have passed silently before the headstones, reading the inscriptions, eloquent in their very brevity, that you gradually become conscious that each of these groups of dead, whether small or great, (in some there are no more than forty graves, in a few over ten thousand) is a community knit together by bonds of fellowship as in no ordinary resting places of the dead, and instinctively you look around for some symbol of this unity. It is then that you turn to the massive Stone of Remembrance and the Great Cross of Sacrifice.

Before considering these two collective monuments and other buildings which complete the construction, I will, therefore, describe first the headstones which mark the graves (and of which about 180,000 have already been erected to replace the wooden crosses). May I explain at the outset that I am speaking now of the very great majority of cemeteries? Those demanding exceptional treatment, owing to their peculiar situation or the race and religion of those buried in them, I will deal with subsequently.

The headstones are all of the same shape, two feet eight inches high (above the ground), one foot three inches broad, and three inches thick, the top forming a segment of a circle two feet six inches in radius. The size, proportions and upper curve were decided by a special Committee of artists and architects, as from both the æsthetic and practical point of view it was necessary to obtain the best opinion available. For instance, the durability of these stones depends largely on the effectiveness of the curve at the top to throw off the rain in the way least likely to wear the inscription. The curve designed has been found to give the maximum efficiency in this respect. On each headstone is inscribed a reproduction, specially designed for carving on stone, of the badge which the dead soldier wore in his cap. Should the grave be that of a general or an officer of higher rank, who did not wear his regimental badge, it is nevertheless the one which, by universal desire, is inscribed on his headstone. The name, age, military rank and other distinguishing details are engraved on the upper part of the stone,. in the middle a cross or other appropriate religious emblem, (e.g. the six pointed Star of David for a soldier of the Jewish faith) and below this a text or other personal tribute chosen by the relatives. One headstone, which is, alas, too common, is that to the unknown soldier bearing the words "Known unto God."

I am not to-night giving any account of the administrative side of the work, or I would have to draw your attention to the amount of correspondence involved in the making of every headstone, as, of course, the relatives' wishes have to be ascertained with regard to the religious emblem and the personal inscription at the foot of the headstone, and they have also to be asked to check and often to correct the initials and spelling of the name. The manufacture of these headstones is going on in all parts of Great Britain, the output being about 2,000 a week.

To turn now to the collective monuments: ". . . . a carven stone and a stark sword brooding on the bosom of the Cross," as Mr. Kipling described them in his poem on the King's Pilgrimage two years ago. In all the cemeteries there is the Great Cross of Sacrifice, designed by one of our principal architects, Sir Reginald Blomfield. It differs in size to suit the dimensions of the cemetery, the largest being twenty-four feet high, the smallest fourteen. It stands on a great octagonal block (weighing in the largest type about two tons), which rests on three octagonal steps. The shaft and arms are in section in the form of an octagon. The length of the two arms is about one-third of the height of the cross measured from the base of the shaft. The shaft is in one stone from the pedestal block to under the arms. The arms are in one piece of stone fastened by two bronze dowels in to the head of the shaft. The base of the shaft is let into the pedestal block by a six inch stone joggle and a bronze dowel. The shaft tapers from the base to the top of the vertical lines, being set out to a somewhat emphasised entasis.

There is no doubt that the design of this Cross, carried out in white stone, against which the bronze sword stands out in the changing lights, very much as old arms and weapons against a wall, has appealed very strongly to public imagination. Its symbolism, like that of many great artistic creations, is somewhat vague, or rather open to various interpretations; to some the sword is itself the cross and the stonework merely the frame, to others the sword symbolises the offering up in sacrifice of those who perished by the sword, and other interpretations suggest themselves, evidently many, for all who accept the Cross at all seem to have found in it something which responds to their individual feelings. You will see that it is indeed a noble monument, towering with a certain majesty above the headstones.

It was originally the intention of the Commission that each architect should be at liberty to design a special cross suitable in his view to each cemetery, but general opinion was too strong for us, and this design had been adopted wherever possible. We even recently had the design for the cemetery on the Mount of Olives modified, so that this cross should also be erected there. The thoughts which that suggests are better left to the imagination than put into words. As time has gone on the names "Cross of Sacrifice" and "Stone of Remembrance" have attached themselves to the two central monuments; I don't know who originated them, but they have been generally adopted, and undoubtedly express the feelings which each suggests, but it would not be right that this should in any way limit the use to which they are put. For instance, in a service which I attended last Easter in the large cemetery at Lijssenthoek, where 800 relatives had gathered together, Communion was celebrated at the stone, which was used as an altar.

This Stone of Remembrance, designed by Sir Edwin Lutyens, is to be found in all the larger cemeteries. Its dimensions are such as to make it a monument as permanent as any work of man can be. It is a monolith weighing nearly ten tons. Each stone bears the inscription engraven in large letters, "Their name liveth for evermore." I will describe it in Sir Edwin's own words—"Great fair stone of fine proportions, twelve feet in length, lying raised upon three steps, of which the first and third are twice the width of the second. . . . absolute and simple in form, with the greatest possible amount of labour and thought required in its manufacture, in that all its horizontal surfaces and planes are spherical and parts of parallel spheres, 1801 feet 8 inches in diameter, and all its vertical lines converging upwards to a point some 1801 feet 8 inches above the centre of these spheres."

The æsthetic effect of these two monuments depends on their setting in relation to the levels and surrounding natural features; each cemetery is therefore designed by a member of the Commission's architectural staff on the spot, under the guidance of one of the principal architects, by whom the design is finally approved. That was the system which Sir Frederic Kenyon recommended to the Commission in his report, which has guided us throughout our work. It is a form of collaboration between younger architects and the heads of their profession of which we may hear more in the future.

Personally, I always feel that the most restful effect is obtained where the cemetery contains no other stonework than the headstones and these two monuments, the whole drawn together and softened by trees and shrubs. I will show you examples of this. You will notice that some years must yet pass before the trees are large enough to have their full effect, and what is missing altogether from these photographs is the colour of the flowers, to which the cemeteries owe their chief beauty from early Spring to late Autumn. The horticultural aspect of our work has been dealt with in lectures by Dr. Hill, the Director of Kew Gardens, who has been helping us for the last six years. It certainly deserves a lecture to itself. The skill and devotion of our large staff of gardeners, all of them ex-service men, often with friends buried in the very cemetery they are tending, is beyond all praise. What an opportunity they have! White stones standing in green grass lawns, and these two white monuments for a background. Want of water, every possible variety of soil, sand dunes to be held back and covered with whatever growth they will take, some of the cemeteries in old orchards, others on the bleak hillside, with the worst possible aspect and no shelter from the weather, the natural desire of the Dominions that their own indigenous trees and shrubs should be planted near their graves, these and such considerations have called for many long and patient experiments. But here again the greatest skill and knowledge which the Empire possesses has been placed at our disposal, nurseries have been established which supply everything that is required from existing stock, and this part of the organisation is already beng transformed into the main branch of the permanent maintenance staff. The photographs will give some idea of what has already been achieved, but imagination must supply the colours of the flowers.

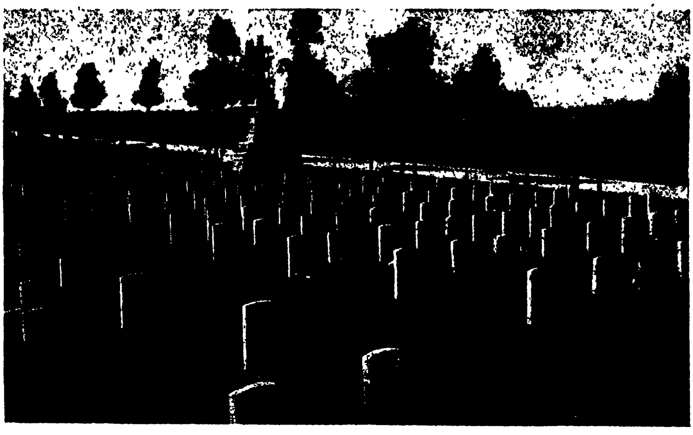

FIG. 1.—Ferme Olivier Military Cemetery, Belgium.

There are, however, larger cemeteries, some of them with ten or twelve thousand headstones the effect of which is to give an impression of barrenness, I might almost say desolation, however toned down with foliage and flowers, if they are not counterbalanced by further solid structures in addition to the Cross and the War Stone. In these shelters have been provided, and indeed, owing to the greater number of visitors who may be expected, the seclusion which they afford is very desirable. These give further scope to the architect. You have the simplest form, a shelter and gateway combined, at Forceville; at Terlincthun, near Boulogne, Mr. Herbert Baker has combined the shelter, to which he has added a Record House, and the War Stone on a broad terrace, the effect, with the Napoleon Column rising above the wood in the background, being very impressive. I wish I could also show you his beautiful treatment of the cemetery of Tyne Cot, on the Passchendaele ridge, where 11,000 soldiers, mostly unknown, lie around German blockhouses, the central one of which forms the base of the Cross of Sacrifice, and on the rising ground behind a shelter and record house are joined by a curved wall, on which are inscribed the names of 20,000 of those who have no known graves. But it is not yet completed. At Boulogne Eastern Cemetery, Mr. Charles Holden has connected the shelter and record house with a stone roof with a cornice supported on four columns. The stone of Remembrance is placed under this roof.

There is one cemetery in France which will be seen by more people than any other; it lies among the sand dunes at Etaples, close to the main line to Paris and the South, and 11,000 of our soldiers are buried here. The design was entrusted to Sir Edwin Lutyens. On the highest sand hill among the fir trees a wide terrace has been built overlooking the whole cemetery, and with a view of the English Channel in the distance. between the two light houses at Le Touquet. Above the centre of the terrace stands the Cross of Sacrifice, and below, on the terrace itself, the Stone of Remembrance. At each end of the terrace are pylons in the form of vaulted shelters, carrying overhead cenotaphs adorned with the flags of the several services. A stepped mound from the terrace gives access to the graves, which stretch in all directions, the headstones

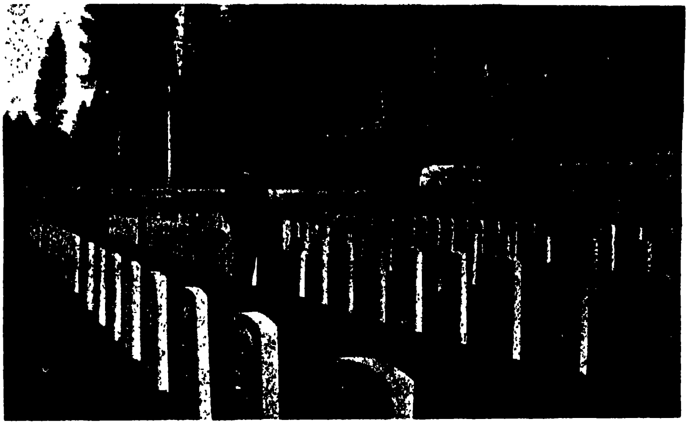

FIG. 2.—Boscon Military Cemetery, Italy.

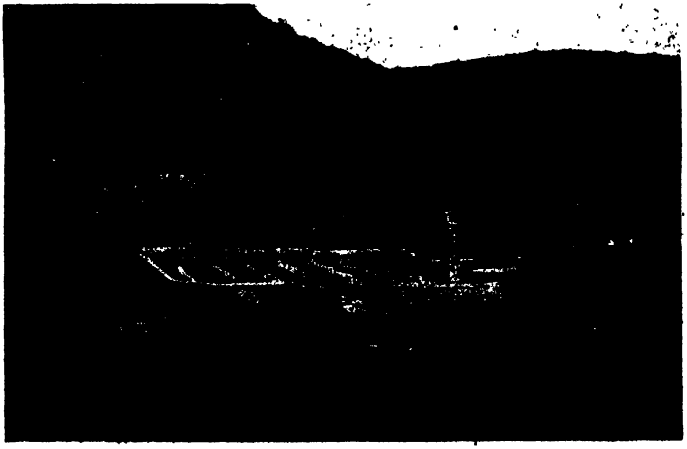

FIG. 3.—Cavalletto Military Cemetery, Italy.

stand in grass, and amidst them are growing trees and shrubs and flowers.

Throughout all these cemeteries you will have observed there are common features which give them their distinctive character. The Cross of Sacrifice stands out distinct in all of them, and as time goes on it is acquiring a special significance and association with the War Graves of the British Empire, so much so, that as I have said, the Commission has insisted on its employment wherever possible. But there are instances, even in mainly Christian cemeteries, where it is obviously unsuitable. This was first found to be so in the mountain cemeteries in Italy. You have seen with what effect Sir Robert Lorimer used it in the Giavera Cemetery in the Italian plains. On the Asiago Plateau, however, 4,000 feet high, covered with snow from October to April, are five small cemeteries, Monte Cavalletto, Granezza, Magnaboschi, lying among the open hills, Boscon and Barenthal in the clearings of a pine forest. These, as you will see from the photographs, are enclosed, according to Sir Robert's design, by walls built thick and strong of local marble, and in each is a massive cross formed of rough blocks of the same stone, sometimes white, sometimes red. There are no paths, but the headstones, of the same type as in France, rise from green sward in which are planted cyclamen, gentian, columbine, and the other exquisite wild flowers of the district, rock plants growing on the walls.

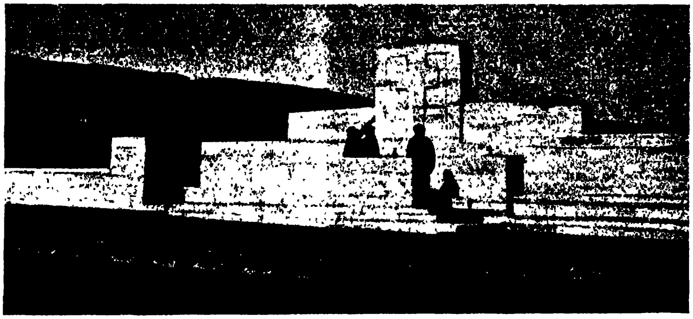

FIG. 4.—V. Beach Cemetery, Gallipoli.

In the advanced cemeteries on the Macedonian front, where the dead lie still guarding the line far from human habitations, Sir Robert Lorimer has replaced the Cross by a Cairn, conical in form, built of rough blocks on a concrete foundation; it is 11 feet 4½ inches in height, and is surmounted by a rough stone cross 10 inches square and 3 feet 10 inches in height. Here, also, he has designed a very striking monument for an Indian cemetery.

On the Gallipoli Peninsula we have had perhaps the hardest task of all. I was visiting the cemeteries there a fortnight ago, and have returned full of admiration for the artistic conception of our principal architect for that area, Sir John Burnet, and of gratitude to our staff for the way they have overcome difficulties which would have beaten all but the most stout-hearted. Here, too, the nature of the work has commanded a peculiar devotion to duty, which those engaged in it, comrades of those who fell there, regard as a matter of course. You will remember what a large part the sanctity of these graves played in the negotiations with the Turks at Lausanne; Australia and New Zealand, at any rate, to whom one third of the dead on the Peninsula belong, being prepared to secure that sanctity at all costs. There are 31 cemeteries, five in the Helles area, south of Achi Baba sixteen stretching in a chain from Suvla Bay to Anzac Beach. Some of them are on the beaches close to the blue Aegean Sea; others in the Anzac area, are in the sides of deep gullies, or on the ridge from which the Turk was never dislodged, close to his old front line. They are all now in Turkish Territory, from which the Greek population has been "exchanged," so that these in the Helles area are among a Mohammedan population, those to the North in practically uninhabited country. Neither the upright headstones nor the great Cross of Sacrifice, with its bronze sword were suitable for the conditions which will govern their maintenance in the future. The graves are marked by slabs on which are engraved the name, regimental particulars, date of death, a cross or other symbol of the dead man's faith, and an inscription chosen by the relatives. This slab, which is made in this country and sent out, is fixed and cemented into the top of a large concrete block about two feet of which is below the surface. The cemeteries had all to be built of local stone, the landing of heavy material presenting practically insuperable difficulties; fortunately stone existed of the best quality. The cemeteries are surrounded with great walls of massive rubble masonry, deep stone ditches running along their base. The outstanding feature of the design is a screen wall of ashlar masonry at the upper end of the cemetery, 20 feet to 30 feet in length, and 6 feet to 9 feet in height, according to the size of the cemetery. In the centre of this screen wall, in a curved recess with broad stone steps along its whole length, is a large plain cross in relief, cut into the massive stonework itself. In the larger cemeteries is placed the Stone of Remembrance, similar to that in France, but built up of large blocks cemented together. It was impossible to transport the seven-ton monolith over these roads and up the gullies. In some the screen wall is replaced by a massive pylon on which names of missing are inscribed. In Lone Pine Cemetery, on the summit of the Anzac ridge, is such a pylon, some 50 feet high, with the cross cut on all its four faces.

On this will be inscribed the names of 3,840 Australian and 1007 New Zealand soldiers who fell near by and have no known graves, and of 1,250 men from the two Dominions who died at sea. The view from this monument is one which can never be forgotten by those who have seen it, cemeteries in white stone from Suvla Bay in the distance marking the furthest points reached by our troops. In the Helles area the cemeteries are equally impressive, and what memories their names recall, Pink Farm, Twelve Tree Copse, Lancashire Landing, V. Beach, and, in the Suvla area, Green Hill, with its massive pylon, one of the largest cemeteries on the Peninsula.

It is absolutely impossible for me in one lecture to treat even briefly the cemeteries in the other countries, Palestine, with its largest cemetery on the Mount of Olives, the Cross of Sacrifice rising in the centre, Egypt, Mesopotamia, where Major Warren is our Principal Architect, and East Africa. But I cannot leave the subject without a reference to the commemoration of the missing, of those soldiers who have no known graves and those sailors who have no known graves but the sea. They can have no headstones on their graves, but the Governments of the Empire have decided that they shall not be without their record in stone. It was suggested by some that headstones should be erected to them in the cemeteries, but there was an overwhelming feeling against the false impression as to the existence of a grave which these would ultimately suggest. The participating Governments represented on the Imperial War Graves Commission have not all adopted the same method of commemorating these men. New Zealand, with smaller compact forces remaining together during the war, has records which enable her to commemmorate them in the cemetery near which they each fell. South Africa and Newfoundland are commemorating theirs on national memorials in France. The United Kingdom, Canada, Australia and India are, generally speaking, following a common system, which I will shortly illustrate.

All ships passing in the future in or out of the Dardanelles will sight on the highest ground above Cape Helles a monument rising 100 feet against the sky. On this will be inscribed the names of all the ships and military units which took part in the Gallipoli campaign; on walls around the base are carved the names of 12,000 men of Great Britain and Ireland who fell on the Peninsula, and of 200 Australians who were killed on the Helles area (the rest are commemorated on the Lone Pine Memorial), all of whom have no known graves. The site has been so selected that this monument to our missing dead will be for all time a mark for ships sailing these seas. It is the same height as was the Colossus of Rhodes. It will be completed in the early Autumn. At Port Tewfik, at the Southern entrance to the Suez Canal, is being built the monument to the Indian troops, the religion of many of whom has dictated a different form of burial to that represented by our graves. Sir John Burnet's design is a square obelisk 65 feet in height set on a large stone platform with flanking walls for the inscriptions, terminating with groups of sculpture by Mr. Jagger, each depicting a crouching tiger on guard defending the monument, the one from approach from the canal the other from approach from the sea. In Macedonia the Memorial to the Missing of the Salonika Force has for some time been finished. It forms part of the Memorial to this Force, the cost of which was borne by a fund subscribed by the troops themselves. The whole has been designed by Sir Robert Lorimer and built by the Commission. It is situated on Colonial Hill, overlooking Lake Doiran, near one of our largest cemeteries. You will see from the photograph that a short distance away from the four corners of the monument, which is 40 feet high, are four piers. Into the sides of these are sunk marble panels, on which the names of the missing are inscribed. In France similar Memorials will be erected, the sites have already been selected, and that at the Menin Gate, Ypres, is now building. On this will be inscribed in stone the names of 60,000 missing Englishmen, Scots, Welsh, Irish, Australian, Canadians, and Indians and Colonials, who fell in the Ypres Salient, but have no known graves. The memorial designed by Sir Reginald Blomfield occupies a position at the town end of the Causeway, across the moat leading to the Menin Road, over which passed, never to return, those who will be commemorated there. It is in the form of an arch or gateway, the main hall is about 70 feet span by 50 feet in height, and 130 feet in length from end to end. Looking at the arch from outside the old ramparts of which it forms a part, the main structure rises in three great steps, and is surmounted in the centre by the figure of a lion in repose; beneath the lion above the soffit of the arch is this inscription :—

> "To the Armies of the British Empire who stood here from 1914-1918, and to those of their dead who have no known graves."

In the same position at the other end of the arch is this inscription :—

> "Here are recorded names of officers and men who fell in Ypres Salient, but to whom the fortune of war denied the known and honoured burial given to their comrades in death."

I come last to the memorial that has been most recently completed, that at Chatham, to the dead of the senior service, which will be unveiled by the Prince of Wales on April 26th. The Admiralty appointed a Naval Memorials Committee in 1920, to advise us as to the most suitable form of memorials to the 25,567 ranks and ratings who had lost their lives at sea. The Committee decided on three memorials at the three manning ports, Chatham, Portsmouth and Plymouth. They came to the conclusion that, "It would greatly add to the sentiment and perpetuation of the memorial to associate it with some practical naval purpose. And what could one have to better fulfil both these conditions than a sea-mark or leading-mark near the foreshore ? Surely the combination of a Naval Memorial at Portsmouth, with a beacon to guide the ships into their Home Port, and to guide the liberty boats over the Swashway, will appeal to all."

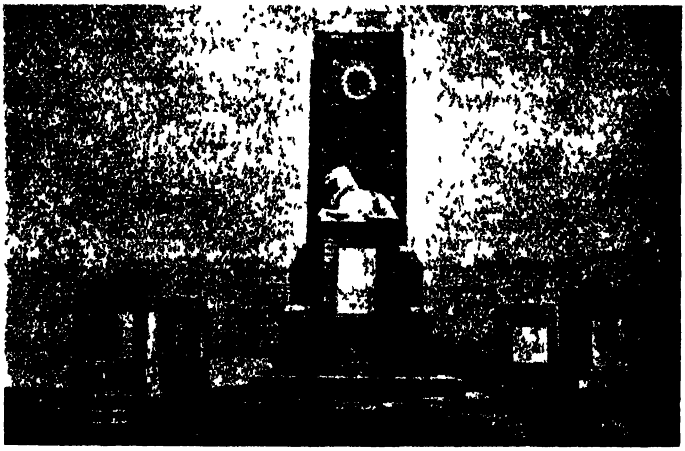

Fig. 5.—Lake Doiran Memorial, Macedonia.

The sites selected were in the Park on the North side of the Hoe at Plymouth, on Southsea Common at Portsmouth, and on the Great Lines at Chatham. The three memorials are similar in design. I will, therefore, show you a sketch of Chatham. The names of the dead are recorded on bronze panels that in front bearing the following inscription :—

> "In honour of the Navy and to the abiding memory of these ranks and ratings of this Port who laid down their lives in the defence of the Empire and have no other grave than the sea. 1914-1918."

That on the back gives the single ship actions, and those on the sides general actions at sea and actions with enemy land forces. The total height of the Memorial is about 100 feet. In describing his design, Sir Robert Lorimer says:—

> "The crowning feature of the four buttresses which project at the four angles of the base will be a seated figure of a lion.
>
> "The column which rises from this base is treated with extreme simplicity until the top is reached, where at the angles there are bronze figures representing the four winds and projecting from the angles below these figures are to be carved the prows of ships, the crowning feature of the memorial being a golden globe. The figures and globe are intended to symbolise our far-flung Empire." The sculptor is Mr. H. Poole.

Two other Memorials which may be classed with these, I should like to show you; that to the Native East African Troops, designed by Mr. F. A. Stevenson, and the plaques designed by Lt.-Col. H. Carl de Lafontaine being erected in certain Cathedrals in France and Belguim.

I cannot close this very brief sketch of the work of the Imperial War Graves Commission without reminding you that in accordance with the resolution of the Imperial War Conference, 1918, the cost is borne by the respective Governments in proportion to the number of the graves of their dead. The Commission is the first truly Imperial organisation in the sense that it is equally responsible to each of the participating Governments, all of whom through their representatives take an active part in the control of the administration. The work that falls on the Commissioners themselves is by no means light; the full Commission has met once a month during the last six years, and the Finance Committee once a fortnight. That is as it should be, because if these war cemeteries and monuments to the dead are to be in every way worthy of those whom they commemorate, there must be no lavish expenditure. There is every reason to think that when we have completed our work we shall have exceeded neither the estimate of time, nor of money, which was approved by the Imperial Conference, that is, an average expenditure of £10 a grave and ten years. We have not built up an organisation to do the work of construction itself, but have chosen what is on the whole the more economical way of letting out the contracts, when the drawings and designs are prepared, to public tender, and we have every reason to be grateful to the contractors for the way they have done their work.

Before I close, may I ask you once more to follow in your imagination this chain of cemeteries round the world? From France, through Italy, Macedonia, Gallipoli, Syria, to the Mount of Olives; then on to Egypt, Mesopotamia, East Africa, and round again to Great Britain. These cemeteries and memorials have been built in honour of our dead; they are at the same time monuments unique in history to the achievements of the British race and the British Commonwealth of Nations, they are in all parts of the old world, and in that which was unknown to ancient empires and conquerors, and bear a message to future generations as long as the stone of which they are constructed endures. If we ask ourselves what that message will be, I think our pride in the memory of those whom we honour will be lighted up with an unshaken hope in the ultimate triumph of the faith and ideals in which they died, a hope that they may lie for ever there, this silent League of British Nations, their sleep unbroken by the call to arms or the din of war, guarding as they won the peace of the civilised world

DISCUSSION.

Dr. A. W. Hill, F.R.S., Director of the Royal Botanic Gardens, Kew, remarked that last summer he made a tour round a good many of the cemeteries in France, and he had been most favourably impressed with their remarkably fine condition, both in regard to those which were finished, and those which were still waiting their final completion with the headstones. It was very possible that anyone seeing the cemeteries out in the wilds which were not fitted with their headstones and which had not received any particular architectural treatment, but only gardening attention, might think that in some ways perhaps they were more beautiful because one saw such a wealth of flowers and such an expanse of grass. He was not saying for one moment that the finished work was not essential and most necessary, but one could see, he thought, rather better in the unfinished cemeteries the beauty of the gardening effects. It was extraordinary what the British gardeners had done in France and Belgium, both in the sandy wastes and in swampy sites. The British gardeners had made there lawns which would be the envy of many people at home. It was a perfect triumph for the British gardener, and it was entirely due to the horticultural officers and the gardening staff who were working in those parts. The same remarks applied equally to Italy. With regard to the point which Sir Fabian had raised as to the desire of the colonies to put in plants representative of the different parts of the Empire from which the fallen had come, that had been a matter of considerable difficulty. When he had been approached on the matter he had done his best to think of suitable plants. The temperate parts of the world had afforded very little difficulty. From Canada, for instance, no difficulty had been experienced with regard to maples which would be hardy in France. They had not relied on maple seed, as they could have done, which had been ripened in this country, but they had written out to the botanical authorities in Canada for seed, and maples from seed ripened in Canada had been raised in France and at Kew. In the same way the South Africans had been anxious to have some representative plant, but there was nothing which could be grown in those cemeteries in France which was typical of South Africa, except annuals. The Red-hot poker (Kniphofia) was about the only good hardy perennial South African plant, but was not very suitable for a cemetery. Some years ago, however, there had been sent out from Kew to South Africa acorns, from which, in South Africa, they had reared large quantities of oak trees. Therefore, it had seemed rather fitting that South Africa should send over acorns from these trees which had originally gone out from England. That had been done, and young oak trees were now being raised in France from those South African acorns. For the Australian cemeteries there happened to be a hardy form of Eucalyptus which it was believed would grow in France, for seed of which we were indebted to Miss Balfour, of Whittingehame; while for the cemeteries where New Zealand soldiers were buried the Daisy Bush (Olearia) and New Zealand Veronicas were being used. An endeavour was being made wherever there were overseas soldiers buried to plant some tree or shrub which was characteristic of the place from which they came.

Sir Frederic G. Kenyon, K.C.B., said he would like to add his testimony to the general effect which the cemeteries produced on the visitor who saw them. He had seen a great number of the cemeteries in France and Belgium, and one could only come away with a sense of great satisfaction and great thankfulness at the success of the work of the Commission. One got in the first instance a sense of order and discipline in those rows of headstones. They suggested almost a battalion on parade; at any rate they carried out the soldierly idea of order and of discipline, and the principle of equality of treatment for all ranks. The cross also impressed the lesson of sacrifice, the sacrifice made by those men for their country. At the same time they were not depressing places; they were made bright by the flowers and the grass, and in that connexion he would like to add his testimony to the admirable work of the horticultural staff—not only their actual work, but the spirit in which they carried out their duties. He had heard no word of complaint anywhere. He had found the men everywhere proud of their work, and only too glad to help visitors to find the graves of which they were in search. The Commission had every right to be proud of their work, and he believed the country and the Empire would always be grateful to them.

The Chairman (Lord Askwith) doubted whether the subject was one for discussion; he would prefer to ask the audience to thank, with acclamation, Sir Fabian Ware for the account which he had given of the architectural and artistic features of the graves. It had required some influence on his own part upon an old friend to cause him, in the midst of his other heavy work and when he was engaged in planning journeys and in arranging the continuous work of his office, to sit down and compose a discourse; but he had put it to Sir Fabian that it was of great importance to let the world know now, through the Society's Journal and through the press, what was being done with regard to the Empire graves. He knew that none could do that with the same delicacy and literary skill as Sir Fabian Ware could command. Sir Fabian had acceded to his request, and the result had been seen that night. He did not think those present would regret having attended. The address must have caused many thoughts to surge through the minds of most of them. He did not wish to examine them too closely, but there were one or two thoughts which must perhaps have occurred to the minds of most people, which had not occurred to them before the lecture. One that had struck him very much had been that all creeds, all colours, all kinds and types of men were being honoured and their names handed down in those memorials. Not only were the monuments put up in France, but they were put up in every country and every continent in the world. They knew not what the fate of those memorials might be 2,000 years hence, when other races, other peoples and other beliefs might hold the world, but at least there would remain in many parts of the world those great monuments, graven with the names of men and graven in languages of different kinds. It was well, he thought, that at the present time the history of the matter should be brought before the country and put upon permanent record, and nobody could have done that better than Sir Fabian. In the name of the audience he thanked him very much for his lecture.

Sir Fabian Ware, in acknowledging the vote, said the subject was an extremely difficult one to talk about, or even to read about; and if it had not been for the atmosphere which there had been while he was speaking, it would have been impossible for him to have got through the lecture. He desired to thank the audience for their very kind sympathy and help.

The Meeting then terminated.

NOTES ON BOOKS.

INTERNATIONAL ORTHOTYPE. By A. Deane Butcher, London: F. J. Dangerfield. 1s. net.

There are about sixteen vowel sounds in the English language, and as there are only five vowels, each vowel or diphthong must do duty for several sounds. The difficulties to a child learning to spell, or perhaps even more to a foreign student learning to pronounce English, are too well known to be insisted upon here. The combination of letters "ough," for instance, may be pronounced in five or six different ways. How is the child or the foreign student to know which is the right one?

A great many systems have been devised to deal with this problem. The method known as "Simplified Spelling" has a good deal to be said for it, but many people find it hard to reconcile themselves to the printed result; while the drawback of most of the phonetic systems is that the student is apt to be bewildered by the multiplicity of unfamiliar symbols. In "Orthotype" Miss Deane Butcher uses the ordinary vowels, and in addition to these ten simple signs placed over them. The ordinary spelling of the words is thus retained, while the symbols indicate the correct pronunciation. A child who has grasped the meaning of these symbols should have little difficulty in pronouncing correctly a passage of French printed in "Orthotype."

It would not be possible or desirable to pronounce an *ex cathedra* opinion as to value of this system until one had had practical experience of it in teaching young pupils or foreigners, but on the face of it, "Orthotype" appears to be a simple and sane attempt to deal with a difficult problem, and it is to be hoped that educationists will be found willing to give it a fair trial.

COMMERCIAL TEXT-BOOKS.

In connexion with the Society's examinations frequent enquiries are made by teachers and candidates as to suitable text-books on Business Training, Languages, etc. It is, however, a well-established rule of the Society not to recommend any special works in the various subjects comprised in its scheme of commercial examinations, and many candidates are consequently disappointed in their endeavour to obtain advice and guidance in the choice of text-books.

It is true that most publishers possess a reference library for the use of teachers, but this did not meet the want of candidates who hitherto called at the Society's House for such information. It was thought, therefore, that if the leading publishers of commercial text-books would consent to place at the Society's disposal a selected collection of works of this nature, it would be a valuable guide to teachers and students who are searching for suitable text-books.

The leading educational publishers were therefore approached and the response has been so satisfactory that a very complete collection of books has now been assembled and placed in a special section of the Library. Teachers and candidates are cordially invited to consult these books; they will find a wide range of choice of books on every subject of examination and by comparing one work with another can readily ascertain which will aid them best in their studies. This Library is for reference purposes only, and when the appropriate book is found the student is expected to obtain it from the publisher in the ordinary way. Selected books have been supplied by the following publishing houses:—

Messrs. G. Bell & Sons, Ltd.; Blackie & Son, Ltd.; Butterworth & Co.; Cambridge University Press; Arthur Fieldhouse; Gregg Publishing Co.; Librairie Hachette; George G. Harrap and Co., Ltd.; Hirschfield Brothers, Ltd.; Hodder & Stoughton, Ltd.; Jordan and Sons, Ltd.; Longmans, Green & Co.; Macdonald & Evans; Macmillan & Co., Ltd.; A. Munro & Co.; John Murray; Oxford University Press; George Philip & Son, Ltd.; Sir Isaac Pitman & Sons, Ltd.; University of London Press, Ltd.; University Tutorial Press, Ltd.; Effingham Wilson.

PATCHOULI LEAVES AND OIL TRADE OF SINGAPORE.

The export of patchouli leaves and oil is an item of some importance in the Singapore district. From a report by the United States Vice-Consul at Singapore, it appears that of the leaves exported, 90 per cent. are grown in the interior of the northern portion of the island of Sumatra, and are shipped to Singapore for export. The remaining 10 per cent. are grown on the island of Singapore and in the Malay State of Johore. The leaves, which are collected by the natives, are sent down the rivers to small ports on the north-western coast of Sumatra. At these points they are pressed into bales of 280 pounds each and are shipped to Singapore in gunny sacks.

The imports of patchouli leaves into Singapore for the year 1922 amounted to 10,853 piculs (1 picul =133⅓ pounds). Upon arrival the baled leaves are sold to exporters. The exports from Singapore for the year 1922 amounted to 6,837 piculs. A total of 4,016 piculs (the difference between the amount of leaves imported and exported) was used for oil production.

The average production of patchouli oil is from 2,000 to 3,000 pounds a month. Most of the leaves exported were destined for the United States, with India and Europe the next best customers.

Patchouli oil is shipped in 20-pound iron drums, packed in sawdust, two to a case. At the present time there are three oil distillers in Singapore, all of whom are Chinese firms whose distilleries are equipped with fairly up-to-date machinery.

SHIPBUILDING ON THE CLYDE IN 1923.

The *Glasgow Chamber of Commerce Journal* quotes some figures relating to shipbuilding on the Clyde last year. There were launched only 122 vessels measuring 175,528 tons, and the marine propelling engines constructed in the district made an aggregate of only 166,956 I.H.P. These figures, compared with 145 vessels of 388,481 tons and 349,329 I.H.P. in 1922—which was itself a very poor year—so that there was a decrease in the twelve months of 21 vessels, 212,953 tons, and 182,373 I.H.P. Less than half the tonnage of 1922 was launched, and much less than half the work was actually done. Most of the tonnage was launched early in the year, and so represented work done in 1922, while the launching tonnage fell off during the summer and autumn until remarkably low figures were reached. This was explained mainly by the lock-out of iron-workers, but to some extent also by the lack of demand for new vessels. How poor the year really was may be understood best, however, when the output of normal years is recalled. The average of the decade before the war was about half a million tons per annum, and the highest point reached was in 1913, when 370 vessels of 756,976 tons were launched on the river, and machinery of 1,111,440 I.H.P. was manufactured. Not since 1886, when what was even then considered the very poor total of 166 vessels of 172,440 tons was launched, was the output of the Clyde so low as in 1923. Last year the river went back for more than a generation, and reached a level which represented less than one-third of the ships of its best year, less than one-fourth of the tonnage, and not much more than one-seventh of the horse-power.

It is, however, satisfactory to learn that shipbuilding prospects improved considerably near the end of the year, and are now better than they were all through 1921, 1922, and the first eleven months of 1923. There is a very general belief that the worst of the depression in shipping is past, and that there will soon be more profitable employment for general, cargo-carrying tonnage. There are now comparatively few vessels laid up, and owners are inquiring frequently for prices of new ships. A considerable number of orders have been placed, but these are almost wholly for vessels of special types—railway steamers, for example, and harbour service craft—and for motor-ships. There are now under construction on the Clyde 119 vessels of 528,914 tons. Of these, 74 vessels of 326,564 tons are at or above Dumbarton and at the Ayrshire ports; and 45 vessels of 202,350 tons in Greenock and Port-Glasgow. The total compares with 96 vessels of 468,754 tons three months ago, and 83 vessels of 504,724 tons a year ago, so that there has been a fairly definite recovery in the trade. It is difficult to say how much of the work on hand represents vessels delayed by the ship-yard lock-out, but it seems clear that there would have been more work if there had been no dispute. The total under construction is still low—much lower than the average of the twenty years previous to 1923—and it is far short of the 267 vessels of 1,345,864 on hand in March, 1921. It is, however, enough to be going on with if trade conditions are such that orders are received within the next few months to an extent greater than the vessels completed. If this is the case, shipbuilding and marine engineering, and all other West of Scotland trades, will have a much better year than they had in 1923.

The relatively greater decrease in engineering than in shipbuilding is explained by the stoppage of warship construction. Not one naval vessel was launched on the river, and not one set of naval propelling engines. In every pre-war year within recent times there were a considerable number of high-powered naval vessels, while in several of the war years there were so many that the horsepower of the district was enormously higher than that of 1913. These were abnormal years, and cannot be taken into account when trade fluctuations are being considered. The engine-shop work of 1923 was all for mercantile vessels of comparatively low power, but some of it was of exceptional interest. Only three installations of geared-turbine machinery were constructed, but eight sea-going motor ships were supplied with engines, and arrangements were made for the construction at Glasgow of large Diesel engines of the new double-acting type. One set of this type—the first made in Great Britain or Ireland—has been completed at Whiteinch to a design which is new, and is wholly Clyde in conception and workmanship, while others of the Copenhagen design are being constructed at Glasgow. Poor, therefore, though the output of the year was, it represented technical progress of a very definite kind.

HYDRO-ELECTRIC DEVELOPMENT IN NEW ZEALAND.

With reference to the note on potential water power in New Zealand published in the *Journal* of 11th January, some interesting details regarding the development of hydro-electric power in the Dominion during the financial year ended 31st March last are given in the Report on the Economic and Commercial conditions in New Zealand by H.M. Trade Commissioner.

The total expenditure during the financial year was £450,247. The Lake Coleridge power house has been brought up to the full capacity of the existing tunnel by the installation of two additional generators of 3,000 kw. each, making the total power installed 12,000 kw. The load has grown rapidly, and has already reached 10,500 kw., and it has, therefore, been decided to proceed at once with further extensions which will necessitate a second tunnel and intake works. The proposed extensions will consist of two units each of 7,500 kw. with provision for a third unit to be added when necessary. Transmission lines have been completed to Ashburton and Timaru.

The Hora Hora power-house has been in operation throughout the year, the existing plant 6,300 kw. is overloaded and demand is increasing in the

Waikato. The Auckland Electric Power Board is also negotiating for a supply from Hora Hora in advance of the supply from Arapuni, which will not be available before 1928. An extension of two units each of 2,000 kw. has been put in hand, and the transmission line to Auckland is under construction.

No work has yet been done in the main plant at Waikaremoana, but as a small supply was urgently wanted at Wairoa the two exciter sets were installed and have been giving service since December, 1922. No statement has yet been made as to when work on the main plant will be commenced.

The Mangahao plant is making substantial progress, the tunnels and headworks are well in hand, the power-house is under construction, and installation of the machinery was hoped to be begun in November. The Minister of Public Works has stated that he hopes to have the plant ready to operate about next June. Transmission lines to Wellington, Marton, Dannevirke, and Masterton are under construction, and surveys are being made for lines to Napier and Wanganui.

It is proposed to proceed at once with the installation of three units of 15,000 kw. each at Arapuni.

Dunedin City is extending the Waipori Falls station by the addition of a 3,000-kw. unit, and is making provision for the ultimate installation of three more such units. The Southland Power Board is pushing on the Monowai scheme of two 2,000 kw. units, with provision for extension by four additional units. The New Plymouth Borough has plans in hand for a station of 4,500 kw. on the Waiwakaiho River, and the Taranaki Power Board proposes to construct a small station of 1,500 kw. at Tariki.

Several smaller power stations are in hand, and preliminary investigations have been made of sources of power for Otago, Marlborough, Nelson and Westland.

Altogether the Public Works Department are planning to spend well over a million pounds per year on hydro-electric power development and transmission during the next six or eight years.

SOUTH AFRICAN DRIED FRUIT AND PINEAPPLE INDUSTRIES.

In the course of his Report on the Economic Conditions in South Africa, H.M. Senior Trade Commissioner in the Union states that the dried fruit industry is slowly establishing itself on a sound basis. There is a growing tendency on the part of farmers to recognise the need for supporting central grading and packing establishments, and with these in full operation there is a very sound outlook for the industry. With all the necessary fruits growing to perfection it is only a matter of applying correct up-to-date methods to enter the world's markets with every assurance of success.

The western districts of the Cape Province are, by means of their climatic conditions, generally looked upon as being the home of soft fruits and hence the centre of the industry. Thus favoured and having easy access to the best shipping facilities offered in the country they are in a very strong position. The development of the irrigated areas of the Eastern Province will result, however, in the entry of rivals of no mean order for—given water—there are large blocks of land in that area which will produce excellent fruit. It is most probable that big developments in producing fruit for drying will take place in the near future.

As regards pineapples, it appears that despite the large production the position of this fruit is disappointing, and unless the present efforts to grapple with the question of disposal meet with success, large areas under cultivation will prove a failure. The pineapple of the country, though small, is of excellent flavour and readily wins appreciation when known. If sound arrival oversea could be ensured, the quality of the fruit would soon establish a market. The main handicap to development has been the irregular condition in which so many consignments have opened up.

Taking the fruit industry generally, while it is recognised that it is a luxury trade, there is no question that its outlook is sound, and all that is needed is continual pressure in every direction which will tend to better the condition on arrival and the selling life of the fruit in European markets, and the full exploitation of those markets by advertising and thorough distribution.

GENERAL NOTES.

Fourth International Conference on Soil Science.—The Fourth International Conference on Soil Science will be held in Rome, from May 12th to 19th. The first was held in 1909 in Budapest, the second in 1911 in Stockholm, and the third in 1922 in Prague. The Italian Minister of National Economy, Prof. Corbino, has promised to be the honorary chairman. The Conference will be held at the International Institute of Agriculture in Rome.

Mining Operations in the Rand.—Some remarkable figures are quoted by the *African World* regarding the magnitude of the excavated work done by the mining industry of the Rand, which is equal to a distance ranging from the Cape of Good Hope to the Equator. The approximate mileage of underground excavation, that is to say, main shaft sinking, main drives, cross-cuts, and other development achieved on the Witwatersrand since production commenced in 1887 up to date, has been 4,000 miles, which would suffice to drive a tunnel from Cape Town to Stanleyville, the equatorial capital of the Belgian Congo, according to an official calculation, which has been circulated by the Industrial News Service. Up to the end of last year, the total mileage of developments on the Rand has been approximately 2,893 miles, and as the mines are carrying about 70,000 ft. of development per month, or, say, 13¼ miles per month, this means that the total development to date has just been about 3,000 miles. This figure and the comparisons as to distance expressed above will enable one in some measure to realise the vast amount of developing operations that have been carried out, and the figures quoted, it may be remarked, are only for development, and do not take into account excavations which have to be made in respect of stoping or mining the actual ore.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings at 8 o'clock.

APRIL 30.—BRIGADIER-GENERAL SIR HENRY MAYBURY, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "The London Dock District and its Roads." HARRY GOSLING, C.H., M.P., Minister of Transport, will preside.

MAY 5 (Monday).—T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MAY 7.—J. ROBINSON, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation." ADMIRAL OF THE FLEET SIR HENRY JACKSON, G.C.B., K.C.V.O., F.R.S., will preside.

MAY 14.—

MAY 21.—(Trueman Wood Lecture.) SIR WILLIAM J. POPE, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, "Tho Outlook in Chemistry."

MAY 28.—MRS. ARTHUR MCGARTH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

Friday afternoons, at 4.30 o'clock:—

MAY 2.—JOCELYN F. THORPE, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India."

Date to be hereafter announced:—

BHUPENDRA NATH BASU, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

DOMINIONS AND COLONIES SECTION.

TUESDAY, MAY 27, at 4.30 o'clock.—C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

WEDNESDAY, JUNE 4, at 4.30 o'clock.—THE RT. HON. SIR FREDERICK LUGARD, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates."

MONDAY, JUNE 16, at 4.30 o'clock.—C. V. CORLESS, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada."

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, APRIL 14 .. British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. D. F. Slathowwer, "Modern Dutch Architecture."

Geographical Society, Lowther Lodge, Kensington Gore, S.W., 5 p.m. Mr. D. Brunt, "Climatic Continentality and Oceanity."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal Meeting.) Mr. J. R. Bedford, "Some Idiosyncrasies of Electrical Manufacturers."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 7 p.m. (Graduate Section.) Mr. A. H. Fuller, "Mechanical Refrigeration for the Small User."

At the Chamber of Commerce, New Street, Birmingham, 6.45 p.m. Dr. L. Aitchison, "Light Alloys for Pistons and Connecting Rods."

East India Association, at the Carpenters' Hall, Throgmorton Avenue, E.C., 3.30 p.m. Mr. A. L. Howard, "The Forests and Timbers of Burma."

Brewing, Institute of, at the Engineers' Club, 39, Coventry Street, W.C., 7.30 p.m. Mr. W. A. Riley, "Steam and Super-Heated Steam."

TUESDAY, APRIL 15 .. Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m.

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m.

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Mr. R. N. Salaman, "An Analysis of Jewish Types."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Lieut.-Commander R. E. Rendall, "One Exposure Tri-Colour Cameras."

Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 5.30 p.m. Mr. A. J. Brickwell, "The Rating of Railways and Docks."

Mechanical Engineers, Institution of, Railway Hotel, Coventry, 7 p.m. Dr. L. Aitchison, "Light Alloys for Pistons and Connecting Rods."

Zoological Society, Regent's Park, N.W., 5.30 p.m. (1) The Secretary, "Report on the Additions made to the Society's Menagerie during the month of March, 1924." (2) Mr. Guy C. Robson, "On the Cephalopoda obtained in South African Waters by Dr. J. D. F. Gilchrist, in 1920-1921." (3) Mr. Basanta Kumar Das, "On the Intra-Renal Course of the so-called 'Renal-Portal' Veins in some Common Indian Birds."

WEDNESDAY, APRIL 16 .. Transport, Institute of, Manchester. Mr. A. J. Lyddon, "Road Construction."

Mechanical Engineers, Institution of, Star and Garter Hotel, Wolverhampton, 7.30 p.m. Dr. L. Aitchison, "Light Alloys for Pistons and Connecting Rods."

THURSDAY, APRIL 18 .. China Society, at the School of Oriental Studies, Finsbury Circus, E.C., 5 p.m. Rev. E. Morgan, "An Ancient Philosopher's View of the Perfect Life."

Journal of the Royal Society of Arts.

No. 3,726. VOL. LXXII.

FRIDAY, APRIL 18, 1924.

All communications for the Society should be addressed to the Secretary, John Street, [illegible] W.C. (2)

26 MAY 1924 PUB

NOTICES.

TRUEMAN WOOD LECTURE.

In consequence of illness, PROFESSOR C. VERNON BOYS, F.R.S., will be unable to deliver the Trueman Wood Lecture on "Calorimetry," which he had arranged to give on WEDNESDAY, MAY 21st. His place will be taken by SIR WILLIAM J. POPE, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, who has chosen as his subject "The Outlook in Chemistry."

EIGHTEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 9th, 1924; SIR FRANK DYSON, LL.D., F.R.S., Astronomer Royal, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Fabini, H. V., Richmond, Surrey.
Gothard, H. A. S., Bickley, Kent.
Martynik, Jan, Gemsa, Egypt.
Sandell, H. W., North Shields.

The following candidates were duly elected Fellows of the Society:—

Eedy, Arthur Malcolm, Sydney, Australia.
Muir, James, London.
Rothfeld, Otto, I.C.S., London.

A paper on "The Free Pendulum" was read by MR. FRANK HOPE-JONES, M.I.E.E., Vice-Chairman, British Horological Institute.

The paper and discussion will be published in a subsequent number of the *Journal.*

VISIT TO THE GUILDHALL.

On behalf of the Fellows of the Society and their ladies, the Council have gratefully accepted an invitation from Mr. H. G. Downer, LL.B., a member of the Common Council, to inspect the Guildhall, including the Art Gallery of the Corporation of London, on Thursday, May 8th, at 2.30 p.m.

Sir Alfred George Temple, F.S.A., will act as escort in the Art Gallery, and Mr. Deputy Alderton, C.C., in the Council Chamber, Crypt and other places of interest in the Guildhall.

Fellows desirous of availing themselves of the invitation should inform the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2, on or before May 3rd, mentioning the number of their party. No tickets are necessary.

Those attending are requested to assemble at the main entrance to the Guildhall in King Street, Cheapside, at 2.30 p.m.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 19TH, 1924.

LORD CLINTON (Forestry Commissioner) in the Chair.

THE CHAIRMAN, in introducing the author, said Mr. Robinson was a member of the Forestry Commission, and, in addition, was the advisor to that Commission upon all technical matters. Much of the information contained in the paper was the result of Mr. Robinson's personal observation whilst in Canada last Autumn representing the Forestry Commission at the Imperial Forestry Conference. That was a Conference which was of very great importance. It took place periodically and gathered together a great deal of useful information, not the least of which was as to what were the actual resources of timber, not only of the Empire, but of the whole globe. A telegram had been received from Sir William Schlich, whose name was very well known among all foresters as the pioneer of forestry in this country, to the following effect: "Sorry heavy cold cannot come. Congratulate Robinson on complete paper. Could not have added anything but praise." He (the Chairman) could assure the audience that that might be regarded as very high praise indeed.

The following paper was read:—

THE FORESTS AND TIMBER SUPPLY OF NORTH AMERICA.

By R. L. Robinson,
Forestry Commissioner.

The information which I have the pleasure of placing before the Society has been compiled from a number of sources. The British Empire Forestry Conference which was held in Canada last summer afforded unrivalled opportunities for investigating the forest position in Canada. When it was ended, Lord Lovat, the Chairman of the Forestry Commission, Mr. Fraser Story and I visited different parts of the United States forest regions, while Dr. Borthwick inspected the Queen Charlotte Islands. The chief parts of the Continent for which we have no first-hand information are Alaska and Mexico. Our visit to the United States synchronised with considerable activity in the forestry world. A Committee of the Senate was engaged in investigating the whole position, and we had unusual opportunities of obtaining data from that source and through the Officers whom Colonel Greeley, Head of the United States Forest Service, placed at our disposal. The most important of recent literature on the subject of my paper, exclusive of statements presented to the Empire Forestry Conference, is a book entitled "The Forest Resources of the World," by Zon and Sparhawk.

IMPORTANCE OF NORTH AMERICAN FORESTS.

It will clear the way if I state at once that the timber supply question in North America centres mainly around what is happening in the United States. That great country steadily increased its population from under 40 million in 1870 to over 105 million in 1920, while its industrial development during the 20th century has far outstripped that of any other nation. The forests have played an extremely important part in this development. Passing from the early colonial days, when timber was the chief commodity of exchange against the manufactured products of Europe, the abundance of cheap supplies of timber rendered possible the rapid construction of houses (over 90% of the houses of North America are made of wood), and the construction of a vast system of railways. Timber, in fact, took the place, to a large extent, of the more durable materials used in Europe. More recently wood, when manufactured into paper, has played its part in advancing American civilisation: the consumption of paper in the United States is approximately 150 lbs. per capita or 8 million tons, of which 90% comes out of the forests.

MAIN FEATURES OF NORTH AMERICA.

For convenience I am taking North America to mean the whole Continent and Islands as far south as, and including Mexico, but excluding the West Indies. The range in latitude is from well within the tropics to well within the Arctic Circle. The total land area is approximately 5,188 million acres, of which 1,903 million acres comprise the United States, 2,387 million acres Canada and 493 million acres Mexico. The most striking topographical feature of the Continent is the great mountain system, which can be described collectively as the Rocky Mountains, running close to and roughly in the same general direction as the Western Coast line, with but few breaks from Alaska through British Columbia, the States of Washington, Oregon, California, Idaho, Montana, Wyoming, Utah, New Mexico and Arizona, and Mexico to Central America. The system comprises numerous mountain ranges and plateaux which have important reactions on climate and hence on timber growth. East of the mountains lies the great central plain which runs without any very notable interruptions, save the Canadian Lakes, from the mouth of the Mississippi to the Arctic Ocean. East again of the Central Plain the Appalachian system of mountains runs north-east from the States of Georgia and Alabama to Pennsylvania, and continues with interruptions into Maine. The broad strip between this system and the Atlantic calls for no special comment.

The North and North-East of the Continent is hilly country which has been severely ground down by ice action, a land of innumerable lakes, streams and waterfalls.

FOREST REGIONS.

Over such a large range of conditions the number of tree species is naturally great, greater in fact than one would expect by comparison with Europe. The number of commercial species of trees in the United States alone is upwards of one hundred, and these combine to form very many more forest types and sub-types. It is impossible within the limits of my remarks to describe types, and I must therefore confine my descriptive remarks to a brief survey of the main forest regions, a procedure which, though quite unsatisfactory from a forestry point of view, has distinct advantages as regards timber supply and utilisation.

1. THE NORTHERN CONIFEROUS FOREST stretches in a great belt, 300-400 miles wide, from Labrador, north of the prairies, to Alaska. Newfoundland may conveniently be included in this region. The chief species are white spruce (*Picea Canadensis*) on the better soils, and black spruce (*Picea mariana*), in the swamps; locally, balsam (*Abies balsamea*) tamarack (*Larixl aricina*) jack pine (*P. Banksiana*) white pine (*P. Strobus*) and red pine (*P. resinosa*) occur. The area has been extensively burned, and in the brulées birch and aspen take the place of conifers, excepting jack pine. As the Arctic Circle is approached the growth becomes stunted, and timber of commercial size is confined to the watercourses.

2. THE GREAT LAKES—ST. LAWRENCE region marks the best development of the white pine, which is associated with red pine. It has been the scene of extensive lumbering in Canada since the earliest times The original character of these forests has been greatly altered by logging and fire; hardwoods, spruce, jack pine and balsam have largely replaced the white pine.

3. THE NORTH-EASTERN FORESTS OF THE CANADIAN MARITIME PROVINCES AND NEW ENGLAND STATES. The most important species are the red spruce (*P. rubra*), white spruce and balsam fir, associated with jack pine, tamarack and black spruce. Considerable areas of hardwoods (maple, beech and birch), either pure or in mixture with white pine and hemlock (*Tsuga Canadensis*) also occur.

4. THE UNITED STATES CENTRAL AND SOUTHERN HARDWOODS formed originally a vast forest of extraordinary value. In the valley of the Mississippi and its tributaries, and in the Southern Appalachian Mountains, occur those species (oak, ash, hickory, walnut, yellow poplar) which have become standard hardwoods almost the world over, as well as many other species, such as chestnut, of great local utility. In the river bottoms of the Southern States occur red gum (*Liquidambar styraciflua*), *Nyssa* or cotton gum. The forests are not exclusively hardwoods, since species from the Northern forests, such as white pine, stretch down into the Appalachians, while cypress (*Taxodium distichum*) is an important species in the swamps. The pines also invade the hardwood areas on the South.

5. IN THE SOUTHERN PINE REGION, the forests consist chiefly of yellow pines, viz.: long leaf (*P. palustris*), loblolly (*P. taeda*), short leaf (*P. echinata*), and slash pine (*P. Caribaea*). The hardwoods of the central region also come into mixture with the pines, but are then relatively unimportant.

6. THE ROCKY MOUNTAINS REGION. The composition of the forests varies greatly with latitude and elevation. In the North, spruces (white and Englemann's) predominate, but are replaced on burned areas by lodge pole pine (*P. Murrayana*). From the south of British Columbia southwards other important trees such as yellow pine (*P. ponderosa*), Western larch (*L. occidentalis*), white fir (*Abies concolor*) come in. There are also in the wetter and lower belts forests resembling very closely the Pacific coast forests. The distribution of forest throughout the region is uneven, and towards the South the forest areas are greatly broken up by treeless stretches of plateau and arid country.

7. THE PACIFIC COAST FORESTS are probably the most interesting coniferous forests in the world, whether they are considered from the point of view of variety of species, rapidity of growth or dimensions of individual trees. They are particularly interesting to British foresters since two of the most important trees—Douglas fir (*Pseudotsuga Douglasii*) and Sitka spruce (*P. sitchensis*), grow with equal rapidity in this country.

In the North the commercial forests of Alaska consist of a very narrow strip of Sitka spruce with a small proportion of Western hemlock (*Tsuga heterophylla*). In the Queen Charlotte Islands Sitka spruce is still the principal tree, and there reaches its best development. Further south it gives pride of place, however, to Douglas fir and red cedar (*Thuja gigantea*), with which are associated locally other useful species such as hemlock and western white pine (*P. monticola*). The coastal belt runs south in a strip rarely more than 50 miles wide, but broadens out to about 150 miles in Washington. To the East of the Cascades, yellow pine comes in, and there are extensive stands of that species and western white pine. North of San Francisco lies the interesting and valuable redwood belt (*Sequoia sempervirens*), with stands of timber containing 50,000 cubic feet per acre and numerous individual trees upwards of 300 feet high and 15 feet in diameter.

The Sierra Nevadas are also heavily forested with yellow pine (*P. ponderosa*), sugar pine (*P. Lambertiana*), and several silver firs. Here also grow the "big trees" (*Sequoia gigantea*), of imposing dimensions.

8. THE MEXICAN FORESTS can be roughly divided into three main types. There are, first, the tropical forests running up from sea level to about 2,500 feet, consisting of very numerous species, of which mahogany, cedar (*Cedrela odorata*) and dyewood are common articles of commerce. This zone is succeeded by a transition forest containing oak, cherry and other hardwoods, with a sprinkling of pines at higher elevations. The most extensive and important forests are the coniferous forests of the mountains, which are predominantly pine, both white and yellow.

EXTENT OF FORESTS.

The total area of North America which is covered with forest or wood of some sort or another is of the order of 1,500 million acres, of which some 770 million acres are in Canada and Newfoundland; 550 million acres are in the United States; 70-150 million acres are in Alaska, and 74 million acres are in Mexico. It is impossible to be precise with these figures, since large areas which are believed to be mainly forest have scarcely been explored, much less mapped. It would appear from these figures that the area of forest in North America is about double that in Europe. From the point of view of timber supply, however, very great deductions have to be made from the total areas by reason of inaccessibility or the character and size of the trees. It is estimated that, of the Canadian forest area, only 292 million acres out of 770 million carry merchantable timber, and only 154 million acres saw-timber. The United States total of 550 million acres comprises 138 million acres of virgin forest, 250 million acres which have been cut over and culled but are reproducing timber, 81 million acres which have been logged, burnt and left barren, while 80 million acres are open forest of scrub trees. The commercially useful timber in Alaska appears to be confined to the two National Forests of approximately 20 million acres, while 49 million acres in Mexico have been classed as timber forest. From these figures a total area of effective forest of 750 million acres is obtained. This is equivalent to approximately 6 acres *per capita*.

STAND OF TIMBER.

The quantity of timber standing in the forests of North America has been estimated at different times by the various forest services. It would appear to be between 1,100,000 and 1,200,000 million cubic feet, of which 65% to 70% is in the United States and 20% in Canada.

THE DRAIN ON THE FORESTS.

In addition to the wood which is removed from the forests for use, viz. for manufacture into lumber, pulp and paper and for fuel, enormous quantities are destroyed annually by fire and the ravages of insects and fungi. Estimates have also been made, as for the volume of standing timber, of the quantities of wood removed annually from the forest by all these agencies. The latest figures compiled by Zon from estimates made by the different forest services indicate that the total volume is in the neighbourhood of 32,000 million cubic feet annually. On this basis, if there were no growth at all, and all the wood were accessible, it would all be used up in approximately 35 years. Put in another way, one can say that if the rate of growth averaged 3% all over and the timber were all accessible, the consumption could go on indefinitely. As will be seen later, the latter assumption appears to be very wide of the mark. Of the total amount of wood removed from the forest, approximately 28,000 million cubic feet are cut for use, while 4,000 million are destroyed by fire, insects and fungi. Of the cut, the United States forests furnish 24,300 million cubic feet or 87% and the Canadian forests 2,616 million cubic feet or less than 10%. In the United States rather more than 50% is softwood, and in Canada more than 90%. Fuel wood accounts for 43% of the United States cut and 30% of the Canadian. For pulp there are cut annually in the United States forests 4½ million cords, and in the Canadian 4 million cords, equivalent in all to 1,000 million cubic feet of standing timber. Vast as the pulp and paper industry is it consumes only from 3% to 4% of the total cut.

As regards losses from fire, insects and fungi, any estimate must necessarily be subject to considerable margins of error. Forest fires burn over, on the average, about 10 million acres per annum. The Eastern forests in particular have suffered severely from insects and fungi. The larch saw-fly practically wiped out the mature larch some 30 to 40 years ago, a recent attack of spruce budworm has killed huge quantities of balsam and spruce, while the chestnut disease, introduced from Asia, is proceeding to wipe out one of the most valuable species in the United States. In all probability, therefore, the estimate of 4,000 million cubic feet losses which I have stated above, is not seriously over-stated. It represents from six to seven times the total amount of wood used annually in the United Kingdom.

TRADE IN TIMBER AND PRIMARY WOOD PRODUCTS.

Of the total volume cut in the forests some 570 million cubic feet have been exported per annum in post war years from the country of origin. The corresponding import amounts to approximately 400 million cubic feet, so that on balance North America appears to be exporting to the extent of about 170 million cubic feet. For various reasons, which I need not detail, it is impossible to be precise. The figure quoted, though great in itself, is relatively insignificant when compared with the total consumption.

EXTERNAL TRADE.

Not only Britain but Western Europe generally in the past have made great demands on North America for both special and general utility timbers, while the tropical and Southern American countries have been almost wholly dependent on the North for building timbers. From the Pacific coast shipments of Oregon pine have been made for many years to Australia and the East. With the opening of the Panama Canal, the Pacific timbers have come in increasing amounts to the Eastern American markets and to Europe. The trade with Australia, Japan and the East generally is also expanding.

INTERNAL TRADE.

There is a great and rapidly growing movement of wood products within the Continent itself. Broadly, this takes the form of the transport of softwoods from the West and South to the industrial regions of the East, of softwood building timbers from the West to the Prairies, of hardwoods and large-sized structural timbers from the South to Canada, and of pulp wood and small dimension softwoods from Canada to the Eastern pulp mills and manufacturing district of the United States.

UNITED STATES.

Exports of lumber reached their maximum in 1913 at approximately 285 million cubic feet, but declined in 1920 to approximately 165 million cubic feet. The United Kingdom and Canada are the best customers in this trade. On the average of the 5 years, 1909-1913, the former took nearly 40 million cubic feet, valued at nearly £4 million, as well as wood manufactures, valued at just over £1 million. In 1922, the comparative figures were 22 million cubic feet, £4.9 million and £1 million. On the average of the 5 years, 1910-1914, Canada took 53 million cubic feet, and in 1915-1919, 25 million cubic feet. The total export of timber fell in the second 5 years period to 50% of the first. After the United Kingdom, Canada and the West Indies, South America and Australasia have been in order, the biggest consumers. For the last year or two the West Indies have been the largest customers. The most striking feature of the United States export trade is the decline of trade with Europe since the war.

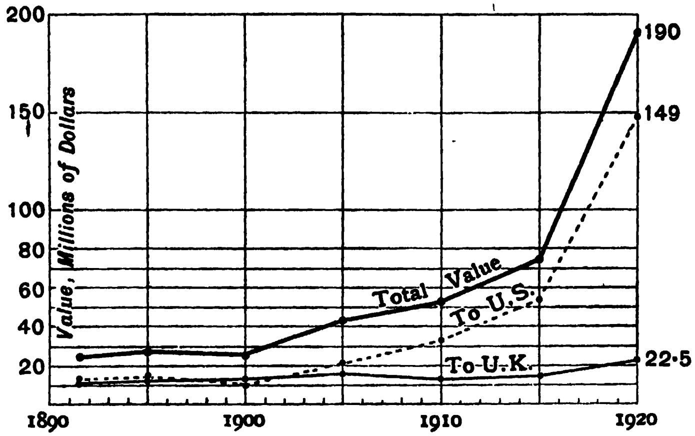
The United States imports consist of hardwoods and softwood constructional timber, and cordwood, of which the last two come almost entirely from Canada. In 1920, the total import of timber was approximately 150 million cubic feet, of which the hardwoods, amounting to about 7 million cubic feet, came chiefly from the West Indies, Central and Southern America.

CANADA.

Exports of wood and timber on the average of the years 1919-1922, amounted to approximately 295 million cubic feet. The most considerable single item was 1,105,000 cords of pulp wood, all of which went to the United States.

In addition to wood and timber, there were also exported annually, manufactured wood valued at $3.2 million, wood pulp, $52.3 million, and paper $74.3 million, the total exports being valued at $226.7 million as against $31.2 million imports. Imports were made up of unmanufactured wood and timber, $13.0 million; manufactured wood, $6.6 million; wood pulp, $1.6 million; and paper, $10.0 million. The imports of timber consisted chiefly of hardwoods and sleepers.

The United Kingdom and the United States are the chief competitors for Canadian forest produce, but the latter are rapidly displacing the former. The diagram below illustrates this movement very clearly.



Canadian Exports of Wood, Wood Products and Paper.

As in the United States, the West is developing its export trade in timber; British Columbian water-borne exports increased from upwards of 9 million cubic feet in 1919 to nearly 23 million cubic feet in 1922, in which year the United States took nearly 7 million cubic feet, Japan 6 million, Australia and New Zealand 5 million.

NEWFOUNDLAND.

The bulk of the timber cut in the island is consumed locally, the items of export in 1922 being pulp 20,000 tons, and paper 35,000 tons, which were sent to the United Kingdom.

MEXICO.

The Gulf forests of Mexico for a very long time exported important quantities of mahogany, cedar, logwood and dyewood. Zon estimates the total average pre-war exports at about 5 million cubic feet, of which rather more than 50% went to the United States and rather less than 50% to Great Britain.

In 1913, Mexico sent nearly 5 million cubic feet of sawed lumber to the United States. On the other hand, there is a considerable import of softwoods, including railway sleepers, amounting to perhaps 15 million cubic feet from the United States.

FOREST EXPLOITATION.

I will now ask you to follow me in a closer enquiry into the effect of all this on the forests themselves.

In the United States, the procedure in forest exploitation has been to concentrate on one, or at most two regions at a time. The capital invested in sawmilling plant is comparatively small, and the sawmiller has been able to follow up the retreating forest. For this and other reasons, it has paid him best to work with large and often wasteful units. The pulp and paper mills which entail far greater initial outlay in plant and buildings are less mobile, and, as we shall see later, failure to maintain the forest in a productive state is leading to difficulties.

THE NORTH-EAST STATES.

The story of modern forest exploitation begins with the North-Eastern States, which until about 1870 provided the bulk of the lumber supply of the whole of the United States. There were originally over 108 million acres of forest from which most of the original pine, spruce and hemlock have been cut. These States can now supply only 30% of their own requirements of timber. On the other hand, a vast pulp and paper industry has been set up with a capital investment of $565 million, producing 53% of all the paper manufactured in the United States. There is a heavy import of pulp wood from Canada to keep the industry going.

THE LAKE STATES.

From about 1870 onwards, these States became the leading timber-producing area, vast quantities of white and red pine being shipped away. Hemlock and hardwoods are now the chief timbers, and Michigan, Wisconsin and Minnesota depend on outside sources for 47% of their consumption of timber.

The pulp and paper industry consumes over 1,100,000 cords of wood per annum, and the problem of securing a continuous supply is very difficult. There are in these States 20 million acres of denuded and burnt over land which are practically barren.

THE SOUTHERN PINE REGION.

After the Civil War exploitation began on a considerable scale, but it was only when the Lake States production began to decline, about 1890, that production on the grand scale started, reaching a maximum of 1,400,000,000 cubic feet, or 8,500,000 standards in 1909. The cut is declining, and in 15-20 years the virgin stands will be worked out. Our enquiries point to the lower figure, and one of the largest milling companies is preparing to turn over to pulp-production within that period. Production by modern mills is extremely rapid ; a single mill which was visited consuming per diem 60 acres of mature forest, and turning out 500 standards of timber. As in the Lake States, enormous damage has been done by fire, and there are upwards of 30 million acres of denuded land in this region. When the Southern pine has been cut out, some substitute will have to be found for pitch pine, which is the standard timber for heavy construction work in many parts of the world. Intimately allied with timber supply is the Naval Stores industry, which has an annual output exceeding 40 million dollars. Three-quarters of the world's supply of turpentine and rosin is produced here.

CENTRAL AND SOUTHERN HARDWOOD REGION.

The original forest area amounted to 339 million acres, but has now been reduced to about one-third (124 million). Much of the forest in the Mississippi and tributary valleys was on rich agricultural land, and has been cleared for farming. The forests in the Southern Appalachians have been severely culled, and chestnut blight has done a great deal of damage. There is, however, considerable second growth. The last great reserves of virgin hardwood forest are in the delta of the Mississippi. This region uses 46% of the total lumber consumption of the United States, and has to import 60% of its requirements.

THE ROCKY MOUNTAIN REGION.

There is a great area of virgin coniferous forest (some 38 million acres), in addition to some 25 million acres which has been burned (chiefly) or logged. The forests are difficult of access for topographical reasons, and the region at present actually imports 50% of its lumber.

THE PACIFIC COAST REGION.

This region contains the last accessible reserve of virgin softwood in the United States. There are still some 40 million acres of virgin forest, the bulk of which, together with some 15 million acres of cutover land, will never be used for agriculture. The region produces about 31% of the United States timber cut, and production is rapidly increasing as the Eastern and Southern forests are worked out.

The position with regard to the supply of wood and timber in the United States may be summed up thus : Softwood saw-timber is being cut 8½ times as fast as it is growing, hardwood saw-timber 3½ times as fast. Including all kinds of wood, one quarter of the current cut is replaced by growth and three-quarters are a drain on capital. The consuming industries are situated for the most part in the east and north-east, where the forests have been pretty well depleted. Local supplies are quite inadequate and the deficit has, therefore, to be brought from the Southern and Western forests and from Canada. In 1920, the cost of transport alone amounted to $250,000,000, the amount moved being one and two-third million carloads, and the average haul 485 miles. Timber is now being shipped from the Pacific to the Atlantic Coast at a freight cost of $30 to $32 per standard, and railed from West to East at $50 per standard. The pulp mills of the North-Eastern States find it increasingly difficult to work to capacity, and in some cases have to transport cordwood several hundred miles by rail ; the average cost at the mill being $19 per cord.

CANADA.

The Dominion Forestry Branch (Craig), estimates that on 60% to 65% of the forest land the timber of commercial size has been cut or burned—chiefly burned. In the East, the accessible forests have been culled, first for large white pine, and secondly for large spruce. The result is that one has to get far from the beaten track to see large trees. From the published figures there appears to be a distinct tendency for the production of timber to decline, and, as in the United States, for the centre of production to shift westwards—to British Columbia. On the other hand, the Eastern pulp and paper production has increased by leaps and bounds. In 1908 there were cut 1,325,000 cords of pulp wood, of which 483,000 cords were used in Canada; in 1920, 4,025,000 cords were cut, and 2,777,000 cords were used in Canada.

ALASKA.

The production of timber is slight, but in the last year the National Forests have been opened up to pulpwood operations, and it is anticipated that in due course a great pulp and paper industry will be built up on a permanent basis.

MEXICO.

The Mexican forests have not yet received the systematic attention of large scale operators. Large mills were erected some years ago in the North but were destroyed in one of the periodic revolutions.

FORESTRY IN NORTH AMERICA.

Forestry in North America has been a plant of slow growth. With so vast an area of forest it has been difficult to bring public opinion to realise that the timber supplies are not inexhaustible and that action is necessary.

In the United States the forests were disposed of to individuals at an early stage. Of late years large areas have been re-acquired by the Federal Government, largely during the Presidency of Mr. Roosevelt, and by the individual States. Of the total area 98 million acres are now in public ownership, 221 million acres belong to timber companies and other commercial organisations, and 150 million acres are in small parcels (woodlots) attached to farms. The public forests include nearly 78 million acres of National Forests and Parks, which are, however, to a great extent at the headwaters of navigable streams in the Rockies (mainly), and elsewhere, and consequently are not easily accessible. They are being gradually opened up and placed under systematic management. The different States own about 7 million acres.

In view of the devastation which private ownership has brought about in the States the Federal Government is retaining the commercial forest areas in Alaska, and proposes working them in such a way as to ensure continuous production.

In Canada and Newfoundland the forests for the most part have not been alienated from the State. The practice, mainly, has been to retain the freehold, and to lease the timber for exploitation by commercial companies. In this respect Canada is more fortunately situated than the United States, since the Governments retain the power to enforce rational forest management whenever that course becomes economically possible. In all, about 157 million acres have been set aside as Dominion and Provincial Reserves and Parks, but at present very little has been done in them to ensure continuous supplies of timber.

The conditions in Mexico during the last few years have not been such as to encourage the practice of forestry.

Generally the immediate forestry problem in North America is to secure adequate protection against fire. If this could be secured, natural regeneration, which is good in most regions, would go far to restock the forests as they are cut. But natural regeneration, to be really successful, requires regulating, so that the most useful species may be secured, and as a rule some measure of assistance in the form of planting. These are the first stages in systematic silviculture, and so far they have received very little attention.

The area which is being planted per annum in North America is under 40,000 acres, which is not double the amount done in Great Britain. Keeping in view the vast areas which can be restocked with useful species only by planting, the effort is quite inadequate. There is, however, a growing interest in the subject, not only on the part of Governments, but also pulp and lumber companies. It is realised in fact that prices of forest products are advancing to, if they have not already reached, the point where they will repay the cost of production.

A word must also be said as to the extensive research work which is being carried on in the United States and Canada on timber growing and utilisation. The results are not only of immediate practical utility, but will also prove of great value when silviculture comes into its own.

THE FUTURE.

It seems clear that there must be considerable stringency in supplies of forest products in the United States within the next twenty or thirty years. Consumption *per capita* of timber over the last 50 years is fairly accurately known. In 1850 it was under 20 cubic feet, but increased at a fairly steady rate until 1909, when it reached 40 cubic feet. Thereafter it fell rapidly to 26 cubic feet. This figure is to be compared with a United Kingdom consumption of 9 cubic feet *per capita* in 1922, and 12 cubic feet on the average of the 5 pre-war years 1909-13. The total *per capita* consumption of wood in the United States, however, is 228 cubic feet, so that if effective economies are to be made, they must be applied mainly to such products as fuel wood and round timber and in the conversion of round timber to lumber. In the last there is, indeed, ample scope for improvement. One can forecast with reasonable certainty that while *per capita* consumption will continue to decrease and population to increase, the total consumption will not be easily reduced until prices go much higher than at present. It seems fairly clear also that the North American continent will absorb all the forest products it can produce, and the considerable excess of exports over imports of softwoods and hardwoods will shrink to negligible proportions or be replaced by an excess of imports over exports. It is quite possible, in fact, that the Eastern States may become competitors with the United Kingdom and Western Europe generally for the softwoods of Northern Europe. This might become a serious matter for the United Kingdom, since the permanent exportable margin from N. Europe is not capable of very great expansion. As regards hardwoods, increasing demands will no doubt be made on tropical forests.

It is clear also that the world's supply of really large softwood timber will be practically worked out within the time I have mentioned, when the accessible virgin forests in North America will mostly have been cut over.

Ultimately North America, like Europe, and indeed the rest of the world, will have to rely on the products of cultivated forests. We are now at the beginning of that stage in the history of the North American forests. The Report of the States Senatorial Committee, to which I referred in opening, indicates that vigorous action may be taken in the United States. The Silvicultural Committee of the Empire Forestry Conference pointed out also that the time is ripe for action in Canada.

CONCLUSION.

Apart from the absorbing interest attaching to the use which the North American continent has made of its primeval forest resources, my subject has very practical bearings on the United Kingdom. We ought, in the first place, to be paying more attention to the forests in our tropical colonies, which can probably provide efficient substitutes for hardwoods at present obtained from America. In the second place, one of our sources of timber supplies is failing. We can therefore go forward with our forest policy in full confidence that it will be a good national investment. That at least is the main conclusion which the Forestry Commissioners draw from their study of the Forests and Timber Supply of North America.

DISCUSSION.

THE CHAIRMAN (Lord Clinton), in opening the discussion, said the author had put before the audience a large number of facts and figures which were of the most important nature, to a few of which he himself might draw particular attention. The author spoke of the forests of the North American continent in terms of millions of acres, or hundreds of miles. That did not convey very much to one's mind, but the important fact which the author had shown was that only a comparatively small amount of that great forest area was in any way merchantable or marketable. Out of the 770 million acres of timber in Canada, for instance, only 154 million acres, or one-fifth, were ever likely to reach the market. Presuming the same sort of figures applied to the timber area in the whole of the North American continent, it was quite certain that with the enormous amount which was now consumed by that continent itself, and by those countries which imported from it, that area could not for very long stand the strain. That idea was enforced by the statement that in the United States alone they were so eating into the capital of their timber that the amount of produce removed from their forests was no less than eight-and-a-half times their growth. Statements were heard about single mills in the United States having a daily consumption of 60 acres of timber. Under those circumstances it was certainly not surprising to find that many of those States, like the North Eastern States and the Lake States, which at one time comprised the great timber belts of the southern half of North America, were no longer self-supporting and had to import the bulk of the timber which they used. It was stated also that in the Southern pine belt, the period of life in the virgin forests was not more than 25 to 30 years. In spite of that enormous drain upon the capital of the timber supply, apparently very little was being done to make it good. The young growth was too often burnt over, and the amount of artificial planting done was so small throughout that great area that it was barely equal to about double what was done in this small country of Great Britain. In addition to great consumption, there was fire and pestilence, so it was not surprising that those forests were rapidly disappearing. It was almost surprising that trees were able to be grown at all. He would like to ask the author one question. The author estimated that, while the total amount of timber used would undoubtedly increase in the future, he apparently was of opinion that the amount of timber used per head was likely to decrease. For the last half a century everybody had been somewhat surprised at the fact that, in spite of the very large number of substitutes for timber, the amount used per head had always been increasing. It had increased right up to the date of the outbreak of the war. It was quite true that since that date it had decreased very largely, both in the States and in the United Kingdom, and probably throughout the world, but that was due, one would imagine, much more to external conditions, such as bad trade, collapse of the exchanges, and other things, than to any economy which had been effected, or which was likely to be effected in the ordinary use of timber throughout the world. It might affect estimates very largely indeed if it were possible to show that the economies which could be employed in the use of timber might eventually so far affect the supply that the life of these great forests might be longer than anybody at the moment anticipated.

The effect of the drain on the timber forests of the world upon this country naturally had to be considered. It was upon timber that industries throughout the world had been started, and it was upon timber that they very largely flourished. It was of desperate importance to us to form some real idea of what was to be done here or elsewhere when the forests of the world were exhausted, or when that much earlier period arrived when the nations and countries which had those forests would require the whole production for their own internal uses. It all pointed to the fact, which he desired to emphasize, that, in this country, at all events, the State itself was bound to look forward and see what could be done for the future of its industries before it was too late. It was perfectly clear to him personally, as a forester, and should be clear, he thought, to those who had charge of the affairs of this country, that in order to put the future in as good a position as the present, it was essential that the State should continue its forestry operations on a much larger scale than it was doing at present.

The soft wood supply was a great difficulty. He was not certain that the hard wood supply would not be in the near future one of greater difficulty. The oak supply of this country was essential for the needs of a great number of our industries. It could hardly be expected that private individuals would continue planting a tree which, owing to the great length of its rotation, could scarcely turn out to be in any sense profitable. But the State itself should take a very much longer view. As a generation to-day, we were depending upon supplies of timber which had been planted by our predecessors a hundred or a hundred-and-fifty years ago. Without that supply we could not at this moment carry on a great deal of the work which we were now doing. There had been little or no planting for the last 70 years. We were enjoying the goods which a past generation had supplied for us. It was not of much importance to us to-day whether that past generation had made money or lost money over the production of timber. In the same way the State should look forward, and although the Forestry Commission might not be able to show commercially that the planting of oak timber was in any sense likely to be a commercial proposition, yet as we ourselves were enjoying the fruits of what a former generation had done for us, we in our turn ought also to supply future generations with the necessities of their own industrial world. He did hope that the many important matters which the author had stated in his paper would be brought before those who were responsible at the present moment for the finances of the country, and that they would take some guidance from what had been said, and adopt the necessary steps to ensure the future of the timber supply to this country.

He proposed a most hearty vote of thanks to the author for his paper.

Lieut.-Colonel F. D. W. Drummond, C.B.E., in seconding the vote of thanks, said the paper certainly gave one grave cause for reflection. The outlook was exceedingly gloomy, and impressed one with the great necessity there was for the Departments concerned urging, not only upon foreign countries with whom we traded in forestry products, but also upon our Colonies, the great importance of quickly putting their houses in order and doing something to reinstate the ghastly destruction by fire and felling which was going on throughout the great timber areas of North America, Canada and our Colonies generally without replacement. The Forestry Commission was doing magnificent work, and the people of this country could not be too grateful to them for it. It was to be hoped that the Government would be impressed with the work of that Commission and further encourage it with sufficient finances to enable it to do more extensive work.

Mr. Loren L. Brown, Timber Commissioner, British Columbia, said there was another gloomy point which he could add, and that was in regard to the timber coming from the region of the Pacific coast. When those forests were cut down there would never again be timber like it. The world would not be able to wait two or three hundred years for such trees to grow again, and people would have to satisfy themselves with a very low grade of soft wood lumber.

MR. J. S. CORBETT, Secretary English and Empire Forestry Association, said the author had referred to the consumption of timber for pulp. It had occurred to him to wonder whether, if those areas in the United States, Newfoundland and Canada were left, they would eventually be able to grow merchantable timber. He did not know what the species were which were usually converted into pulp wood, but there did seem to be a possibility of salving some of that timber if other material could be found within the Empire (and he believed there was other material within the Empire) which could take the place of the timber which was at present being used for pulp.

COLONEL G. L. COURTHOPE, M.P., desired to say how pleased he was that the Royal Society of Arts had opened its doors to such a paper as that which had been given that evening, because he had been very much perturbed of late at the lack of interest, and at the lack even of attempts to excite interest, in the very serious problem of the timber supply of the future. The author had clearly satisfied everybody that in a very few years Europe must not expect to get any timber from North America at all. The story, however, did not end there. Those who were familiar with the report of the British Empire Forestry Conference held in Canada last Autumn, would probably recollect a very interesting paper by Prof. Fraser Storey, in which he gave a table of figures of the production and consumption of softwood timber in Europe, from which it appeared that the rate of consumption exceeded the rate of production by something like three and a half thousand million cubic feet a year. At that rate of consumption there would be no softwood left at all at the end of something like 70 years. What did that mean ? It was easy to say " We shall arrive at a stage before very long when countries will get frightened and begin to cultivate their forests and reduce waste and effect economies, and so on, and things will get better " ; but it took generations after a country began to cultivate its forests before it could supply the commercial demands for timber, and during the hiatus of two or three generations the world was going to suffer acutely owing to a shortage of commercial timber. The time was not very far distant when not only commercial softwood would become very expensive, but also unobtainable. Directly exporting countries realised the danger of the present rate of exhaustion they would place restrictions upon exports, and we, in this country, to whom imported timber was more important than to any other country in the world, would suffer. It might easily be found within the next generation or two that commercial softwoods, which we were accustomed to regard not only as an essential of our existence, but as an inexhaustible essential, would be unobtainable at any figure which we could afford to pay. It behoved the professional organisations to do all they could to rouse public opinion on the matter so that remedial measures might be taken at the earliest possible date. The British Empire possessed great forests as to the contents of which hardly anything was known at present, and it was quite time that we began to learn a great deal more about what was there, the uses to which they could be put and to what extent some of the tropical hardwoods, which were hardly ever used now for commercial purposes, could be used in substitution for the commercial softwoods upon which we were now accustomed to rely. There were many other lines of investigation and research which ought to be started at once. All that was necessary was to rouse public opinion, and he hoped the author's paper would mark a red letter day in that direction.

MR. D. MCVICAR (Western Australia) said they, in Western Australia, had started a very intense propaganda on the subject of timber supply within the last two or three years. They were trying to indicate to the people there that the forests did not belong to the present Government, or to any Government, but to the people. Necessarily, if the forests belonged to the people they should be protected by the people themselves. Until 1918 Western Australia had no Forest Act ; all revenue derived from forests went direct into consolidated revenue. From 1919 three-fifths of the net revenue was put back into the forests. Australia had been cutting her forests for the last 40 or 50 years. In Western Australia to-day they were cutting at the rate of 800,000 loads of timber. The forests were making 250,000, so one could see how they were encroaching on capital. They were finding it very hard indeed to get a sympathetic hearing, and also to get money. Forests could not be grown without money ; and unless that money was obtained timber would be short. In Western Australia there were 640,000,000 acres of country and 350,000 people. If that territory was peopled, Western Australia would require all its own timber. The Forest Department there was doing its best to regenerate the forests. The silvicultural work had only been started since 1919. It was, however, going ahead and they hoped to do better. They wished their parent Association in this country all luck in its work.

The vote of thanks was then put and carried unanimously.

MR. ROBINSON, in reply, said there were two points to which he had been asked to reply. The first was the Chairman's point that the consumption of timber tended to increase per capita. That had undoubtedly been the case in this country where it had increased three-fold in the last 70 years. Our consumption per capita, however, was in the neighbourhood of about 12 or 13 cubic feet. In the United States it was now in the neighbourhood of 26 cubic feet. If we could live on 12 cubic feet the possibilities were that the United States people could live on less than 26. The actual course of lumber consumption per capita in the United States had gone in the following way. In 1850 it amounted to 20 cubic feet per head. It grew steadily, until, in 1909 it was 40 cubic feet. Then it had fallen until at the present time it was 26 cubic feet. Actually the great saving to be made was in regard to waste.

Mr. Corbett asked the question whether the pulp wood being cut in Canada could grow into merchantable—by which he presumed Mr. Corbett meant saw-timber. Personally, he thought quite a lot of it could, but it would not. The white spruce easily got to be a saw log size. The black spruce was a doubtful tree which rarely got to much more than 8 or 9 inches in diameter. As to whether the bulk of the Canadian pulp would ever be allowed to grow into saw timber he thought the answer was pretty clear.

The Chairman, in closing the meeting, said he thought Mr. Robinson's paper would be a great addition to the literature upon the subject of North American forests. He might also be permitted to thank the Royal Society of Arts for inviting Mr. Robinson to give his lecture, thus showing their interest in the very important matter of forestry.

The meeting then terminated.

CORRESPONDENCE.

NEW USES FOR RUBBER.

Owing to an alleged obscurity in my definition of the desirable size of rubber blocks for road paving in the *Journal* of April 4th (page 340), I think it advisable, to add these particulars:—Taking, for example, the thickness of the rubber block as 3 inches, the width should be 6 inches and the length 9 inches.

D. R. BROADBENT,
A.M.I.E.E., A.M.I.M.E.

GENERAL SHORTREDE'S LOGARITHM TABLES.

Our senior partner, a Fellow of your Society, has drawn our attention to the remarks made by Mr. A. R. Hinks, C.B.E., M.A., F.R.S., Secretary of the Royal Geographical Society, and reported in your *Journal* of February 8th, page 204, with respect to the Logarithm Tables of the late General Shortrede, which we publish.

As the information given by Mr. Hinks was quite new to us, we communicated with Mrs. Shortrede, the daughter-in-law of the late author, and her son, Lieut.-Colonel Edward G. Cheke, F.R.G.S., has supplied us with the following very interesting note:—

"General (then Major) R. Shortrede calculated his Logarithm Tables 'in the sublime solitude of the Western Ghats' during his spare moments, while he was carrying on that section of the Trigonometrical Survey of India. I have *never heard any mention* of the '18-inch Theodolite being dropped off a tower'—and even if it were a fact I do not quite see how that would cause him to spend a considerable portion of his time in the Ghats. On his return from India, General Shortrede took up his residence at Blackheath, where he went through all his Logarithm Tables again—without finding one single inaccuracy. General Shortrede always laid claim to have been the first person to determine the *height* of Everest—and thereby established it to be the highest peak of the Himalayas. The statement that the height of Everest was determined in the Survey Offices in Calcutta is a pure myth."

As General Shortrede's Logarithm Tables continue to be widely used, you may think with us that the correction and information given now is of sufficient historic importance, to justify the insertion of our letter in your journal.

CHARLES & EDWIN LAYTON.

NOTES ON BOOKS.

The Yearbook of the Universities of the Empire, 1924. Edited by W. H. Dawson and published for the Universities Bureau of the British Empire. London: G. Bell and Sons, Ltd. 7*s.* 6*d.* net.

There are now 67 universities in the British Empire, and their united calendars contain about 50,000 pages. Probably no library except that of the Universities Bureau contains them all: hence the usefulness of a volume like this in which such information is extracted as is likely to be of use to members of universities and colleges, government departments, clubs, schoolmasters and the public generally. A full list is given of the teaching staff of each university and brief accounts of the equipment in libraries, museums, laboratories, etc., and of the degrees, diplomas and certificates which it confers, while further sections deal with fees, scholarships, numbers of students, etc. A full index adds to the value of the volume.

We have made numerous tests of the accuracy of the information contained in the book and have found it invariably reliable.

ADVISORY ART COMMITTEES:

A SUGGESTION TO CITIES, TOWNS AND RURAL AREAS.

There have been, in recent years, encouraging signs of increased interest on the part of the general public in questions relating to the preservation and increase of the general artistic and natural amenities of towns and rural areas. Expression of this view is also shown in a desire to preserve the fine works of past ages, while the universal approval with which the recent appointment of the Fine Arts Commission has been received, and the formation of similar Committees of taste which had preceded it in more than one provincial centre, clearly shows the increasing interest which is being taken in civic development generally, and the desire for its treatment from the æsthetic as well as from the purely utilitarian standpoint.

The Royal Institute of British Architects is anxious to encourage these tendencies, and invites the co-operation of those actively interested to secure that in the march of progress the claims of beauty are not forgotten. As a means to this end it suggests the formation of an Advisory Art Committee in towns and rural districts, with the object of affording advice in a consultative capacity in all matters concerning the amenities of the district, including questions relating to the preservation of old buildings, the lay-out of new streets, open spaces, cemeteries, designs for proposed new public buildings, bridges, monuments or memorials, fountains, public means of lighting, fences, public conveniences, or other structures to be erected upon land belonging to or under the control of the Local Authority, that may be referred to the Committee, or as to which it may desire to give advice.

The constitution of the Committee which is suggested will vary according to local circumstances, and will differ in urban and rural areas. In many towns Civic Associations already exist, and the influence which these or similar organisations possess may suitably be employed to foster the establishment of an Advisory Art Committee. In smaller localities the machinery of the Local Ratepayers' Association might be used. For example, there already exists in one London district such a Committee of the Ratepayers' Association, which is doing most useful work in safeguarding the amenities of its own district.

The findings of the Committee should be in the nature of recommendations only, and it may be necessary that all such matters as may be considered by it should be treated in strict confidence, and not be divulged except by agreement with the Local Authority concerned.

It is essential that such a Committee as is suggested should be representative of real artistic competence and judgment (though not necessarily of the purely professional kind), and that its members should be persons whose opinions are likely to command public respect. The cultivation and preservation of harmonious relations with the Local Authority is of the greatest importance, and the best means by which this end may be attained requires the most careful consideration.

The Royal Institute of British Architects, while not presuming to dictate upon the question of the constitution of Advisory Art Committees, will be glad to offer advice and such information on the subject as they possess, if required to do so.

NATIVE INDUSTRIES OF TUNISIA.

The following particulars of the native industries of Tunisia are taken from the recent report on the trade of the Regency by the Acting British Consul-General at Tunis:—

Pottery.—Both in Tunis and in the inland districts quantities of unglazed, somewhat rough pottery are made, principally for local domestic use. A certain quantity, however, of the better varieties is exported.

This pottery is very picturesque but extremely fragile, so that the consumption of it is greater than would be the case otherwise. In the native inns and drinking houses stacks of shallow drinking bowls are to be seen, and it is to be presumed that the customers break a good many, and so keep the potters busy.

In the hot weather there is a great demand for the deep native porous pitchers in which, owing to the rapid evaporation, water keeps surprisingly cool.

This kind of pottery is very cheap; a drinking bowl costs only the equivalent of an English penny.

A charming glazed and coloured pottery is also made, of far higher quality, principally at Nabeul. This is very artistic and is much sought after by tourists, who, however, being unversed in oriental methods, are made to pay at least double the current price. In fact, it is usually cheaper to buy the Nabeul pottery from the large general stores in Tunis at retail prices than at the factory at Nabeul at so called "semi-wholesale" prices. A visit to the factories is, however, most interesting.

An increasing amount of this pottery is exported. The total exports of Tunisian pottery of all kinds in 1922 amounted to about 437 tons.

Leather Goods.—In Tunis and other centres, notably Kairouan, the holy city, a certain quantity of very cunningly-worked fancy leather goods are made by hand, including bags of all sizes, both plain and worked with silver thread, purses, wallets, belts, cushions and mats, all of very oriental design. The output is limited, and no attempt appears to be made to increase it by methods of division of labour or other more modern devices and labour-saving instruments. This is typical of the Arab mind, but it is probable that the goods are all the more artistic and curious.

Although these leather goods can be bought at many of the larger stores, the more interesting kinds, as well as the standard patterns, can be purchased to greater advantage in the "Souks," namely, the native shops of the Arab quarters. This is a somewhat lengthy process thanks to the need for bargaining.

Owing to the difficulty of obtaining these goods in sufficiently large quantities, the exports are relatively small, the total for 1922 being 44 tons.

Native stuffs, carpets, blankets, fez caps.—The stuffs comprise highly-coloured shawls and sashes of oriental pattern, now somewhat in demand in Paris owing to the fashion for "barbaric" effects in ladies' wear. The local prices appear very moderate to English and American purses. Exports amounted in 1922 to some 30 tons.

Carpets are made principally at Kairouan on hand looms in the native houses. The best wool is used, and the carpets are very heavy and durable. The demand for export is increasing, and as the output remains the same, prices have in consequence risen considerably. Some 18 tons of carpets were exported in 1922.

The output of homespun woollen blankets is very much greater, the principal centre being Gabes; 155 tons were exported in 1922.

With regard to fez caps, it is interesting to note that part of the material, namely, the straw shell or framework, comes largely from Czecho-Slovakia to be worked up in Tunis. Over 20 tons of fez caps were exported in 1922.

GENERAL NOTES.

Cabuya Fibre in Ecuador.—According to the report by H.M Chargé d'Affaires at Quito on the economic conditions in Ecuador, the Cabuya fibre is found abundantly in the mountain region of that country, and grows wild even in the most infertile zones. It is used locally to some extent for the manufacture of carpets, sacks, rugs and rope. Two small installations have been erected at Riobamba for the manufacture of ropes and sacks similar to those made of jute. If this produce were properly developed Ecuador could transform it into one of its chief industries, and provide from its own sources the number of sacks required for her industries, which amounts to approximately two millions.

Water-Power of the St. Lawrence River.—The Canadian Government has under consideration a project for the development and control of the water power of the St. Lawrence River. This involves the construction, with the co-operation of the United States, of a dam control works and development plant at Morrisburg, Ontario, at a cost of from 75,000,000 to 80,000,000 dollars. The installation would produce some 350,000 h.p. for Ontario and a like amount for the State of New York. It is suggested that approximately 15,000,000 dollars, which would be Ontario's share of the cost, should be borne by the Federal Government in compensation for the provision of water control facilities by the province.

Trade in the Gold Coast.—According to statistics published in the "Gold Coast Gazette" Trade Supplement, the total value of the Colony's imports for the first half of last year was £4,748,796, of which £3,411,419 was from the United Kingdom, £116,102 from other parts of the British Empire, and £1,221,275 from foreign countries, the principal contributors being the United States, Holland, and Germany. The total value of the export trade for the same period was £5,582,043, of which £1,899,370 went to the United Kingdom, £196,589 to other parts of British West Africa, and £3,486,084 to foreign countries, principally the United States, Holland, Germany, and France.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings at 8 o'clock.

April 30.—Brigadier-General Sir Henry Maybury, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "The London Dock District and its Roads." Harry Gosling, C.H., M.P., Minister of Transport, will preside.

May 5 (Monday).—T. Thorne Baker, "Photography in Industry, Science and Medicine."

May 7.—J. Robinson, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation." Admiral of the Fleet Sir Henry Jackson, G.C.B., K.C.V.O., F.R.S., will preside.

May 14.—F. C. Ingrams, President of the London Fur Trade Association, "Furs and the Fur Trade."

May 21.—(Trueman Wood Lecture.) Sir William J. Pope, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, "The Outlook in Chemistry."

May 28 (at 4.30 p.m.)—Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Indian Section.

Friday afternoons, at 4.30 o'clock:—

May 2.—Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India." Sir Thomas H. Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S., will preside.

Date to be hereafter announced:—

Bhupendra Nath Basu, M.A., Vice-Chancellor of Calcutta University, "The Vedantic Philosophy of the Hindus."

Dominions and Colonies Section.

Tuesday, May 27, at 4.30 o'clock.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Wednesday, June 4, at 4.30 o'clock.—The Rt. Hon. Sir Frederick Lugard, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates."

Monday, June 16, at 4.30 o'clock.—C. V. Corless, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada."

Journal of the Royal Society of Arts.

No. 3,727. VOL. LXXII.

FRIDAY, APRIL 25, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.(2).

5 JUN. 1924

NOTICES.

NEXT WEEK.

Wednesday, April 30th, at 8 p.m. (Ordinary Meeting). Brigadier-General Sir Henry Maybury, K.C.M.G., C.B., Director General of Roads, Ministry of Transport, "The London Dock District and its Roads." Harry Gosling, C.H., M.P., Minister of Transport, will preside.

Friday, May 2nd, at 4.30 p.m. (Indian Section.) Professor Jocelyn F. Thorpe. C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., "Chemical Research in India." Sir Thomas H. Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

A meeting of the Council was held on Monday, April 14th. Present:—

Lord Askwith, K.C.B., K.C., D.C.L. (in the Chair); Lord Blyth; Mr. A. Chaston Chapman, F.R.S.; Sir William H. Davison K.B.E., D.L., M.P.; Mr. P. M. Evans, LL.D.; Sir Thomas Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S.; Sir Humphrey Leggett, D.S.O., R.E.; Sir Philip Magnus, Bt.; The Hon. Sir Charles A. Parsons, K.C.B., LL.D., D.Sc., F.R.S.; Mr. James Swinburne, F.R.S.; Mr. Carmichael Thomas; Sir Frank Warner, K.B.E.; and Sir Alfred Yarrow, Bt., F.R.S.; with Mr. G. K. Menzies, M.A. (Secretary of the Society), and Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

Lord Askwith was appointed a Treasurer in place of Dr. W. H. Maw, deceased.

Preliminary consideration was given to the question of the award of the Albert Medal for 1924.

The entries for the April section of the Examinations were reported; these are 27,280 as against 22,363 in 1923, an increase of 4,917. Fresh additions were made to the Examinations Committee.

Papers and Courses of lectures for Session 1924-25 were considered.

Other formal business was transacted.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Friday, March 21st, 1924.

Lord Lamington, G.C.M.G., G.C.I.E., in the Chair.

The paper read was:—

PROGRESS OF CO-OPERATIVE BANKING IN INDIA.

By Otto Rothfeld, B.A. (Oxon.), I.C.S.,

Lately member of the Bombay Legislative Council and Registrar of Co-operative Societies, Bombay.

The subject of banking, in other words the mechanism of the economic life of a nation, is so intimately connected with political, social and national conditions that I feel myself obliged to take up your time for some minutes with remarks upon the recent development of India before I approach the subject of the paper more closely.

Within the last twenty-five years that I have myself served in India, that country, if I may call it so, that continent, to be more correct, has changed and is changing so rapidly and in such essential matters, that I find those who have left India only a few years ago are but too apt to fail to recognise the vastness of the alteration.

In a sense, of course, it is as foolish to speak of India as one country as it would be to speak of Europe in such terms. Seen from outside, the difference is as great between the Punjab and Madras as it can be between Sweden and Italy. The differences are not merely those of language; they strike deep into every root of social and economic life. At the same time it has got to be realised that in another sense India is now a united whole. In Europe we are barely conscious of that united life of European idea and custom which does undoubtedly prevail. We see the differences between countries because they are strange; we are blind to the unity because we are so habituated to it, and also perhaps because there is no equal power to set in opposition to its civilisation. There was a time when Europe, or, as it was then called, Christendom, stood for such an idea, but that was in ages when Christendom had to struggle against equal, if not superior, powers of different customs and different religions.

In India there is now such a feeling of national unity. Divergent though the inhabitant of Madras may be from the dweller in the Punjab in every detail of his daily life, yet both of them feel themselves to be in the great sense, men of one country, men of one nation, drawn up in line against opposing powers. There is, therefore, a national India in a very real living sense at this date, though twenty-five years ago such an attribute could not possibly have been predicated. That is the first great change we have to note.

The second great change is more narrowly limited to economic life. For good or for evil it has to be recognised that India has now been drawn into the general economic polity of the world. Twenty-five years ago the Indian district might still be regarded, with some slight exaggeration, as an isolated unit for economic purposes. Within that unit, the people were to a large extent self-subsistent. They produced what they required for their own consumption, and they sold the balance within their district. They depended for comparatively little upon exports from outside. When the rains failed they were subjected to famine, and they often died. Prices being so largely fixed by local conditions varied to an extent which is now almost incredible.

These conditions no longer remain. In India prices are fixed, like the prices of other countries, in the great markets of New York, Liverpool and London. Crops are grown to a preponderating extent for sale in the international market. Cultivation for subsistence is more and more going into desuetude. Since the war we know in Europe how the interests of each one of us is affected by the raids and rapacities of international finance and international commerce. The recent fall and rise of the franc in France supplies an instance in which every man and woman in the country in respect of his or her daily food finds himself successively impoverished or enriched by international capitalist intrigues and conditions entirely beyond his control or that of the mass of the people.

Similarly in India nowadays the livelihood of the humblest peasant is affected by the various moves upon the international chess-board of finance. In that respect, as in respect of internal conditions also, for good or evil, India has become capitalised.

The Presidency of India which has been most rapidly and most completely absorbed into the industrial and capitalist system is undoubtedly that of Bombay. From my own experience I can quote in particular that part of the Presidency which is known as the province of Gujerat. In that province less than twenty-five years ago, on the occasion of a severe famine, the people were still economically so backward that they would not even sell their cattle and that they refused to move a few miles in search of work. It is now an everyday occurrence for the cultivators of that province to take the train to Bombay in order to sell their cotton themselves in the best market; to no inconsiderable extent they speculate in shares; and they watch with eagerness the telegrams from the exchanges of New York and London.

The process is one which in varying degree is going on throughout India. In one part it is less acute, and in another more acute, but the metabolism is taking place everywhere and remedial measures have to be found.

The real question for the statesman and the administrator in modern India is how, given the inevitable capitalisation of the country, the people are to be prepared and protected so that they can enter with success, or at least without too much devastation, into the world of modern economic conditions. The problem is one that touches every branch of Government.

Into the other aspects of the question, however, the problem, for instance, of how to deal with the congestion of the great cities; the problem of how to secure a sufficient standard of education in so vast a continent without overwhelming taxation and too great a waste of time; the problem of undertaking legislation more or less socialistic, it is not the purpose of this paper to enter.

The figures of illiteracy and the really dreadful figures of infant mortality, which in the city of Bombay rise as high as 600 per 1,000, give some measure of the actual situation, and the difficulties that have to be faced. It is undoubtedly true that for various reasons, for all of which the Government of India cannot be blamed, the development departments in the country have lagged far behind, and that India is in consequence handicapped to an extent far greater than was necessary.

This paper, however, is concerned only with that part of development and that side of the problem which deals with the provision of credit and in particular with its provision through and by the co-operative movement in India.

In the widest sense, of course, co-operative banking includes the provision of credit to rural societies and their members. In a sense every society that works in every village and that distributes deposits obtained from members and loans obtained from other institutions among the members for the purposes of cultivation is to that extent a bank, and certainly performs an extremely useful purpose. The object of this paper, however, is not to dwell upon the achievements of the village credit society as such. My intention is rather to present some picture of what has been done by the co-operative movement in the narrower sphere of real banking and especially with the application of co-operation to deposit banking in the modern sense.

Great as is the utility of co-operative credit in the village, managed and governed by the villagers themselves, valuable as it is morally and socially, yet I am inclined to think that in the actual conditions of the more advanced provinces at least, the extension of banking in a more technical sense in the co-operative movement is of a greater importance and of a more lasting value.

To grasp exactly what is being done by co-operative banking, it is necessary to consider first how joint stock banking stands in India. It is hardly an exaggeration to say that twenty years ago banking of any sort simply did not exist in India outside of the Presidency towns. Even to-day joint stock banks outside of those towns exist only in the most insignificant numbers and carry a weight so slight that it can hardly be termed perceptible.

The latest statistical tables relating to banks in India which I have been able to obtain were published in 1922 and are concerned with banks during the year 1920. These tables, which are published by the Government of India, divide joint-stock banks into two classes; those, namely, that have a paid-up capital and reserve of 5 lacs * and over, and those of a paid-up capital and reserve between 1 lac and 5 lacs. The banks that fall into the first class are mainly the Presidency banks, now absorbed in the Imperial Bank, and the Exchange banks.

Exchange banks do a business which hardly touches the average Indian at all. Their main business is the financing of exports and imports and dealing in exchange. The Presidency banks do valuable work for the nation as a whole by acting as treasuries for the Government, but they are so limited and restricted by rules, which are necessary for the safe performance of their primary duties, that they are of little avail to the local trader and still less to the local cultivator.

In the year 1920, including those banks, there were 58 banks in all in the whole vast continent of India. Part of these—the former class of Exchange banks and the Presidency Banks—with a few others, held nearly 11 crores in capital and reserve and 71 crores as deposits.

The second class, which alone can be of real utility to the people of India as a whole, held less than 1 crore in capital and reserve and 2½ crores as deposits.

Without at all touching upon the question of how far the joint stock banks, which fall within the second class, can be considered to be institutions that are fitted to command and deserve confidence, it will at least be obvious that their scanty number, their dispersal, and the smallness of their capital make them practically useless for any purposes of national regeneration or for any influence upon the economic life of the people as a whole.

Apart from these banks, and even including them, it may be asked what conception of banking in practice has found its way among the people. Twenty years ago it may be said that the mere conception of money in the modern sense hardly existed. Even now in most parts of India,

---

* NOTE.—Fifteen rupees may be taken as equivalent to the pound sterling. A *lac* is 100,000 rupees, and is roughly equal to £6,600. A *crore* is ten million rupees and is roughly equal to £660,000.

and by most Indians, the idea of what is meant by money is held only in the vaguest form. Twenty years ago, to the vast majority of Indians money meant simply coins, either in gold or silver. The conception has not been greatly enlarged even to-day, but gradually the promise to pay, endorsed by the Government of India upon paper in the shape of bank notes, has come to be recognised as money of a different form. Even this promise to pay, however, is almost invariably understood to be a promise to give actual coin in exchange when it is required. The underlying conception is that of a Government hoarding vast treasuries of gold and silver coins in boxes, stored upon some remote hill-top, from which when necessary, coins may be drawn to pay the possessor of a bank note.

The fact that money is simply a promise to perform certain services, and a promise drawn upon the capacity for work of the whole nation within a period of years not beyond recognisable limits, and realised when necessary by the imposition of taxation as far as Government is concerned, has hardly yet dawned upon the mentality even of the politician.

It has sometimes been suggested that the money-lender or savkar plays a part in India such as is played by banks in all European countries. This is, however, not the case. He plays no part in regulating industry or commerce, such as is played by the modern banking system in all European countries. Really he corresponds only to the usurer of the 13th and 14th centuries in Europe, and performs much the same service. He lends actual coins at high interest and recovers in coin or in kind. He never looks to the utility or productivity of the loan. He has no wish to direct his finance to any useful purpose. When he is a man of considerable affairs, he also arranges for the transmission of credits by hundi or bill of exchange, usually at high rates of discount. But he does even this by rule of thumb and with little understanding of what actually is happening in the process. And he has always worked with the Government treasury behind him from which, in case of need, he can obtain coined money to meet his promises. It is the Government, or what amounts to the same thing, the Presidency banks acting on remunerative terms as agents for Government which arrange at great expense for the actual transmission of coin.

With your permission I should like here to quote one of my own circulars, which, to the best of my knowledge, summarises the actual position :—

"Economically the greatest evils that India suffers from are insufficient banking and want of proper organisation of capital. Most of the large sums of money absorbed each year by India are hoarded and buried in the ground. By being withdrawn from circulation, these moneys do no good to the country and are even positively harmful. What remains in circulation, is centralised to an unhealthy extent in cities like Bombay and Calcutta. The results are that industries and even ordinary trade outside of those centres languish and are starved, while what industry there is is over-stimulated and congested in two or three cities. . . . . . .

"Furthermore, joint-stock banking has had a slow and halting growth. There are still very many districts in the Presidency in which there is not a single bank in existence. Economic conditions remain mediæval and are more worthy of the times of the Pindari raids than of a civilised country with organised finance. Cheques are not used because they cannot be cashed. Even notes are not yet used sufficiently. One sees constantly a picture, which would be laughable, if it were not tragic in its portrayal of national impotence, of the merchant who carries his chests of silver or gold coin with him in a train or steamer in order to pay his customers in some wretched district which is left without a bank."

It will, therefore, I think, be readily admitted that a first condition for any adequate progress in national prosperity must be a rapid and vast extension of banking within the country. The question that remains is whether it should be left to the enterprise of joint-stock companies to institute such banking, or whether the co-operative movement as such can undertake the task and should be encouraged so to do.

Under the joint-stock system it is clear that all the profit and all the management rests with capital. It is not those who bring business to the bank who profit from its successful working and from their own custom; it is those who have put money into the bank in the form of shares.

Under the co-operative system the opposite is the case. The co-operative method is for members to associate themselves for the advantageous use of the commodities in which they deal—in the case of a bank, the advantageous use of credit—and the co-operative method for securing that the advantage obtained by such combination should be shared by the members according to their own contributions to this advantage, is by having a rule that whatever surplus remains to the society after the payment of its necessary expenses, should be divided among the members in proportion to the business they have done with the Society. This is the co-operative rule which is freely applied in the case of trading societies such as those to which we are best accustomed in England.

In the case of credit societies or banks it has not been easy to apply the rule, but the principle is at least followed of limiting strictly the profits that go to capital, or, in other words, to shareholders. It would also seem to be reasonable that, as the business of the Society has been made by its borrowers and depositors, a proportionate rebate should be given to borrowers, and a proportionate bonus to depositors. It must, however, be confessed that the practice and legislation of various countries has not been consistent on this point.

A bill in the United States legislature makes this distribution of bonuses to depositors compulsory to all credit societies. In France, however, legislation expressly excludes depositors from sharing in the profits while making rebates to borrowers obligatory.

In India the practice has not yet been embodied in law with regard to any class of society. In the case of the Bombay Presidency, however, such a by-law has been included in the model devised for all societies and banks of this type, and is being largely followed. To whatever extent, however, such a rule may or may not be followed at the present moment, it is clear at least that the co-operative bank in all circumstances secures that capital shall have only a limited profit and that the management shall rest with the members who make use of the bank and who, therefore, will take care to insist that its working shall be to their own best interest as customers. This is an advantage at once gained by the co-operative bank over the joint stock bank.

The greater security of co-operative banks, supervised as they are by Government officers and working as they do under strict rule, is another advantage which hardly needs to be emphasised. The constant failures of joint-stock banks in India enforce the lesson. But there is more to be said than that. The existing banking institutions have not been able to develop their business to any appreciable extent even in district towns, and hardly any attempts have been made to provide banking facilities for talukas and their trade centres. Moreover, banks which already command sufficient and extensive business on present lines are disinclined to undertake a banking business with modest beginnings and modest customers in such centres. Moreover, with their centralised machinery, it is doubtful whether they could do so successfully or whether it would be possible for them to buy credit from or give it to small merchants, craftsmen or artisans.

Yet small banking facilities are a primary need of advancing India. The co-operative movement seems predestined to undertake the duty of supplying such facilities and can do so successfully. Co-operative people's banks are admirably suited for tapping local capital and stimulating the free circulation of money and of those rights to action and rights to service which are called credit, for developing local trade and fostering local industries.

The success with which this has been done in Italy is known to all the world. It is less known perhaps that in France also similar success is being achieved by co-operation. Although the law which constituted such banks in France was promulgated as late as 1917, there were already by the end of 1920, 77 such banks in the country with a working capital of about one and a half million sterling.

Such examples are an encouragement to co-operative banking in India. The progress of co-operative people's banks in the technical sense of the word has been most marked in the Bombay Presidency, and I trust you will allow me here to quote remarks made by the late Governor of Bombay, Sir George Lloyd, to whose stimulus and support co-operative banking owes so much. In addressing the Co-operative Conference in 1921 Sir George Lloyd said:—"If co-operators can succeed in establishing institutions of this class honestly working, deliberately seeking to foster the trade and craftsmanship of their towns, and introducing into the humbler homes of the people those banking practices upon which the credit and industry of Western countries is mainly built up, they will, I can assure them, have accomplished a step for the progress and prosperity of India for which a parallel would have to be sought in the first growth of Scottish banking in the 18th century. If they accomplish such a task, I feel certain they will multiply the wealth of the country and increase the comfort of the individual citizen to an extent which perhaps none of us can imagine."

In the previous year, speaking at another Co-operative Conference, Sir George Lloyd had already said that "these urban banks have an increasingly important part to play. As they grow and extend they bring new promises of progress and prosperity to artisans, to the smaller merchants and to local industry, but their utility is by no means confined to the assistance they can directly give to these classes by way of loans and support. A bigger task lies before them. At the present moment, outside of Bombay city, it may be said almost without exaggeration that no banking facilities whatever exist, nor is there any great likelihood that the joint-stock banks will take up mofussil banking to any considerable extent in the near future. The co-operative movement has, therefore, lying before it a virgin field, and I see no reason why co-operative banks of the Luzzati type should not penetrate the whole field and take up the work of supplying this Presidency with the banking facilities which are obviously required for its prosperity."

What I should now desire to do, were it possible, would be to trace in detail the progress made by co-operative banks of this class, namely, true people's banks or urban banks, throughout India. Unfortunately the form in which the statistics and reports of the co-operative movement in India are drawn up, makes it impossible to do so with any accuracy. The statistical tables group banks of this order along with every kind of co-operative society, which deals with persons other than cultivators, and it is not possible to disentangle from the tables to what extent the figures represent banking operations conducted by real co-operative banks.

From individual reports of some of the registrars of some of the Presidencies, information is, however, available. In the case of the Bombay Presidency, for instance, for the last three or four years information has been given in full detail in a separate statement. For the other Presidencies it is known that co-operative banking of this class has been most successful in Burma and least successful in the Punjab. It also appears from an analysis of the general statement, that the banks in the Bombay Presidency have more than one-third of the working capital of such societies and banks throughout India, and that their transactions in this class amount to about one-third of the total transactions in India.

It is allowed by all critics that no portion of the co-operative movement in the Bombay Presidency has been more satisfactory than the urban co-operative banking movement. I venture, therefore, to trouble you with some detailed figures for that Presidency.

In that Presidency societies are classed as urban banks when they have a working capital of over 50,000 rupees and submit financial quarterly statements to Government. Of such banks there are now 31 in the Bombay Presidency. Of these, 15 are pure people's banks of the Luzzati type, open to all persons of every class and caste in the area, and undertaking every form of popular banking. The other 16, although otherwise working as banks, are confined either to a particular community or to persons in a particular kind of employment.

The share capital of these urban banks amounted, at the end of March, 1923, to 18½ lacs and the reserve funds to nearly 4½ lacs. Several banks had to refuse deposits as they could not utilise further funds within their area. In spite of this fact, members' deposits rose to 70 lacs, while another 16½ lacs were held for non-members; 103 lacs were lent during the course of the year; 91 lacs were repaid, and 98½ lacs in all were outstanding at the end of the year. Overdues were 5½% of the working capital.

These figures, taken as a whole, I think, are distinctly promising and shew the importance already achieved by co-operative banking of this class. It may be noted, however, that the turnover is in most cases not sufficiently rapid, while another point that is open to criticism is the insufficiency and underpayment of the staff in many cases. It seems to be difficult for Indian gentlemen to grasp that big business must imply an efficient, honest and contented office establishment. But there are institutions among those banks which, in my opinion, can face comparison with any similar institution in any part of the world. I know at least one such bank in which I am unable to discover any point in which its working is not equal to any Luzzati bank in any Italian city of equal size and importance. These banks are more and more going to use the provincial co-operative bank as a clearing house, and the importance of the provincial bank to the movement as a whole can hardly be over-estimated.

Mention of the provincial bank brings me naturally to the second section of co-operative banking, a section perhaps more urgent at this actual moment to a larger number of people but less important probably in the near future and less interesting intrinsically. I refer by this to the system of agricultural banking which is worked by the district central co-operative banks and the provincial co-operative bank at their head.

These banks lend to societies and not to individuals. In general they lend for a period of one year and sometimes up to periods of five years. In the Bombay Presidency, under a system recently inaugurated, they may even give loans out of funds provided by Government and sanctioned in conjunction with a Government official up to a period of twenty years for permanent land improvements. The loans are always secured on the unlimited liability of all the members of the society which receives the loan. Ultimately the real security is that of the land belonging to the cultivator. The business is, therefore, one of a kind essentially steady and conservative. Their turnover is apt to be slow, their profits can never be large.

The work they do is, however, invaluable. In 1922 there were 473 banks of this class, including provincial banks, in India with a working capital just under 10 crores and a share capital of 1½ crores. It must, however, be remembered that the figures for working capital are inflated, since moneys lent by the provincial banks to district banks appear in both balance sheets.

For India as a whole the turnover was very slow indeed, less than half of the total working capital being lent in the course of the year, and only a little more than one third being recovered. In the Bombay Presidency, where the working of the district banks and the provincial bank follows more closely than elsewhere the working of similar banks in France under the Office Nationale de Crédit Agricole, the figures shew greater banking ability and progress. At the end of March, 1923, there were 20 such banks, including the provincial bank. Including the provincial bank again, the figures of loans made were 1 crore and 48 lacs; their recoveries were 1 crore and 37 lacs; and the outstandings were just under 1 crore of rupees.

These figures shew considerable banking stability in the totals and outstandings as compared with the loans made during the year, and the recoveries received may, I think, compare favourably with most parts of India. They certainly shew that the primary purpose of agricultural banks is being kept well in view.

Excluding the provincial bank, the share capital of district banks in Bombay amounted to 13 lacs in all, and they held 55 lacs in deposit from individuals, and 9 lacs from societies. The provincial bank itself had a working capital of 85 lacs, made up of 18 lacs of non-withdrawable and long-term capital, and 67 lacs of withdrawable capital.

Before leaving the subject of co-operative banking, a few words appear to be desirable in regard to the expansion in the use of cheques and the transactions in bills of exchange conducted by and through the co-operative movement. I believe, though I am not certain, that these branches of banking within the co-operative movement are so far confined to the Bombay Presidency, and it is only in the last three years in that Presidency that they have attained any considerable extension.

I must confess that the figures given cannot be relied upon as being absolutely accurate because of some misunderstandings on the part of banks in filling up their returns. The figures may, however, be relied upon as approximately representing the total transactions. Thirteen thousand cheques appear to have been drawn on or by central banks within the last year to an aggregate value of nearly 5 crores. Urban banks drew or cashed another 5,300 cheques to an aggregate value of 1 crore. Of these there were drawn by individuals against their own accounts cheques to amounts aggregating 29 lacs. In addition some 150 agricultural village societies were reported as having had cheque transactions, the total number of cheques used by them being 4,800 to an aggregate value of 23½ lacs.

The totals in that class of bank and society amounted to 23,000 cheques to an aggregate value of 6¼ crores. Further encouragement to the easy use of cheques has now been given by a concession of Government exempting cheques of members of societies from stamp duty up to a value of 20 rupees. In addition, transactions were reported in bills of exchange amounting to another 14,000 in all for amounts aggregating 1 crore and 80 lacs.

Compared with countries like the United States or even the British Isles, where deposit banking and the use of cheques have been familiar for generations, these figures will, of course, appearin significant. They do, however, represent substantial progress in increasing the money in circulation in the country, and furthering the wealth available at any moment, and they represent also an imponderable advance towards greater familiarity with the meaning of banking deposits and business methods. In the past, with the absence of banks and the practice of hoarding, with the difficulties encountered in the transmission of money and the ignorance of its value and meaning, one rupee in India hardly did the work even of half a rupee. With the freer use of cheques, as now being introduced among the humbler classes of the population, it may be hoped that before long each rupee will, in the course of the day, perform, as in other countries, the work of two or three rupees in adding to the circulating wealth of the country.

I trust the paper I have just read may have been adequate to give some idea of the possibilities of co-operative banking in the great dependency of India, and some idea of what already in the last few years has been attained. What has been attained goes, I think, beyond even what appears from the figures. The encouragement given by urban banks to small traders and artisans can only be measured on the spot, but experience shews that it has been of great importance and that it has restored hope where too often there had only been despondency before.

I can cite, for instance, the community of tailors in the Bombay Presidency as a particular instance. Their caste seized with particular avidity upon the idea of co-operative credit, and has made a beneficial use of it, which has improved their spirit and morale and brought back to their homes many families who had already had to seek refuge and employment in the larger towns. With increased knowledge, the hope of saving and of depositing is fast growing, and a thriftless class is being turned into a class of small capitalists.

The influence of the banks in reducing rates of interest, even among money-lenders, has been openly acknowledged, though it is difficult to chart, especially when world conditions have too often had a counteracting effect. But excessive rates of interest, demanded and obtained in India, imposed a burden almost intolerable upon improved cultivation and upon craftsmanship, and the value of co-operative banks in lowering such rates, not only for their own members, but in the surrounding countryside by their influence, is of immense value for the prosperity of the land.

Most important of all in my opinion is it that, with co-operative banking, we have at least started a system by which the powers of finance, with all that they contain of potentialities for good or evil, may be used by the people, for the people and through the people.

The work that remains to be done is still enormous, and the number of workers is still too few, but with the growing spirit of national feeling and the corresponding gain in self-respect and self-sacrifice, that number, especially among young men who are prepared to devote energy to the task and to perform it with full reliability, is noticeably increasing.

It has been said that every people gets the Jews that it deserves. It is at least as certain that no people can have a co-operative movement which it has not deserved. Unfortunately, even within the limits of the co-operative movement in India, the standard of integrity has occasionally been lower than one would have desired. But I cannot but think that the prospects for the future are bright, that integrity is increasing, and that the desire for national renaissance is providing a stimulus which will urge co-operative banking, like other forms of development in India, forward to a successful career.

DISCUSSION.

THE CHAIRMAN (Lord Lamington) said that it was seventeen years since he left India, and, therefore, he could hardly offer any valuable criticism of the conditions of co-operative banking in that country to-day. When he was there the system was just starting, and from what they had heard from Mr. Rothfeld's paper the Indians were now so far changing their character as to realise to some extent the benefits of co-operation, although formerly each man regarded his own possessions as a talent to be buried in the earth. That was, indeed, a very remarkable change. There was only one question he would like to put. He understood Mr. Rothfeld to state in one passage that the banks were supervised by Government officials. He (the Chairman) did not know to what extent such supervision existed—whether only in certain areas or universally. He would only add that he had read, from time to time, different definitions of the word "money." That evening he had heard a new definition: "Money is simply a promise to perform services." He dared say that there would be other speakers who would have a remark to make upon that statement.

THE SECRETARY OF STATE FOR INDIA (the Right Hon. Lord Olivier, K.C.M.G., C.B.), said that he was present to pick up in the shortest and most up-to-date manner possible the latest information as to the progress of this movement in India. When he was in Jamaica he was very closely associated with one who had a good deal to do with co-operative banks, Sir James Wilson—(formerly Financial Commissioner, Punjab)—and he used to hear of the progress of the movement up to that time from him. Since then he had not heard very much about it. The author had approached the matter from the established and orthodox point of view. He himself, on the other hand, had regarded it rather from the point of view of the people whose needs gave rise to some system of co-operative banking. He would like to know in what proportion the joint-stock banks and other large banks in India were employed for financing Indian commerce, and in what proportion they were employed out of the country. The complaint which used to attach to certain banks in Jamaica was that they were more anxious to receive deposits than to employ money for the development of proper banking facilities in the island. That was a possible complaint which might, in the present disposition of the Indian people, be made against European banks in India, with what truth he did not know, and he would like some information. With regard to banking generally, in which he and many of those present became interested through their old friend, Mr. Wolff, who was present, he spoke as one who had had to do with the administration of a community like Jamaica, consisting of peasant proprietors and produce buyers. At the time of which he spoke these proprietors were always absolutely in the hands of the produce buyers or of the people in the villages who did a little money-lending business, and the result was that when their credit came to an end they were under increasing obligations to the produce buyers or the middle-men. The ordinary banks would not touch that sort of business. It was very difficult in all these communities to induce them to come together and establish a bank. He did not know what the method adopted in India had been, but it might be perhaps interesting if he told the Society very briefly what stroke of good fortune in Jamaica had enabled him to establish a system of co-operative banks there. In 1904 they had a severe hurricane in Jamaica and the coffee, cocoa, and banana plantations all over the islands were severely damaged. In order to resuscitate the cultivation the Government had to make advances to a very large number of small proprietors and peasants. They were able to save the industries and pull them through and get their money back. Two years later they had another hurricane, and the same demand was made upon the Government that they should advance money to small people all over the island. But he declared that he would not finance anybody except through the medium of co-operative banks. The banks were started and had proved a very great boon from that day to the present. The system in Jamaica was not quite the same as the one described by the author of the paper in that the buyer was assigned a share or part of the profits. If they had a loan they must take up so many shares in the bank proportionate to the loan and pay up those shares by instalments. Powers were taken to obtain first mortgage on the lands, and thus absolute security was forthcoming. By paying up their shares the cultivators had completed their obligations. The banks became progressively popular and were managed extraordinarily economically by small local committees. The committees worked voluntarily, and the secretary was generally a local man, who, for a small payment, kept a vigilant eye upon the concern. Then there had to be a central controlling and inspecting board on behalf of the Government. In course of time, no doubt, the system of making the Government the chief banker tended to be superseded, and the central banking was taken over by local banks, which brought the whole of the banking and currency system of the country into one relation. This plan might very likely enable smaller banking centres to be established on which cheques could be drawn. That was one side of the banking progress in Jamaica, that the peasant was emancipated from the produce buyer, but there was another side, about which he had not heard anything that afternoon, the side, namely, of co-operative marketing. On the one side was the producing and the obtaining of facilities for producing, on the other side co-operative marketing, and he wanted to learn something more about this latter. He gathered from the author that the cultivator and others liked to do what all simple peasant cultivators liked to do—to go down and make their own bargain. He felt that to have many peasant proprietors each making their own little bargains individually could not be nearly so advantageous as some system of co-operative bargaining. In conclusion, he remarked that all he had been able to contribute was a leaf from his experience in another country as a practical administrator who had to find for the peasant proprietor a way out of his difficulties, but his belief was that it was more difficult to get into the general mind the idea of co-operative marketing than the idea of co-operative banking.

Mr. Henry William Wolff congratulated the author upon the paper he had read, which was exceedingly interesting. Of course, Mr. Rothfeld had spoken a good deal of his own Presidency, where he and his predecessor, Mr. Ewbank, had done exceedingly good service. Bombay was not at first the very best province, but now it stood in the front rank. He was very glad to hear from the Secretary of State that something had been done in the West Indies, and he had little doubt that co-operative marketing which had been established in Jamaica would be established in India also. It was thirty years since he took upon himself to direct an appeal to the then Secretary of State for India (Lord Geprge Hamilton) urging the passing of some Act which would legalise co-operation in that country. There were various schemes at that time for some form of insurance against damage and for co-operative effort, but Sir Frederick Nicholson's masterly report had not been published. The late Lord Wenlock told him that he had been very much interested in co-operation, having learned what was being done in other countries, in Italy particularly, and he had sent Sir Frederick Nicholson there to study the conditions. The speaker's appeal to the Secretary of State fell upon fruitful ground. He had particularly urged from the beginning, as Lord Curzon had stated in sanctioning the Act of 1901, that the co-operation necessitated in India should be based upon self-help, not upon State-help, and not upon officialism. It should be the people's own affair, governed eventually by themselves, and dependent virtually upon their own resources, with the Government aid in money at the start, cut down to a minimum. That principle was readily adopted by the authorities in India, and they stuck to it right through, finding, as unimpeachable observers had stated, that it answered admirably. The author had referred to complaints which were made that there was not more co-operation in India, and that the whole ground had not been covered. But such a complete transformation was quite impossible under the circumstances. After all, India stood foremost in respect of rapid development and the attainment of good results; in Germany, Italy, and everywhere else, excepting Russia, which had the advantage of artels, progress had been very much slower. He believed that the Indian Government had steered a right course; it had had particularly able registrars, who had shown not only zeal in this matter, but also quite wonderful command of resources. New applications had been started in various provinces which had given exceedingly good results and which really deserved emulation. The Government of Burma was now considering the question of re-organising mortgage credit. At times, of course, there had been a little impatience; summary powers and Government support had been asked for, but these had been denied, and now they saw a co-operative banking movement established with only a very small proportion of Government assistance remaining. One result of co-operation which the author had not mentioned was its most remarkable educative value. This had been seen in the way that Indians managed their self-governing councils, and in the ambition for the spread of education generally. The movement had a stimulating effect also in causing co-operators to turn to other forms of co-operation, especially in agriculture. The agricultural authorities had become the allies of co-operation, and this worked to the best advantage of the country. Lately people interested in co-operation in India had taken to travelling abroad and seeing things in other lands. He thought the time had come when India ought to be content with its own system, for that system had its own distinctive features suited to the country. He thought that the co-operative movement in India had a great future before it. Some of the people had been bitten with the idea of having co-operative stores, and had been to Manchester and Glasgow and seen the movement there. Given the well-paid artisan in India as in this country, the co-operative movement could be made as flourishing there as here, and he looked forward to the time, if the movement proceeded on the lines on which it had begun, when what a native registrar wrote about a decade ago, would be seen to be the actual fact: "Co-operation is the best gift India has yet received from its rulers."

Mr. Alan F. Fremantle, I.C.S. (United Provinces) said that as regards some complimentary remarks made that evening by the father of co-operative trade societies, the credit belonged to his brother (Mr. Selwyn Howe Fremantle). His own work, compared with his brother's in India, was very unimportant, but in his position as an Indian civil servant, as district officer, he had been Chairman of three district banks at different times. The most interesting paper had been almost above his head, because he came from such an exceedingly backward province compared with the author's, although it was one deserving of consideration, because the largest province of India, and, as many thought, the primary province. He would like to point out some of the characteristics of co-operative banking in the United Provinces so far as he had learned them. Co-operative banking was almost entirely confined to agricultural societies. The principle on which it started was rather the principle which the Secretary of State and Mr. Wolff had brought forward than the principle expounded by the author. The object was to rescue the ordinary peasant or agriculturist from the hands of the money-lender. The money-lender had to meet a great many difficulties, he had his bad debts and his legal expenses, or if he did not have legal expenses he had to keep one or two hefty retainers to go round and beat his debtors. The underlying idea, of course, was that the credit of a dozen people was better than the credit of one person. A dozen people could get a loan of 50 rupees each, as a result of co-operative credit, at a lower rate of interest than if they took out such a loan individually. The village society probably had anything between a dozen and two dozen members. They all lived in the same village, and the problem was to get them capital. For that purpose an urban or a district bank was brought in. The bank was merely an organisation for financing the village societies; it did not have pass-books or cheque books. These village societies were scattered about the district; in a given district there might be six or seven circles, just as, in the county of Kent, for instance, a circle might be drawn around Canterbury, another around Sevenoaks, another around Tonbridge, and so on. Each of these "circles" had a secretary, who was the paid official of a headquarters bank, and received about 20 rupees a month. The expenses of the village societies were almost nil; the only cost was the expenses of two or three of the managing committee of the societies in going to headquarters three or four times a year to fetch money. The village societies, he thought, paid 12 per cent. to the headquarters financing bank for their loans, while 15 per cent. was the rate at which members of the village societies borrowed from the societies. The individual members had to buy shares in their village societies; the shares were 20 rupees, and were paid for by half-yearly instalments of one rupee. At the end of ten years, therefore, they were paid off. It might be said that the 15 per cent. was not a particularly low rate of interest, because 2 or 3 per cent. had been mentioned, but it had been found to work out quite satisfactorily and the borrowers were content. The difficulty with which they had been faced in the United Provinces was the temptation which this village finance offered to the politician. There had been a tremendous effort made in the United Provinces to get hold of the organisation of the banks. When a political clique got hold of a bank and began to appoint secretaries and to establish the whole organisation of the village societies, of course, proper co-operative banking went into the background, because a man was chosen as secretary, not for his qualifications in that office, but for his skill in spreading political views. At one place he himself had an amusing experience as chairman of a meeting at which the directors of the bank were to be appointed; a large number of gentlemen, in their eagerness to elect certain people as directors, climbed over the railings and claimed the right to vote, although they had no shares, and he had the greatest difficulty in getting the proper selection; in the end he had to give it up, and call another meeting, with a very elaborate system of tickets and examination by the police before anybody was allowed to come in. Only shareholders were then allowed to vote, and the proper persons were elected. If one were to permit the organisation of a district bank to get into the hands of the politicians it would be unfair to the original persons who financed these banks, because they never intended their money to be so used. That was a great difficulty in banking in his part of India. One would, of course, like to de-officialise everything as much as possible, but one was up against the clever lawyer-politician who did not care what became of the money, and there was a great possibility of the money being misused and misapplied, and of banking in that particular district going to utter ruin.

Mr. S. Saklatvala congratulated the author on bringing to the notice of the British public what appeared to be the most important factor in the development of the backward life of India. Mr. Rothfeld had been quite frank with regard to statistics and the fact that they were not up-to-date. Since the statistics for the Bombay Presidency were finished large banking establishments had been started in Bombay. Mr. Wolff had pointed out that the banks must not be made into State concerns. But State money in a country like India was also the people's money. While there was a sort of understanding, if not a rule, that the Government money should be held in such and such a proportion in the Presidency banks, or even in the exchange banks, the same principle might be applied with even greater justification to the co-operative banks, in which the Government might hold some of its surplus revenue. It was unreasonable to expect the people who needed the co-operative system most to build up the co-operative bank unaided. With regard to paper money, was it not a fact that paper money could not be successfully introduced into a country where the spending coin of the agricultural village was still the *pie*, or one-third of a farthing? That was the coin with which the people had to do their marketing and shopping. He believed the uplift of the economic condition was closely allied with the problem of substituting coin money for paper money.

Lord Olivier, with regard to a remark made by Mr. Fremantle as to rates of interest, said that in Jamaica money was lent to the village societies at 6 per cent., and they charged 7 per cent. to the borrowers. He did not know why the rates were so much higher in India.

Mr. J. M. Mitra, Registrar of Co-operative Societies, Bengal, said that his experience in Bengal showed that if money was lent to people at a very low rate of interest, they tended to borrow more than they could pay. It was found that if the co-operative societies borrowed money and lent it at a cheap rate it would actually deter the progress of co-operative banking. The Government of India, from the inception of the co-operative movement, limited its assistance to a very small sum, out of which it lent money to co-operative societies. One aspect of the banking movement had not been touched upon—namely, the immense possibilities of the movement in bringing the financing of trade and commerce into direct touch with agriculture. It was only through the co-operative movement that the financing of trade and commerce had been brought face to face with the financing of agriculture. The exchange and imperial banks had so far stood apart from the financing of agriculture; now they found that by lending their surplus money in times of stress, they could get the surplus funds of agriculture in times of abundance. This aspect of the progress of co-operative banking demanded some attention. It was as a part of this progress that the financing of trade and commerce had been linked with the financing of agriculture.

Mr. Rothfeld said that he was gratified to find that his paper had raised so much discussion, though the absence of any acute criticism made it difficult for him to reply. Mr. Fremantle, in his speech, unwittingly raised a point which was of the greatest importance to the development of co-operation in India, and as he (the speaker) had the honour of including in his audience the Secretary of State for India he might be allowed to emphasise this point. Mr. Fremantle had spoken of his own province as a backward one, and had said that in consequence much of the paper was above his head. The inherent difficulty was one which he had felt very strongly. What was the actual position in India? In that land there had been grouped in one federation or government countries as divergent as Serbia and Bulgaria were from England and France. They were governed by a body of men who spent six months of the year in the equivalent of Geneva and the other six months in the equivalent of Rome, which was once the capital of Europe. The officials who were occupied with conditions so diverse were recruited on a system, such as if only officials recruited in the Argentine Republic were appointed to the central European Government after two or three years spent in France or Spain, and as if these officials were looking forward to those appointments which would make it possible for them, as he had already said, to enjoy the climate of Geneva in the summer and the society of Rome in the winter. The legislation of Bombay, for example, was tested by a criterion applicable to the Punjab and Assam, which was ludicrous in the case of an industrial province like Bombay. The same thing applied to every form of banking and trade. There was failure to realise the actual conditions under which others worked and laboured. It was this which was now leading India to the breaking point, the Reform Scheme having been rendered so largely nugatory and impotent. The liberty and power intended to be conferred by the Reform Scheme had been restricted and largely taken away, and it was this which was causing grave and serious discontent and was fraught with danger for the future. To leave aside the political question, on the administrative side in connexion with a thing like co-operative banking much harm was done by grouping together every province, making them submit statements in the same form, and generally dealing with the matter in a fashion which was quite intolerable.

In answer to the questions which had been asked, he would like to say that real progress had been made in co-operative marketing in Bombay Presidency, but it was only about one-thirtieth of what it ought to be to influence the market. As for the co-operative credit societies, he had forgotten what was the total number of these in India, but in the Bombay Presidency it was 3,200, the members numbering 300,000, and a working capital amounting to 5½ crores. With regard to the co-operative banks serving as public treasuries in districts not already served by the Presidency Bank, this principle had been more or less vaguely accepted by the Government and also by the co-operative movement, but the difficulty was at present that no co-operative bank in Bombay was so far in a position to volunteer and guarantee proper performance of service. He had no doubt that one of the banks would very shortly do so, under the stimulus of encouragement which was being given. The quarterly financial statements submitted by the banks were checked, and the registrar had power of cancellation under the Act—a power which obviously could hardly be used against a district bank, but the mere existence of which served to some extent as a check. In Bombay the supervision was really exercised for them and more satisfactorily by the Provincial Bank, whose financial interests were involved. With regard to official control, he agreed that where an official was held responsible for a thing he could not allow anyone else to mismanage it. He could not, however, agree with the general implication which most officials deduce from this, namely, that he should remain responsible with and behind the non-officials. Where it was possible to let non-officials do something, the official ceased to be responsible. The moment there was a non-official body it was authorised to sink or swim. The official might have powers to control and check, which he should exercise from outside, but the idea of the collector being the president of a co-operative bank was wholly repugnant. This seemed to be distinctly inconsistent with what was intended by co-operation. With regard to his definition of money, as given in the paper, he held that by money was meant a right to exact certain services or actions from other people, or a promise to perform such services. Mr. Wolff had urged that they should not be in too much of a hurry. The speaker agreed, but the point about India was that they had no time to waste. The country had been left very far behind the needs of the modern industrial capitalised world, and if they did not hurry up as far as they could with safety it was going to be left behind hopelessly. He urged, what appeared to him to be the primary necessity of the case, to make up the tremendous leeway in education, which was nowhere felt more than in the co-operative movement. The co-operators at a recent Council election moved forward to the hustings with banners flying and bands playing. He hoped that India would move forward to education in the same spirit.

Sir Robert W. Carlyle, K.C.S.I., C.I.E., moved a vote of thanks to Mr. Rothfeld for his paper and to Lord Lamington for presiding. The co-operative movement was one in which he took the very greatest interest from its infancy and he was in close touch with it for eight years. He thought there was no movement in India which was more important and could do more to promote self-Government and co-operation in the agricultural and working classes, and the

author had shown its importance from a banking point of view in the Government of India.

The motion was carried unanimously, and the meeting terminated.

LA VIE INDUSTRIELLE EN FRANCE.

◆

Les Usines sidérurgiques de Caen.

La Société des Hauts-Fourneaux de Caen avait été fondée en 1910 par les industriels allemands A. & F. Thyssen, avec le concours de la Société Cail. Peu après, à la suite d'une intervention du gouvernement, la participation allemande fut réduite des ¾ à ⅓ seulement, lorsque la société porta son capital à 30 millions de francs. En 1914, les dépenses d'établissement s'élevaient déjà à 40 millions.

Pendant la guerre, les conventions passées avec les industriels allemands furent annulées, et la "Société Normande de Métallurgie" fut fondée par M.M. Schneider et Cie, les Forges et Aciéries de la Marine et d'Homécourt et la Société de Pont-à-Mousson. La nouvelle Société poursuivit les travaux de construction, mais le premier haut-fourneau ne fut mis en service qu'en 1917.

L'achèvement de l'usine et de ses installations accessoires fut assez lent, et la marche de l'usine fut entravée par la crise industrielle de 1921. En 1922, cependant, la reprise des affaires permit le développement de la production, et les établissements métallurgiques de Caen ont maintenant un fonctionnement normal, bien que toutes le installations prévues soient loin d'avoir été exécutées jusqu'ici.

L'usine a été édifiée sur un terrain de 400 hectares (1,000 acres), à 4 kilomètres de Caen. La Société a pu installer un port particulier de 8 mètres de profondeur, pour l'importation du charbon et l'exportation du minerai et des produits fabriqués.

Les principales installations sont les suivantes: batteries de fours à coke et usine pour le traitement des sous-produits; hauts-fourneaux; aciéries Thomas et Martin; laminoirs; fonderies et ateliers de mécanique; centrale électrique; services annexes (chemin de fer, port, etc. . .).

Les produits fabriqués sont les produits métallurgiques: rails, profilés, etc..; les sous-produits: sulfate d'ammoniaque, benzol, huiles; enfin, les phosphates et le laitier granulé.

La disposition générale de l'usine a été étudiée très judicieusement, pour assurer la circulation méthodique des matières premières et des produits finis.

On a prévu 6 hauts-fourneaux, mais 2 seulement sont construits et en service; ils donnent chacun 400 tonnes de fonte et 200 tonnes de laitier par 24 heures.

Chaque haut-fourneau a 27 m 30 (89′ 5″) de hauteur et un diamètre au ventre de 7 m 10 (23′ 3″). Le minerai employé provient de la région; il contient de 42 à 54% de fer, 8 à 15% de silice, 0.6 à 0.7% de phosphore et 5% d'alumine.

Les fours à coke comportent 6 batteries de 42 fours d'une contenance unitaire de 10 tonnes. Ils sont à régénération de chaleur et à récupération des sous-produits. La production de coke est d'environ 250 tonnes par 24 heures.

Les aciéries sont logées dans un bâtiment en béton armé de 273 mètres de longueur (896 feet). L'aciérie Thomas est la plus importante, l'usine devant traiter surtout de la fonte phosphoreuse au convertisseur; elle comprend 3 cornues et un mélangeur de 700 tonnes. L'aciérie Martin contient 5 fours de 30 à 35 tonnes.

Les laminoirs sont dans des bâtiments de 450 mètres (1,476 feet) de longueur, disposés parallèlement à l'aciérie. Jusqu'ici, deux trains seulement sont en service: un duo réversible de 0 m 90 (3 feet) à 4 cages, et un semi-continu pour la fabrication des fers marchands.

On doit prochainement compléter cette installation par des trains moyens et une tôlerie moyenne.

Aux environs de l'usine, une cité ouvrière a été construite pour le personnel, et elle offre déjà 800 logements.

Lorsque les hauts-fourneaux prévus et les nouveaux laminoirs seront tous construits, les usines de Caen constitueront sans doute le plus grand établissement métallurgique de France.

Reservoirs souterrains pour Fuel-Oil des Etablissements Arbel & Pellerin.

La Société des Etablissements Arbel (Forges de Douai) et l'Entreprise Louis Pellerin, de Paris, se sont associées pour la construction de réservoirs à liquides combustibles, tels que: pétrole, essence, alcool, mazout, gas-oil, fuel-oil, etc. Ces réservoirs sont complètement enterrés, et au besoin rendus absolument invisibles par une couche de terre recouverte de broussailles, qui les dissimule aux avions.

Ce type de réservoir est constitué par une enceinte indéformable, en béton armé ou non, construite pour résister à tous les efforts de poussée, et munie d'un revêtement intérieur formé de plaques embouties en tôle, soudées entre elles par leurs bords, et assurant leur étanchéité. La soudure de ces parois verticales est exécutée à la fois à l'intérieur et à l'extérieur de chaque panneau en tôle, suivant des lignes continues, donnant une sécurité complète pour l'étanchéité.

Les parois verticales en béton sont construites au fur et à mesure du montage des rangées de tôles, les parois de celles-ci servant de coffrage.

Les tôles, adhérant parfaitement au béton, ne peuvent se déplacer, et le réservoir ne comporte aucun risque de fuite.

Les éléments de tôles embouties sont interchangeables, ce qui simplifie la construction, et permet d'approvisionner des panneaux de rechange, pour le cas où une tôle viendrait à crever.

LE BATEAU CABLIER "CYRUS-FIELD," CONSTRUIT EN FRANCE POUR LA WESTERN UNION TELEGRAPH CO.

La dépréciation du franc par rapport à la livre sterling a eu pour conséquence de permettre à des industriels français de concurrencer des firmes britanniques dans des spécialités où elles n'avaient guère de rivales jusqu'ici. Plusieurs ateliers des environs de Paris usinent des pièces mécaniques destinées, indirectement, à l'Amirauté. Il y a quelques années, les grandes compagnies de navigation faisaient construire des navires par les chantiers britanniques; maintenant la Western Union Telegraph Co. a commandé à la Société des Chantiers et Ateliers de Saint-Nazaire (Penhoët), un navire destiné à la pose des câbles, le "Cyrus-Field."

Ce navire, qui a été lancé le 21 février, a un déplacement de 2,155 tonnes, et un tonnage de 1,070 tonneaux. Sa longueur est de 64 m 30 (211 feet), sa largeur de 10 m 36 (34 feet) et son tirant d'eau de 4 m 87 (16 feet). Ses machines ont une puissance de 1,200 chevaux et la vitesse doit être de 11,5 nœuds.

Il est à noter que la France possédait depuis de longues années plusieurs bateaux câbliers qui ont permis la pose de grands câbles transatlantiques. Le navire "François-Arago," par exemple, a posé l'un des derniers grands câbles, celui reliant directement la France au Sénégal, de Brest à Dakar.

LES ESSAIS DE CULTURE DU COTON DANS LE SOUDAN FRANCAIS.

La diminution constante de la production cotonnière des Etats-Unis, et, par suite, de leurs exportations en coton brut, est une grave menace pour l'industrie textile européenne. Aussi, chaque pays industriel s'est mis en devoir de cultiver le coton en grand sur ses propres territoires. L'Angleterre dispose, à cet effet, des Indes et de l'Egypte, qui ont produit en 1923, respectivement 1,040,000 et 325,000 tonnes, sur un total de 4,720,000 (dont 2,600,000 pour les Etats-Unis).

On peut cultiver le cotonnier en Indo-Chine, dans les colonies françaises de la Polynésie, et en Afrique Occidentale, mais la production indochinoise sera absorbée par le marché chinois; celle des îles, du Pacifique ne sera jamais très abondante; il reste donc surtout l'Afrique occidentale, à laquelle la proximité de la métropole procure déjà un grand avantage. De plus, le cotonnier y est cultivé depuis longtemps par les indigènes pour satisfaire aux besoins locaux; sa culture paraît pouvoir s'y développer sur des espaces immenses et dans des conditions climatériques favorables.

L'Association cotonnière coloniale a, depuis un certain nombre d'années, apporté un appui très précieux aux essais tentés dans ce but, et l'industrie française a déjà, en 1923, reçu 800 tonnes de coton de l'Afrique occidentale. La région qui se prête le mieux à sa culture comprend tout le haut Sénégal et le haut Niger, jusqu'à Timbouctou. Les produits de cette région trouvent d'ailleurs une porte de sortie facile par les voies fluviales et par les deux voies ferrées qui la relient aux ports de Dakar et de Konakry.

Un vaste projet d'irrigation par les eaux du Niger a été établi, mais il serait très coûteux et de réalisation très longue. Certains ingénieurs agronomes préconisent, comme plus rapidement efficace et plus économique, la "culture sèche" du cotonnier, aidée au besoin de simples arrosages et perfectionnée par la sélection des variétés indigènes, ainsi que par leur hybridation avec les variétés américaines les plus appropriées.

NOTES ON BOOKS.

BURMA, from the Earliest Times to the Present Day. By Sir J. G. Scott, K.C.I.E. London: T. Fisher Unwin, Ltd. 21s. net.

As Phayre's *History of Burma* is now scarce, and as much has happened since the annexation of Upper Burma, there is room for a complete history which would start from the old Kingly Chronicles and end with a description of Burma's essay towards reponsible Government on Western lines. No one could be more qualified than Sir George Scott to prepare such a volume; and his name is a guarantee of erudition, sympathy and comprehensive treatment. There is in his style a vein of caustic description, a criticism which the author has forestalled by admitting in his preface the possibility of a charge of flippancy. The charge is met by the statement that it is not un-Burmese.

For the Western reader real interest in Burma's story is excited when the accounts of the early European travellers in the 14th and 15th centuries are given. The descriptions of the relations with China and of the employment of Portugese mercenaries are of great interest; and later the experiences of the various British Envoys, which are given with circumstantial detail—those of Captain Symes in 1795, Captain Cox in 1796, and of Captain Canning in 1809—are illuminating as illustrative of the race pride of the Burmese.

We learn with interest that the novelist, Captain Marryatt, took part in the first Burmese War; and that King Thibaw, the subject of the Third War, survived till quite recently when he died a State prisoner in a fortress in the Bombay Presidency during the Great War. Each of the Wars showed progressive increase in knowledge, efficiency and success on the part of the British.

Of the Burmese we are told that he is incorrigibly lazy with no desire to heap up money; that he is indolent by nature and intolerant of discipline; and that one of the greatest tasks of the British Government has been to protect him against himself. The people of Burma are the most literate in the Indian Empire; and those who in recent years have promoted religious and racial antagonism are, in Sir George's opinion, not genuine Burmans.

Sir Charles Bright, F.R.S.E., M.Inst.C.E., M.I.E.E. ..	1	1	0
Percy Hamilton Mackay, Esq.	1	1	0
Miss Emma S. Boyd	1	0	0
Captain William V. G. Fuge ..	1	0	0
Total	£42,931	15	5

The above list includes all subscriptions received up to April 26th. Further lists will be published in the *Journal* from time to time.

Fellows of the Society are reminded that the amount aimed at by the Council is £50,000, which will cover the cost of renovating and decorating the House.

*A complete list of Subscriptions received up to January 31st, was published in the *Journal* of February 15th, 1924.

NOTICES.

NEXT WEEK.

MONDAY, MAY 5th, at 8 p.m. (Extra Meeting.) T. THORNE BAKER, "Photography in Industry, Science and Medicine." SIR HERBERT JACKSON, K.B.E., F.R.S., will preside.

WEDNESDAY, MAY 7TH, at 8 p.m. (Ordinary Meeting.) J. ROBINSON, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation." ADMIRAL OF THE FLEET SIR HENRY JACKSON, G.C.B., K.C.V.O., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

FELLOWSHIP OF THE BRITISH EMPIRE EXHIBITION SCHOLARSHIPS.

LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, LORD LEIGH, Fellow of the Society, and LT.-COLONEL SIR HENRY MCMAHON, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I., a Vice-President of the Society, have been appointed trustees of the sums to be paid on behalf of the scholarships to be given by the Fellowship of the British Empire Exhibition.

VISIT TO THE GUILDHALL.

On behalf of the Fellows of the Society and their ladies, the Council have gratefully accepted an invitation from Mr. H. G. Downer, LL.B., a member of the Common Council, to inspect the Guildhall, including the Art Gallery of the Corporation of London, on Thursday, May 8th, at 2.30 p.m.

Sir Alfred George Temple, F.S.A., will act as escort in the Art Gallery, and Mr. Deputy Alderton, C.C., in the Council Chamber, Crypt and other places of interest in the Guildhall.

Fellows desirous of availing themselves of the invitation should inform the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2, on or before May 6th, mentioning the number of their party. No tickets are necessary.

Those attending are requested to assemble at the main entrance to the Guildhall in King Street, Cheapside, at 2.30 p.m.

PROCEEDINGS OF THE SOCIETY.

SIXTEENTH ORDINARY MEETING.

WEDNESDAY, 26TH MARCH, 1924.

ERNEST WILLIAM MACBRIDE, ESQ., M.A., D.SC., LL.D., F.R.S., Professor of Zoology, Imperial College of Science and Technology, in the Chair.

The paper read was :—

THE FISHING INDUSTRY AND ITS BY-PRODUCTS.

By NEAL GREEN.

To compress a description of the Fishing Industry within a short paper is a most difficult task. There are so many equally important questions arising that it is impossible to discuss all, so you will perhaps excuse me if my narrative is somewhat cursory and rambling.

The British Fishing Industry is cut into two quite different parts. The Herring fishery has a long and varied history, and for centuries has been an important article of commerce; most probably taking a much larger share as an article of food for Eastern Europe than at present, so much so, that often its importance was the cause of international strife. With regard to White fishing (which includes almost all kinds of fish of white flesh, and generally trawled or caught by line), its history as a thriving industry is practically contained in the last half century. Herrings generally were salted and preserved to keep good indefinitely. White fish are not improved by this method, consequently it was only by the advent of the Railway and the possibility of a quick delivery to inland towns that trawl fishing on a truly commercial scale was possible. Quick transit and the consequent arrival of the fish in a state of freshness created a larger demand, which the introduction of the steam trawler and the manufacture of artificial ice still further improved, and this made possible the prosecution of the fishery on a very large scale. So successful was the trawl method of capture that supplies soon overtook the demand, and it was a common and truly wasteful method forty years ago to throw overboard most of the catch and bring to port only the selected kinds of better class fish, for which a demand would not be uncertain. This senseless method of carrying on the fishery was the beginning of the exhaustion of the North Sea banks. The rejectamenta thrown overboard fouled the grounds, and of course, was no advantage. Then, as the larger fish became scarcer, the smaller varieties were caught and nursery banks were interfered with, until at the outbreak of the Great War a period was reached when most of the cheaper kinds of fish consumed in this country were caught as far away as the Faroe, Iceland and North Russian grounds.

It was thought that the War years of enforced cessation of fishing in the North Sea would greatly improve conditions, but although fish were very much more plentiful for a year or so afterwards, the signs of a depleted stock of mature fish soon began again to appear, until to-day there seems to be less of these fish in the North Sea than at any time in its past history. Even the Faroe and Iceland banks are beginning to show signs of being overworked, and whereas the North Russian grounds on their discovery were packed with thin starved fish, they now produce denizens much better fed and in better condition, proving that the trawler is already thinning their ranks and thus giving more opportunities for the surviving fish to find food.

The greatest fisheries are those nearest to large populations which, by their demand for fish food, cause the neighbouring seas to be worked most extensively. In early European history the Mediterannean provided the best supply and it was this inland sea which furnished the food, the trade, and the easiest means of travel and intercourse in those days and thus promoted the earliest European civilisations. The advantages for fisheries, however, are much greater in the North Sea, as there is a constant current from the Atlantic conveying plankton, or water suitable for the growth of plankton —a word invented by Hensen to denote the enormous mass of minute species of fish and eggs, which are carried among the waters as a sort of living emulsion forming the nourishment, either directly or indirectly, for all kinds of fish. The North Sea has other advantages; it is shallow, it is fertilised by the inflow of rivers as well as ocean current; it is temperate, and it is surrounded by a coastline occupied by enormous populations, which thereby provide a ready market for its produce. Little wonder then that it should be the most valuable fishing ground exploited. It is no mere accident that Nature providentially provides the most important fishing sea so close to our teeming population. It is the population which has made the fishery of such value. How do we know that the trawler or the line fishing boat can cause harm or diminish the ranks of marine life if worked wisely? Left alone, fish eat one another, the advent of man harrowing the sea bed with his trawl may do much more good than harm if he avoids immature fish or the beds on which they predominate. Taking the sea area of the world as a whole, it is the wolves of the sea which take the greatest toll of sea life, and to maintain the best varieties of fish man will have to reduce, if not exterminate, the useless sea monsters inimical to their well being.

There are other fishing grounds just as fertile, such as those off Newfoundland, Nova Scotia, or the western coast of Canada, but hitherto distance from the consuming population has always been a severe handicap, a disadvantage, however, that will be reduced as transport facilities improve and their neighbouring populations increase.

From the British ports the trawlers are continually going further afield, and to-day the North Sea probably supplies only about half the quantity of fish brought into this country. The banks off the Faroe Isles and Iceland are now trawled thoroughly and the North Russian coast is providing a much better quality of fish than formerly. Other banks in the North Atlantic are those contiguous to the Lofoton Isles, where the Norwegians obtain most of their cod fishery supplies; the Barentz Sea which has not yet been fully explored and may yield good supplies as the other banks fail. Also, on the Canadian side there may be good opportunities in Davis Strait and Baffin Bay, and the seas between Greenland and Iceland may prove lucrative, for to the north west of Iceland there is a submerged reef forming a shallow sea between Iceland and Greenland. There are favourable indications that we have by no means fully exploited these northern seas, for the European Stream which invades these waters most likely carries a good supply of oceanic food to maintain countless numbers of good edible fish. It is, however, in the North Sea that we find the best variety of the more highly prized fish. The turbot, sole, brill are not found in the far north, and of other kinds the North Sea provides the best qualities: this most likely is mainly because they can be landed in the freshest condition, but not altogether for this reason. There is no doubt but that as the banks vary in fertility, depth and formation, they may effect the flavour of the fish themselves. Thus plaice and soles may prefer certain banks and the astute fisherman knows where he can find them in their best condition and numbers, and when is the best time to go to these reefs or pits for his catch. In frosty weather he knows that soles are likely to creep into the pits to the south of the Dogger Bank for warmth, and for this reason often in cold weather you will find the London shops well provided with soles. Again he has to be acquainted with the migration of fish, to know that if the herring fishery is in full swing there are likely to be large shoals of codfish and haddock following the herring and consuming it and its spawn, for as the great annual herring migration takes place, it not only provides a large human population with work, it also offers itself an easy prey to foes of its own world. From a commercial point of view the herring is the most important migrating fish. Its annual pilgrimage down the East Coast of Britain has long been a phenomenon. The fishing first centres at Lerwick and Stornoway, and the drifters follow the shoals down, working successively from Wick, Peterhead, Frazerburgh, Shields, Scarborough, Grimsby, Yarmouth and Lowestoft. This annual movement of the shoals is the opportunity for a great harvest to the herring fisherman, yet little is known definitely of what really happens to the fish. They appear, and after the migration disappear, having spawned and littered the North Sea with their eggs, thereby providing a welcome feast to almost every kind of trawl fish. Of the other varieties, although there are movements, there are no definite journeys on a large scale.

It is a mistake to imagine that the North Sea fish migrate to the depths of the Atlantic. The submerged continental plateau of the North Sea is peculiarly suitable to the life of shallow-water fish, and they never leave it. A deep-sea fish, with few exceptions, such as the eel, cannot live in shallow waters, and a shallow-water fish, such as is found in the North Sea, cannot live in the depths of the Atlantic.

The softness of the flesh of the hake is owing to its habitat being the deep water of the west coast. Living in the deeps it has to bear a very much greater water pressure, and it is when this pressure is released that the flesh becomes soft. Sometimes hake are caught in the North Sea in shallower water and the firmer flesh is very noticeable.

Most of the trawl fish is now landed in the few large ports where convenient railheads serve to centralise the industry. Grimsby and Hull owe their position to the close proximity of the Dogger Bank and to the South Yorkshire collieries, which supply good steam coal within reasonable railway distance. Aberdeen mainly serves Scotland. Fleetwood has a ready market in Lancashire, whilst Swansea and Milford Haven help to supply South Wales.

Let me give you a fairly accurate description of a fishing port as seen by a visitor. This is what Monsieur Roy, a Frenchman, says of Grimsby :—

> "It is a curious spectacle, the sight of the fleet of trawlers ascending the Humber from a period of two hours before flood tide, at which time the tidal gates are opened. As far as one can see the heavy, troubled waters are obscured by the smoking funnels of the boats as they hasten in, for the place which they will occupy along the pontoon is not without importance, as the sale begins at the northern extremity of the shed. Between the jetties, which are, perhaps, too close together, there is a hustling, a veritable scrimmage, of hurrying vessels, which are continually thrown against one another by colliding bows and beams; but there is never a serious collision, and it seems a miracle that there is not. The docks gradually become busy; the first arrivals tie up to the best places in the first basin; bows on to the quay, they arrange themselves in close-packed ranks. When the first dock is filled, the newcomers, in order to reach the second, have to make a sudden turn at the apex of the triangle formed by the pontoons; but they scarcely slacken speed, lest a less cautious skipper should pass his rivals. Faster and faster they arrive, urged on by the tide; taking the corner at a lively speed, bumping vigorously on the solid wooden guards of the quay, and often heeling over a considerable angle; but no harm is done; if they collide they recoil from the shock, and the great thing is to be moored to the quay in good time. Unloading commences at once; the baskets are hoisted from the hold loaded with fish; there is a continual going and coming on the gangways thrown between the bows of the vessels and the quay. The codfish, all dead, with glassy eyes, are stretched out in lots; enormous halibut spread their white bellies, some, still shaken by convulsive shudderings, opening and shutting their huge mouths. The smaller species—whiting, plaice, haddocks, etc., are arranged in wooden boxes, which are set in rows along the pavement, still impregnated with the smell of yesterday's catch, in spite of the washing it received last night. At eight o'clock the auction commences. At the northern extremity of the shed the official auctioneers bawl out the names of the fish they are offering for sale. The buyers are everywhere, stamping to and fro in their heavy boots among the slimy fish; each, as a lot is knocked down to him, replacing the seller's ticket by his own. Porters appear immediately and remove the fish as it is bought, trundling it along on barrows to the shed rented by the buyer within the market enclosure. Others have large smokehouses connected with the market. Thus the sale goes from end to end of the quays, and all the morning and afternoon an army of jostling labourers wash, scrub and pack the fish, and load it on the railway trucks. From time to time a locomotive whistles; a train is made up and pulls out of the market. Sometimes men armed with long sharp knives go by almost at a run, working at the closely packed rows of cod, plunging their knives into each fish, and snatching the livers from the slippery bodies.
>
> The fish has now been sent in all directions: 700, 800, often 1,200 tons of fish, occupying 200, 250, or 400 wagons. Meanwhile the trawlers, who will put to sea on the following morning, have lost no time; they have filled the holds of their vessels with ice, the bunkers with coal, seen to their spare stores, and replenished their stock of victuals. The Grimsby Ice Factories, the largest of the kind in the world, are situated near the quay of the fish dock. They make about 1,000 tons of ice every day. The trawlers are supplied with coal from hulks and lighters."

Refrigeration has been successfully used in bringing meat from the ends of the earth. For fish the present methods of cold storage have the effect of breaking down the gelatinous tissues and causing loss of flavour. Frozen fish is not liked. Here is scope for scientific investigation. I have found it an advantage in preserving fish to keep the temperature of the cold store as near zero as possible, so that actual freezing does not take place. In this way it is possible to keep the fish for short periods without deleterious effect. Of course, this method is not suitable for any length of time. In America, where inland distances are great, they dry the fish into white flakes which keep wholesome indefinitely,

We have now reached a period when the trawler works on a very small margin of profit; when, owing to the price of coal, higher wages, and the increased difficulty of finding sufficient quantities of fish, there is a tendency to raise the price to the consumer, which, if it continues, may soon bring us to a day when the demand may fall off and the industry pass its zenith. This leads us to many complex problems. We have gone from over-production, when the charges of profit levied by the fishermen, railway companies and shop-keepers were very small, to a period of under-production, when the consequent charges by those who have to live by the industry take a toll of a much greater percentage over what was taken ten years ago. We must remember that it costs twice as much to run trawlers to-day as it did then, the railway companies' charges are very much increased, and the shop-keeper, owing to a higher cost of living and increased rates and taxes, is looking for a higher percentage of profit. The costermonger, at one time a valuable agent in purveying cheap fish, seems to be disappearing, whether or not owing to the dole I cannot say. The consumer now expects his produce to be brought to his home by motor-van; the cost of which has to be added to the price, and these factors bring us to the oftentimes complaining public who eventually determine the prosperity of the industry. If people decide that fish is too dear in proportion to other foodstuffs, the demand will fall off and the fishery suffer. Fish is becoming a dearer food, but this is not caused by trusts or rings, for such a perishable commodity does not lend itself to trustification. Indeed, it might be an advantage to the industry and the public if "big business" gave the fishing industry more attention.

The only way to maintain our fishing population is to improve the methods of catching, transporting, preserving, and marketing the commodity, and to explore the possibilities of fishing banks still further afield.

The day will come soon when the depletion of mature fish in the North Sea will be a matter demanding thorough investigation by competent authorities. That depletion is taking place is abundantly proved. Thirty or forty years ago the greater part of the contents of the trawl were thrown back to rot. To-day nearly all is brought to port, and although there is still a certain amount of waste in distribution, it is not so bad as formerly. The yearly average of fish marketed in this country is about 1,200,000 tons, and of this there must be about 300,000 tons unused, for most of the heads, bones, fins, skins, etc., are thrown away by the consumer, yet of this much is now saved from the destructor.

Over one hundred thousand tons of fish and fish waste are now annually concentrated to a fine powder and fed to farm stock in this country. It is quite a simple matter to-day to convert fish into meat and this is being constantly done. This 100,000 tons is a clear gain over the waste of past years, and is a factor pointing to the possible salvation of the industry and a great source of profit to this country. Many kinds of fish are admittedly flavourless. To turn codfish into chicken is not a fanciful suggestion but a daily fact. The fish, after being converted to a dry meal containing a high proportion of albuminoids, is mixed with cereal foods and the balanced ration of albuminoids and carbo-hydrates is distinctly successful with our farmers. The intelligent stock breeder also takes advantage of the fish oils. The great nutritive value of cod-liver oil in the feeding of farm stock is shown by the National Institute for Dairy Research, who say "It is now regarded as definitely proved that the vitamin content of the milk can be raised considerably by the administration of small doses of cod liver oil to milk-yielding cows, and this without any undesirable effect on the quantity or quality of milk fat." It was only the shortage of foodstuffs occasioned by the War that overcame the English farmers' reluctance to revolutionise his feeding methods. So successful has become the introduction of fish as a cattle and poultry food, that to-day, if available, it would be easy to convert a million tons of fish into meal to the advantage of our farming industry. There is no doubt but that our egg production has been increased mainly by the use of fish-meal.

This brings a new factor into the industry, the factor of producing huge bulk supplies of fish for cattle foods and fertilisers—fish of no matter what kind, even whale, shark and dogfish—and thus taking a larger advantage of the produce of the sea. To do this the wasteful element is eliminated, climate and distance are not such greatly determining factors as formerly. It is generally admitted that the average person usually prefers fresh tasteful meat to the poorer kinds of flavourless fish, especially if the fish is not in the freshest condition. The advantages of following up fish concentration as a method of utilising the products of the sea are many. By these means it is possible to exploit fishing banks contiguous to other continents.

If the ships are completed with the necessary machinery, the concentration can be done at the fishery and the produce kept wholesome indefinitely.

Again, mankind catches the better kinds and does not seek the unpalatable species which in many cases are so voracious as to do much more damage to the fishing banks than man does himself. The porpoises of the Newfoundland banks consume hundreds of thousands of tons of good edible fish annually. A useful purpose for porpoises would soon be reflected in the multiplication of other fish. We have laws for the protection and preservation of seals, which must consume enormous amounts of valuable fish.

There is nothing so certain as that some day necessity will drive us to exploiting the open and far seas for food, and this country ought to face the possibilities before others get the advantages. The countries in the Northern Hemisphere take collectively about ninety million pounds' worth of fish annually out of the shallow seas. Wherever there is a seaboard nation with a big population, we have fisheries on a large scale. Great Britain, Canada, United States, Norway, France, Japan and China, all have large fisheries on their coasts. If this applies to the Northern Hemisphere, why do we not investigate the possibilities of the Southern Hemisphere where the water surface is so much greater? South of the Equator fishing banks are almost left alone, yet wherever there is water of 200 fathoms or less, there is a probability of a fishery. The fish may be of different kinds from those we are used to seeing on our tables, but for concentration methods it does not matter so long as they are edible. The coast fisheries of West and South Africa, South America, Australia, New Zealand, have not been pursued much because there is not a large population wanting the commodity. Yet if we can profitably fetch nitrates from Chile, frozen meat from Argentine, rabbits and apples from Australia, it should be possible to exploit the seas of the Southern World for the benefit of the excessive population of the Northern, and we may yet see huge fast-oil-driven liners ploughing through the Polar seas and laden with their produce.

Mr. James Johnstone in his book "Conditions of Life in the Sea," says:—

"From these figures it appears that the produce of a large uncultivated water area is less than that of a cultivated land area, whether we take the yield in fish or shellfish flesh, or the yield in dry substance as the basis of comparison. But a cultivated water area, such as a fresh water carp-pond, or a part of the sea near the shore treated so as to produce shellfish under the most favourable conditions, is capable of affording a rich "crop;" and if aquiculture were as intelligently studied and practised as agriculture, there can be little doubt that the sea would be more productive than the land. Thus Hensen estimated that the mass of plankton (ultimate organic substance) produced in the uncultivated Baltic was not far short of that produced upon cultivated land.

Let us attempt to compare the nature and density of life on a land surface in the temperate zone, with a sea surface of corresponding extent. If we were to explore a large tract of cultivated and forest land, in which crop-lands, meadows, woodland, streams and moorland occurred, we should find that everywhere vegetable life would be predominant, and that animal life would be comparatively sparsely distributed. Overhead in our meadow land and in the cultivated parts would be a few birds and insects, while in the soil and on the vegetation there would occur insects, worms, and here and there rodents like mice and rabbits. In the woodland animal life would be more abundant; insects would be present everywhere, and birds would be more numerous than in open country, yet birds would not be resident in every tree. Small mammals, though more numerous than in meadow land, would not be very evident. Perhaps animal life would be most abundant in the streams and lakes, but even here fishes, water insects and the aquatic mammals would not be very abundant. But everywhere vegetation would be comparatively luxuriant.

Suppose now that the waters of the North Sea were suddenly to disappear, and that the whole mass of life contained in them were suddenly to be precipitated to the sea bottom. What kind of picture would then be presented? We should see a vast, almost level plain literally carpeted with animal life. Everywhere there would be a glittering mass of fish scales, for we should see not only the fishes which live normally at the sea bottom, but also those which lived pelagically, like herring and mackerel. Hordes of invertebrates, crabs, starfishes, molluscs, etc., would be mingled with the fishes. The mud and sand would also yield their quota of living things, and these would be much more numerous than the few worms and insects contained in the land soil. Every square inch of the bottom would be heaped up with animal life, and the whole would be partially smothered by the plankton precipitated from the water. Vegetation, as it appears on the land, would be very scarce, for the sea-weeds would be confined to the coastal margin; and we should hardly recognise the plankton as of vegetable nature. The irresistible impression would be that the sea was very much richer in life than the land.

Such an impression would be an accurate one.

For production of organic substance upon the land is restricted to the surface of the soil, and to a very thin layer of the latter; while in a shallow sea, like the North Sea, production by plants is carried on throughout a stratum of water, the average thickness of which is not less than 200 feet. Though sea-weeds only exist along the shore, and at the sea bottom near the latter, yet the vegetable plankton exists practically everywhere, and at every level of the water filling up the North Sea basin. Then we find vast tracts of dry land, which are either utterly sterile, or are productive to a very slight degree. Such are desert lands; the higher rocky parts of mountainous country; the enormous tracts of land covered transitorily or permanently by snow and ice; and the relatively unproductive moorlands. And even of the productive land surface only a very small part is under cultivation. But everywhere in the sea, even under the ice and in hot and cold areas, we find abundant life. No part is sterile, and the variations in productivity are, when compared with those on the land, of little account. If we take equal average areas of land and sea, we will find that the yield of the latter is greater than that of the former. Even the comparatively poor yield in fish per acre of the North Sea is probably greater than the yield per acre of *all* the land in Great Britain and Ireland."

In this country there is a continual increase of population (for whether we like it or not there is a tendency for people to live longer in these times), and with an annual increase of 300,000 we have great difficulty in finding employment, which, of course, means the capacity to live. If our land surface is insufficient to do this, shall we not eventually be compelled to turn to the sea determined to avail ourselves to the utmost of its products ?

For centuries our lands have been cultivated. We are now entering the era of the cultivation of the seas. The day must soon come when fishing grounds will have to be protected from wasteful harvesting, perhaps even the more restricted and richer submarine banks will eventually be artificially improved by the use of fertilisers and stocked with immature fish. Fifty years have not seen the life of fishery progress. Most likely they havs only ushered in the beginning. In past times competition for tracts of arid territory have brought great nations to heated rivalry, yet these important sea areas have been neglected. Who knows what the age of chemistry will discover for us ? In the last few years a great industry has sprung up from the conversion of certain vegetable products into more useful foods such as butter substitutes. A newly imported food, such as the banana, pours into our country in thousands of tons and maintains a fleet of ocean carriers. Who can say what can be obtained yet from fish oils, fats, gelatines, bones, shells and the very scales of these aquatic animals ? The North Pole and the South Pole have been discovered, how much more useful now to turn man's energies to the exploitation of the products of the Polar Seas; for strange as it may appear, the more temperate and cooler seas seem to be richer in marine life than the tropical waters, and the indications point to immense areas of almost uncharted seas which some day may produce material for many a thriving industry.

In the last hundred years we have seen, from small beginnings, the gradual progress into the fuller exploitation of the coal, iron and oil resources of the land. Coal, iron and brains gave us the steam engine and increased the world's horse power a million fold: the same means will give us perhaps equal progress in utilising the resources of the seas in the coming century. The journey into Polar Seas is not the lonely business it once was. The fisherman of the future will be able to listen to concerts and speeches as he pursues his vocation. He will know the state of the markets before he decides to take his cargo to land, and wireless weather reports will tell him what kind of a fishing he can expect in the near future. When his product is brought to market the manufacturer will know more about the raw material. For instance, the liver oil of the codfish already maintains a large industry, dealing with somewhere about two to three million gallons per annum, yet very little is known of its potentialities. This is a subject which our Government can help through its scientists, for it seems wasteful to sell this product to tanneries when it might have three times the value for medicinal and other purposes. I have just made some experiments in stock feeding, and find an additional growth of 20 per cent. when cod liver oil was added. Our farming industry ought to be able to absorb the whole of this product.

Of the herring, apart from its tremendous value as a food for human beings, its oil content is well worth studying. Unlike other fish the agency of man as a depredator in its ranks has not much effect. Its use as a basal food supply for other fish is so enormous, its breeding capacity so great, that it is unlikely that any very extensive fishing will diminish its numbers. Its territorial extent is so large, going as far as Northern Iceland, that given remunerative prices the quantity taken from the Northern Seas might be five-fold: for as other fish become scarcer there are less of them feeding on it and its eggs: thus it will probably maintain its ranks.

Pressed out, its oil may have peculiar advantages over other oils for certain uses, and the residue is then more assimilative as a food for stock rearing, for once the oil is extracted there is less likelihood of the resultant meal tainting the flesh of poultry, eggs, etc. Its food value is probably higher than that of any of the common fish, and certainly it shows very bad organisation for this most valuable food to be occasionally sold at unremunerative prices. In times of glut, whether in Iceland, Norway, Scotland, or England, herrings ought never to be worth less than ten shillings a barrel for industrial purposes. To talk of hard times and dear food when we have this grand fish often wasted is a reflection on the ability of any people.

Another instance: I have received extremely valuable help from science in obtaining a perfect and extremely tenacious glue from fish, and one containing qualities absent from animal glues. These are only instances. What of sharks, porpoises, dogfish, those wolves of the sea? Full of harm alive they might at least have useful bodies with which to reward us. I know nothing of vitamines, iodines, bromines: these are subjects for our scientists: but I do know that the ocean with its teeming life has not received as much scientific and commercial investigation as it ought to have, for the material is there and the wealth enormous.

There are few chemists with any knowledge of the industry, and of books, where you will find one good one, such as Professor Johnstone's, you will find a hundred on fly fishing. Much more is known of the preference of the genus salmonidæ for certain kinds of flies than of his less handsome though very much more important brother the common cod. The new aquarium in the Zoological Gardens should be a great help in drawing attention to our common fish.

The fishing industry is going through hard times, chiefly occasioned by the high prices of coal; but it is only hard times that teach us the necessity of availing ourselves to the utmost of the by-products and other possibilities of an industry, and probably in a few years time we shall again be on the fair road of prosperity with added resources.

DISCUSSION.

THE CHAIRMAN (Professor MacBride), in opening the discussion, said he supposed some of those present knew that Mr. Neal Green spoke from a wide practical experience of the Fishing Industry, being a trawlowner and factory owner on a large scale in Grimsby. He himself had rarely listened to a more instructive paper than the present one. A large number of serious questions were raised by it and they were fortunate in having several gentlemen present who had first-hand knowledge of the condition of the Fishing Industry. As it was the Chairman's duty to open the discussion, he would like to refer to the points which had struck him as the most important.

The Fishing Industry was the only one of our food industries which had remained in a primitive condition. Roughly speaking, the difference between a savage and civilised state was at bottom a difference between people who gathered food and people who produced food. In fishing they were still in the condition of gathering food, and the question was whether anything in the nature of cultivation of food production was possible. Mr. Green had hinted that considerable improvement in that direction was in sight, but he was sorry to confess that with regard to that question he was himself rather a pessimist. The sea was a thing which was exceedingly difficult to control. No doubt in certain isolated cases, where there was a tract of water surrounded by land the conditions could be controlled, and something could be done to improve the fishing production.

In particular, Mr. Green had alluded to an experiment performed by the Danes in transplanting young fish to the Dogger Bank, with the result that they grew very much more quickly. It was true that that experinent was made, but not by the Danes. It was made by our own scientific men belonging to the Marine Biological Society many years ago. The person who carried out the experiment under the direction of Dr. Allen, was Dr. Garstang, who was now Professor in Zoology at Leeds University. He was glad, however, to think the Danes had followed up those experiments which had been begun by our own countrymen. In the middle of the Dogger Bank there was an area which for some reason was not naturally reached by the fish, and in which there was a very large and abundant fauna of the material on which fish feed. It was found that if small fish were artificially transplanted to that place they would grow more quickly. But such cases were exceptions, and the best hope of getting the help of science in the fishing industry was partly, as Mr. Green had indicated, in the better utilisation of the products of the industry, and partly in enabling the fisherman to find his fish.

One of the most interesting features of the paper was the account which the Lecturer gave of the extent to which that was now being done, and another interesting feature was the study of the life history of the fish, so that they might hope in the not distant future the Board of Fisheries would be able not only to tell the trawl-owners where they were likely to discover the fish, but to predict what kind of catch they would get. Both those matters were now rising above the horizon. It had been shown that the crop of the sea which the Lecturer accurately described as the plankton, determined the subsequent crop of mackerel in the south-west of England, and a thing which they might be able to do in two or three years' time would be to tell the fisherman in February and March what likelihood there was of getting a good catch later on in the season.

Then they had the extraordinary discovery of Dr. Hjört, the Norwegian scientist, with regard to herring, to which Mr. Green had not alluded in his paper. Dr. Hjört showed how the age of herring could be told by the number of growth rings on its scales, and found that a good production of herring only happened once in about 10 years. Yet when the statistics were taken, it was found that the production of one good year was so enormous that it supplied material for abundant fisheries for perhaps seven or eight years running. All these were directions in which science could help.

Mr. Green had alluded to the damage done by seals and porpoises, and while many people looked upon the seal as a harmless and rather beautiful creature, and likened it to a mermaid, he was entirely in agreement with what Mr. Neal Green had said about their being among the "wolves" of the sea. In this country we were imbued with what could only be described as morbid sentimentality with regard to the seal. In the Zoological Gardens before the War there were two large seals which had been presented by the Duke of Bedford, and it was calculated that at pre-war prices it cost as much to keep one of those seals in food as it cost to lodge an ordinary person in the Ritz. Except in the case of the fur-bearing kind, the seal deserved short shrift, and the same applied also to the porpoise.

The last point raised by the Lecturer was the effect of the general rise of prices on the industry. They were still suffering from that extraordinary delusion described by the Dean of St. Paul's, when he said that they had behaved at the Armistice as if they had come into a fortune, instead of having carried through one of the most exhausting and expensive wars in history, and loading themselves with a debt of £8,000,000,000. Everybody was demanding shorter hours and greatly increased wages, but from the point of view of general economy that simply could not go on. If they looked into the state of things before the war they would find capital was earning, when it was in a safe investment, something between 3 per cent. and 4 per cent. interest, which was about the lowest return which would tempt anyone to save; and yet the wages were then vastly less, and it seemed to him there was no evading the conclusion that before they could get on to a safe basis again, a readjustment in wages and hours of work would have to take place.

Mr. G. L. Alward said he had been brought up from his boyhood in the fishing trade and knew every branch of it, and would like, therefore, to congratulate the Author on his paper, with which he agreed in every particular. A good deal had been said about the utilisation of the by-products of fish, but what the British public were concerned about was fish for food, and they never realised the real value of fish for food until the recent terrible war devastated almost everything.

The suggestion of transplanting fish from one part of the sea to another was a suggestion made by a fisherman. He had helped to investigate and examine the fishing grounds of the North Sea, and it was found that in certain parts there were more young fish than could find food and nourishment as they grew bigger, and thereupon it was proposed that some portion of the flat fish, for example the plaice, should be transplanted. The result was that several millions were transferred from the shores on the east side of the North Sea to the middle of the Dogger Bank. Each one was marked, and in a short space of time they were again caught and were found to have grown enormously in two or three years—much more quickly than the same kind of fish grew in the old breeding grounds.

The Fishing Industry in this country had somewhat declined as a result of the war, but it would revive again without doubt. As to denuding the whole of the seas that was absolutely impossible. The artificial hatching of fish had been attempted by him, along with others, and the experiment in hatching out herring had been completely successful.

Mr. Arthur F. Evans could not help feeling that there was something wrong with the Fishing Industry, not indeed in the actual catching of the fish, but in the distribution and handling. There was a want of co-ordination and a want of a co-operative system. The excellent idea as to the utilisation of waste products could not be carried out in an economical and satisfactory manner without thorough co-operation.

He was astonished at the lack of co-ordination in the matter of the prices of fish. For instance, prawns were often offered in fishmongers' establishments at prices ranging from 3d. and 4d. to even as much as 6d. Probably 50 per cent. of the prawns eaten throughout the world were not caught and gathered, but farmed in the Gulf of California on farms, which were simply irrigation ditches in which prawns were fed and reared.

In a district in Hampshire there was a huge series of saltings covering some hundreds of acres, but those saltings had gone out of use. He wondered whether it would not be possible to utilise places of that description for the purpose of the cultivation of prawns or shrimps, which formed, in his opinion, a food of the greatest value weight for weight that it was possible to obtain.

The Americans did not get fresh fish, but obtained codfish from the great fishing industry in Newfoundland, and the American cooks were able to serve it up in a very palatable form. If our 1,000-ton trawlers were to go to the Northern Seas, or perhaps even to the Southern Seas, they would be able to get their fish and salt it and bring it back to this country, but we could not make use of these long-distance fishing grounds until there was some different method of dealing with fish than packing it in ice and squeezing all the life out of it, and then serving it up a slimy soggy mess.

Professor S. B. Schryver, D.Sc., said there was a very large scope for scientific work in connection with the Fishing Industry, and some of the problems had already been mentioned by previous speakers. Mr. Green, in particular, had called attention to the fact that the methods of keeping fish for a long period so that it preserved its flavour were not yet by any means satisfactory. In that alone he could see there was room for prolonged scientific research. Then again, there was the question of the methods of utilising various fish which were not largely used for human food. Altogether there seemed scope for a good many years to come for scientific work, firstly, on the question of the preservation of the fish, and secondly, on the question of the proper utilisation of waste products.

Dr. J. C. Kernot, referring to Mr. Green's experiments on stock feeding, said it was a strange thing that at present the Fishing Industry would not sell fish meal containing more than 4 per cent. or 6 per cent. of oil. A number of experiments had been carried out in connection with fish meal obtained from immature fish, and it was found that that fish meal contained about 10 per cent. of oil, which was very similar in many respects to the cod-liver oil employed by Mr. Green in his experiments.

Another point of great interest was the fact that it had been found possible to obtain from fish skins a product which was very similar to the isinglass obtained from the sturgeon bladder. As a matter of fact in some respects it was superior to isinglass. The price of isinglass in this country was something like 16s. or 17s. per lb., but the product produced in this country was considerably cheaper. This process provided a possibility for a very big industry in England. With one or two exceptions there had not been any attempt to produce from fish offal a gelatine or glue which could compete with the products imported from America, and yet the imported products sold at an enormous price, while the British product was not only cheaper but considerably better than the American.

Mr. Neal Green, in replying to the discussion, said to some extent if the American method of dealing with the marketing of fish were adopted in this country, namely, turning the fish into flakes, to be sold by the packet, it would mark a great step in the stabilisation of prices. The reason for the dearness of fish was mainly owing to the great fluctuations at the port of landing. For instance, in fine weather there was a glut of fish and the prices were low, but in a week's time there might be heavy gales and a scarcity of fish and the prices at the landings mounted up to quite four times as high as they had been a week previously. In view of those great fluctuations in supply the fishmonger naturally looked at the whole thing broadly, and protected himself as well as he could, and in doing so he naturally showed a preference for the higher price. The tendency was, therefore, to stabilise prices at a figure which would prevent his losing money on any day of shortage, and the result was that when fish was cheap he made a big profit.

Another point with regard to the marketing of fish was the question of refrigeration. There again, they came back to the question of the help to be obtained from the scientist. He did not know whether he was very grateful for the advantages he had received from the Board of Agriculture and Fisheries in collecting all those voluminous statistics they had compiled and distributed. For his own part he would not spend money in compiling statistics, but he would spend it on the scientific and industrial side. If a process of refrigeration were discovered which would prevent any deleterious effect on the fish, it would be a very big step towards the stabilisation of prices.

With regard to the question of shrimps and prawns there would be a great advantage to be obtained from the cultivation of these forms of fish. If there were restricted areas where the prawns and shrimps could be cultivated, there would be a better and fresher commodity supplied, and he did not think there would be the same amount of damage done in the North Sea which the small coasting fisherman did at the present time in the way of destroying countless millions of immature fish, which get caught in the shrimpers nets. People were inclined to complain about the damage done by trawlers to small fish, but in his opinion it was nothing like the damage which the inshore shrimper and prawner did.

A hearty vote of thanks was accorded to the author for his paper.

JAVA KAPOK.

The standard kapok, which is the floss, or fibre, produced in the pods of the kapok tree, comes from Java, and is known as prime Samarang. This material has been used for centuries by the natives for filling purposes, but not until comparatively recently has it attained any particular commercial importance. Its admirable qualities were first known to the commercial world about the year 1850, when the Dutch in Java began to export it in small quantities, first to the Netherlands, and then to Australia and the United States. Since that time Java has been the principal, and, in fact, practically the only source of supply, despite the fact that the trees grow wild in many other tropical countries. This is due to the fact that, while in other regions there is a decided lack of a systematic method of harvesting and marketing, the Dutch merchants realized the value and potentialities of the commodity, organized their marketing system, and encouraged the natives to harvest and bring in the crops, thus inaugurating a regular export business.

The greater part of the kapok produced is used for fillers in pillows, cushions, mattresses, and similar articles of upholstery; in fact it has already acquired the rank of the premier filling fibre of commerce. Its uses for this purpose are varied and constantly increasing in number. Because of its filling capacity and durable elasticity, a mattress stuffed with the fibre will resume its original dimensions when any weight bearing upon it is removed, and the weight of a quantity of kapok required to fill a mattress is considerably less than that of any other material similarly employed.

Owing to its buoyant qualities kapok is also used for filling buoyant cushions, swimming wings, water vests, ocean waistcoats, etc.. It will not become matted as is the case with other materials. This utilization is of comparatively recent origin. The fibre now appears to be gradually replacing cork as a buoyant, and government life-saving regulations sometimes require the use of kapok as a filler in life-belts and similar life-saving devices.

The market for kapok will become further extended, it is said, when its value is better appreciated as a filler for surgical dressings. For this purpose it possesses the requisite advantages of lightness, elasticity, dryness, and suitability for dry sterilization.

The utilization of kapok for textile purposes has not met with a marked degree of success. German textile experts have attempted to spin kapok, but the experiment is reported to have been a failure unless the fibre is mixed to a large extent with long staple cotton, since the kapok fibre is short, round, brittle, and straight, while the cotton fibre is long, flat and tough, and possesses a natural twist.

From a report by the United States Vice-Consul at Soerabaya, it appears that only about 6 per cent of the Java crop is estate grown, although conservative estimates indicate that production costs could be lowered very considerably by this method. The cultivation of the fibre on a large scale for commercial purposes is carried on in Middle Java, particularly in the Residencies of Samarang and Solo, where the tree is grown in conjunction with coffee and cocoa plants. The major part of the land devoted to kapok culture is native owned. The lack of proper care in production and marketing at the present time constitutes one of the principal risks and impediments of the industry.

Kapok is one of the few crops that apparently have not been affected by the period of depression following the war. For many years the price has been comparatively steady. It is thought that there will continue to be a good market for this fibre, as the demand becomes constantly greater as a result of its increased appreciation and uses. The outlay in establishing the crop and the upkeep charges are small, and the labour and necessary machinery are inexpensive. The great advantage in kapok cultivation is that the land, in addition to bearing kapok trees, can, by reason of the small amount of shade thrown by these trees, be utilized for a wide range of additional crops.

APICULTURE IN CHILE.

According to a report by the United States Consul at Concepcion, apiculture is a minor industry throughout Chile, with the exception of the desert Provinces of the north, the southern territory of Magellan, and the central zone between Valparaiso and Talca, which lead in the production of honey and wax. In 1921 the Province of Santiago led in the number of hives, with a total of 16,992, and produced 82,400 kilos of honey and 21,100 kilos of wax. The yearly production of honey and wax and the number of hives each year since 1916 is shown in the following table:

Years*	No. of Hives.	Production of	
		Honey.	Wax.
	Number.	*Kilos.*	*Kilos.*
1916.........	115,328	868,700	110,800
1917.........	178,440	474,300	62,200
1918.........	129,466	661,700	103,600
1921.........	123,113	573,600	150,200

*Statistics not available for 1919 and 1920.

The United States continued to be the principal buyer of beeswax, but Germany took the bulk of Chile's honey. Some 70,000 pounds of beeswax were exported to the United States from Talcahuano in 1922, and 35,000 pounds during the first six months of 1923.

The gathering of honey commences in November, and December, and its exportation continues from January to May. The greater part of the beeswax is exported during March, April and May. Beeswax and honey are purchased from the farmers in varying quantities by export houses and brought to warehouses in Talcahuano or Valparaiso for grading and shipping.

CORK AND ESPARTO INDUSTRIES OF CONSTANTINE.

Cork.—The cork forests of the Department of Constantine cover 403 400 hectares out of a total for the whole of Algeria of 453,820 hectares. It may be interesting to compare this area with that of other countries—France 148,680; Turkey, 116,000; Morocco, 230,000; Spain, 225,000; Portugal, 300,000, and Italy, 80,000.

From these figures, writes the British Vice-Consul at Bona in his annual report, an idea can be formed of the important place the Algerian cork trade could take in the world's market. Algeria now furnishes about one-fifth of the world's production.

The value of cork has not risen in proportion to other products owing principally to the fact that the two chief pre-war purchasers were Russia and Germany. The former country used to import a large quantity of cork slabs of all qualities for the manufacture of corks for the vodka trade. As this market is now closed and the German market not re-opened, the consequences have been that, to save the trade, it has been transformed more and more into an industry for the manufacture of corks.

Esparto Grass.—The esparto fields of the Department of Constantine are estimated at 1,250,000 hectares of which 300,000 remain unexploited. The unexploited regions exist to the south of Tebessa and between Kenchela and Batna, and are too far away from the railway for the esparto to be transported. They must wait for development till the much discussed railway for the Djebel-Onk phosphate deposits is constructed. Once this is an accomplished fact there would be a big addition to the amount of esparto shipped at Bona.

PRUNE GROWING IN FRANCE.

Three principal varieties of plums are cultivated in south-western France. The Reine-Claude, or greengage, is generally used fresh, and is shipped principally to Paris, northern France, and England. The annual production of this fruit is normally from 10,000 to 15,000 metric quintals. (1 metric quintal equals 220.46 pounds.) The St. Anthonin plum is shipped largely to England for use in making marmalade. The normal production of this variety is about 10,000 metric quintals annually. The Prune d'Ente is commercially the most important variety, which in dried form becomes the basis of the prune trade.

According to a report by the United States Consul at Bordeaux, the cultivation of the prune d'Ente is concentrated in five departments: The Gironde, Lot-et-Garonne, Tarn-et-Garonne, Dordogne, and Lot. The Lot-et-Garonne furnishes about two-thirds of the entire French production of prunes. This production is extremely variable, depending on climatic conditions and the inroads of insect pests. The normal production of the five Departments mentioned is from 100,000 to 125,000 metric quintals annually. In 1922 the crop was very small, totalling only about 15,000 metric quintals.

The prunes are dried by the harvesters in ovens similar to those used for baking bread, or simply in stoves. The fruit loses from 60 to 65 per cent of its weight through evaporation of water. The dried prunes are sorted, either by hand or by mechanical means, and are carried to the nearest market (the most important are Agen and Tonneins) where the fruit is bought by dealers, re-sorted, and packed.

While the French market, especially in the north, absorbs the greater quantity of the prune crop, about 40 per cent of the production is usually exported to England and other northern countries.

CHINESE GRASS-CLOTH WEAVING INDUSTRY.

The weaving of a snow-white fabric, entirely by hand, from the bark of hemp, is an important industry in China, writes the United States Trade Commissioner at Shanghai.

Grass cloth, known to the Chinese as "hsiapu," or summer cloth, and classified by foreigners as Chinese linen, is a special product of the provinces of Fukien, Kiangsi, Hunan, Szechwan, Kiangsu, and Kwangtung. The cloth is woven from hemp, ramie, pineapple fibre, or from a mixture of these and the bark of hemp. Whatever its constituents, it is excellent in texture and is worn to a considerable extent by both Chinese and foreigners. Compared with the finest silks and satins, the best quality of grass cloth is quite expensive.

The coarse, discoloured hemp fibres are made into cordage, mosquito nettings, bags, and mourning raiment. There is a big demand for the last-named item during mourning periods, when, according to the Chinese custom, even the rich dispense with their silks, and wear the coarsest kind of grass cloth. Sometimes these fibres are woven with cotton yarn into a kind of gauze.

Grass cloth is made in average lengths of about 50 feet, and in widths of from 12 to 14 inches. It is generally offered in 15-piece packages, but in some localities 30 to 50 pieces are bound together. The Shanghai market for this material usually opens in May, 100 pieces constituting the unit for selling. Prices vary considerably.

Chosen and Formosa are the best markets for Chinese grass cloth, although Japanese imports of this article from China have attained some importance. China is attempting to find a larger outlet through improvements in weaving, and by turning out a broader cloth of unrivalled whiteness.

NEW CHINESE MINT.

A mint is now in process of construction in Kalgan, according to a report by the United States Consul at that place. It will be known as the K'ou Pei Mint and will produce Chinese copper coins exclusively. The minting of silver coins will be undertaken after the mint has demonstrated its success in turning out copper coins. The latter are intended for circulation in the Chahar district and in the regions adjacent to the Pekin Sui-Yuan railway.

About 10 acres of land in Kalgan have been purchased, and buildings are now being erected thereon at a cost of about £10,000. Chinese are in charge of all constructional work. The actual installation of the machinery will be done by Chinese labour under the supervision of Dr. C. H. Wang, a graduate of an American university and a metallurgical expert.

The machinery for the K'ou Pei Mint was imported from Japan six or seven years ago. It was originally intended for Shantung Province, but on account of political conditions was never used. The total value of all machinery, furnaces, presses, etc., is said to be about £75,000.

The Kalgan mint when completed will be capable of producing 500,000 copper coins in a single shift of 12 hours.

GENERAL NOTES.

Cultivation of the Oil Palm in Sumatra.—In Sumatra the cultivation of the oil palm is increasing, and several new estates were added last year to the list of producers. The output is still small, but the industry now appears to be well-established. The difficulties at first experienced in extracting the oil are being overcome, and there is every indication, writes the British Commercial Agent at Batavia, that in a few years' time the production of palm oil will be of considerable importance. Producers are finding no difficulty in disposing of their oil at good market prices, and the demand for Sumatra palm oil far exceeds the present output. The estimated output for 1922 of 1,495,000 kg. was exceeded, and the preliminary figures now available show that the actual production was 3,700,267 kg. For 1923 the estimated production is 2,535,000 kg. The production of palm kernels in 1922 was 587,716 kg.

Department of Scientific and Industrial Research.—Mr. F. S. Sinnatt, M.B.E., (Mil.), M.Sc.(Tech.), F.I.C., M.I.M.E., has been appointed Assistant Director of Fuel Research, as from 1st April. He was lecturer in Fuels in the University of Manchester, Faculty of Technology, and also Director of Research to the Lancashire and Cheshire Coal Research Association, and has been in charge of the physical and chemical survey of coal seams which the Association is carrying out for the Fuel Research Board in the Lancashire and Cheshire coal fields.

MEETINGS OF THE SOCIETY.

◆

Ordinary Meetings.

Wednesday evenings at 8 o'clock (Except where otherwise stated):—

May 5 (Monday).—T. Thorne Baker, "Photography in Industry, Science and Medicine." Sir Herbert Jackson, K.B.E., F.R.S., will preside.

May 7.—J. Robinson, M.Sc., Ph.D., F.Inst.P., Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough, "Wireless Navigation." Admiral of the Fleet Sir Henry Jackson, G.C.B., K.C.V.O., F.R.S., will preside.

May 14.—F. C. Ingrams, President of the London Fur Trade Association, "Furs and the Fur Trade."

May 21.—(Trueman Wood Lecture.) Sir William J. Pope, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, "The Outlook in Chemistry."

May 28 (at 4.30 p.m.)—Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Indian Section.

Friday afternoon, at 4.30 o'clock:—

May 2.—Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.R.S., F.I.C., F.C.S., Professor of Organic Chemistry, Imperial College of Science and Technology, "Chemical Research in India." Sir Thomas H. Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S., will preside.

Dominions and Colonies Section.

Tuesday, May 27, at 4.30 o'clock.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Wednesday, June 4, at 4.30 o'clock.—The Rt. Hon. Sir Frederick Lugard, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates."

Monday, June 16, at 4.30 o'clock.—C. V. Corless, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada."

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, May 5 .. Geographical Society, 135, New Bond Street, W., 8.30 p.m. Mr. M. Terry, "From East to West across Northern Australia."

Rubber Industry, Institution of (London Section), Engineers' Club, Coventry Street, W., 8 p.m. Mr. J. Fairbairn, "The Rubber Industry—a Plea for Closer Working."

Farmers' Club, at the Surveyors' Institution, 12, Great George Street, S.W., 4 p.m. Mr. S. R. Whitley, "Improved Methods in the Sale and Distribution of Farm Produce."

Surveyors' Institution, 12, Great George Street, S.W., 8 p.m.

Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 5.30 p.m. Prof.

F. C. Lea, "Scientific Research and Transport."

Engineers, Society of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Mr. C. H. J. Clayton, "Some Factors of Sea Defence Work."

University of London, at King's College, Strand, W.C., 5.30 p.m. Prof. G. Murray, "The Historian Theopompus."

University Extension Lecture, Gresham College, Basinghall Street, E.C., 6.15 p.m. Mr. A. Compton-Rickets, "Personal Forces in Modern Literature." (Lecture I., J. M. Barrie.)

TUESDAY, MAY 6 .. Zoological Society, Regent's Park, N.W.. 5.30 p.m. 1, Mr. R. Broom, "On Some Points in the Structure of the Pareiasaurian Skull." 2, Mr. D. M. S. Watson, "The Elasmosaurid Shoulder-Girdle and Fore-Limb."

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. J. Barcroft, "The Effect of Altitude on Man." (Lecture II.)

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. W. G. Constable, "The History of Decorative Painting in England." (Lecture II.) 5.30 p.m. Prof. J. G. Robertson, "Byron and Goethe." (Lecture II.)

Alpine Club, 23, Savile Row, W., 8.30 p.m. Mr. J. A. Parker, "The Pyrenees."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Dr. C. E. K. Mees, "Tone Reproduction in Photography" (Hunter and Driffield Memorial Lecture)

WEDNESDAY, MAY 7 . Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5 p.m.

Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. (Wireless Section). Mr. L. C. Pocock, "Faithful Reproduction of Radio Telephony."

University of London, King's College, Strand, W.C., 5.30 p.m. Sir Halford Mackinder, "The Communications of the Empire."

Public Analysts, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m., 1, Messrs. J. H. Lane and L. Eynon, "Determination of Sugar in Urine by means of Fehling's Solution with Methylene Blue as Internal Indicator." 2. Mr. J. Considene, "Simple Forms of Hydrogen Electrode." 3. Messrs. K. A. Williams and E. R. Bolton, "Note on the Recognition of Hydrogenated Oils." 4. Dr. A. T. Etheridge, "Estimation of Copper and Tin and Copper-Tin Alloys." 5. Mr. D. W. Steuart, "Notes on the Analysis of Milk Powders and Condensed Milks."

THURSDAY, MAY 8 Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. Annual General Meeting.

Historical Society, 22, Russell Square, W.C., 5 p.m. Miss E. C. Lodge, "An Episode of the English Rule in Gascony during the 13th Century."

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Annual Meeting. Address by the Chairman, the Hon. Sir John Cockburn.

Mechanical Engineers, Institution of (Graduates' Section, N.W. Branch), at the Engineers' Club, Albert Square, Manchester, 7.15 p.m. Mr. C. Eatough, "The Manufacture of Worm Gearing."

Royal Institution, Albemarle Street, W.1. 5.15 p.m. Mr. F. Balfour Browne, "Social Life among Insects." (Lecture II.)

Iron and Steel Institute, at the Institution of Civil Engineers, Great George Street, S.W., 10.30 a.m. Annual Meeting. 1. Presidential Address by Sir William Ellis. 3. Mr. J. P. Bedson, "Continuous Rolling Mills; their growth and development." 2. Messrs. J. H. Andrew and H. Hyman, "High temperature growth of special Cast Irons." 2.30 p.m. 4. Messrs. F. C. Thompson and W. E. W. Millington, "The Plastic deformation of α and γ Iron." 5. Mr. O'Neill, "The effect of cold-work upon the density of α Iron." 6. Messrs. C. A. Edwards and L. P. Pfeil, "The production of large Crystals by annealing Strained Iron." 7. Messrs. A. Westgren and G. Phragmen, "X-Ray Studies on the Crystal Structure of Steel." Part II.

University of London. University College, Gower Street, W.C., 5.30 p.m. Senator Prof. A. Crippico, "Lirici italiani contemporanei." (In Italian). 5.15 p.m. Prof. J. E. G. de Montmorency, "The History of Leagues of Nations." (Lecture I.)

At King's College, Strand, W.C., 5.30 p.m. Mr. A. del Re, "English Influences in Italian Literituro during the 18th Century.' (Lecture I.) 5.30 p.m. Senor Don José Castellejo. "Education in Spain—its Organisation Problems, and Attempts at Reform." (Lecture III.)

Auctioneers' and Estate Agents' Institute, 34, Russell Square, W.C., 3 p.m. Annual General Meeting.

FRIDAY, MAY 9 . Chadwick Trust, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m. Prof. MacBride, "Some Causes of a C3 Population."

Royal Institution, Albemarle Street, W., 9 p.m. Prof. V. F. K. Bjerknes, "The Forces which lift Aeroplanes."

Iron and Steel Institute, at the Institution of Civil Engineers, Great George Street, S.W., 10.30 a.m. Annual Meeting continued. 1. Mr. W. Dryssen, "Recovery of Waste Heat in Open Hearth Practice." 2. Mr. J. Seigle, "Theoretical considerations respecting certain features in the working and efficiency of Reversing Regenerators." 3. Mr. K. Honda, "On the Forging Temperature of Steels." 4. Messrs. K. Honda and K. Takahasi, "On the Indentation Hardness of Metals." 5. Messrs. A. L. Norbury and T. Samuel, "Experiments on the Brinell-tensile relationship." 2.30 p.m. 6. Messrs. G. S. Bell and C. H. Adamson, "Transverse test bars and Engineering Formulæ.' 7. Messrs. E. W. Colbeck and D. Hanson, "The Hardening of Silico-Manganese Steels." 8. Mr. D. J. MacNaughtan, "Hardness of Electro-deposited Iron, Nickel, Cobalt and Copper." 9. Messrs. L. Atchison and W. L. Johnson, "Notes on the testing of Metal Strip." 10. Mr. W. N. Hindley, "Some effects of the penetration of Arsenic and Sulphur into Steel."

Astronomical Society, Burlington House, Piccadilly, W., 5 p.m.

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Malacological Society, at the Linnean Society, Burlington House, Piccadilly, W.

Aeronautical Engineers. Institution of, Engineers' Club, Coventry Street, W., 6.30 p.m. Captain W. H. Sayers, "Some Possible Future Developments in Aeronautics."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Mr. R. W. Allen, "Irrigation Pumping Machinery" (Gezira Scheme).

Sanitary Institute, Town Hall, Tunbridge Wells, 5 p.m. 1. Mr. W. H. Maxwell, "Tunbridge Wells Undertakings"; "Water Bearing Strata in and around Tunbridge Wells"; "Rainfall and Drought in 1921." 2. Dr. F. C. Linton, "Child Welfare Work, retrospective and prospective."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. B. Park, "Picture Making in the Pyrenees and the little known Republic of Andorra: by Mule and Motor."

SATURDAY, MAY 10 .. Royal Institution, Albemarle Street, W., 3 p.m. Dr. F. A. E. Crew, "Heredity and Sex."

Journal of the Royal Society of Arts.

No. 3,729. VOL. LXXII.

FRIDAY, MAY 9, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

20 JUN 1924

NOTICES.

NEXT WEEK.

Wednesday, May 14th, at 8 p.m. (Ordinary Meeting.) F. C. **Ingrams**, President of the London Fur Trade Association, "Furs and the Fur Trade." **Ernest Poland**, Vice-President of the London Fur Trade Association, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

NINETEENTH ORDINARY MEETING.

Wednesday, April 30th, 1924; Mr. Harry Gosling, C.H., M.P., Minister of Transport, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

- Archibald, John Smith, Montreal, Canada.
- d'Erlanger, Baron Emile Beaumont, London.
- Drake, William Allen, Dayton, Ohio, U.S.A.
- Flavelle, Sir Joseph Wesley, Bt., Toronto, Canada.
- Fleming, Alfred, Southsea, Hants.
- Garrigues, H., Copenhagen, Denmark.
- Hodges, Gordon, London.
- Izod, Edwin Gilbert, Johannesburg, Transvaal, South Africa.
- Lynn, Scott, Mem.A.I.E.E., Toronto, Canada.
- Nicholson, Reginald, M.B.E., Midhurst, Sussex.
- Rai, H., Indore, Central India.
- Whitby, Thomas Broom, Nottingham.
- Williams, Frederic N., Shreveport, Louisiana, U.S.A.

The following candidates were duly elected Fellows of the Society:—

- Aisinman, Dr. Semion, Paris, France.
- Crichton, Alexander, New Brunswick, Canada.
- Fazul, Mehr Ali, L.C.E., A.M.I.E., Hyderabad, Deccan, India.
- Fern, William G., London and South Africa.
- Mepham, George S., St. Louis, Missouri, U.S.A.
- Miolée, Willem Frederik, Bulawayo, South Africa.
- Moll, Thomas, Bedford.
- Parsons, Frederick, Massachusetts, U.S.A.
- Robertson, James Alexander, O.B.E., J.P., Cleveleys, via Blackpool.
- Rusk, Professor Rogers D., M.A., B.S., Naperville, Illinois, U.S.A.

A paper on "The Victoria Dock District and its Roads" was read by **Brigadier-General Sir Henry Maybury**, K.C.M.G., C.B., Director-General of Roads, Ministry of Transport.

The paper and discussion will be published in a subsequent number of the *Journal.*

INDIAN SECTION.

Friday, May 2nd, 1924; Sir Thomas H. Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S., in the Chair.

A paper on "Chemical Research in India" was read by **Dr. Jocelyn F. Thorpe**, C.B.E., F.R.S., Professor of Organic Chemistry, Imperial College of Science and Technology.

The paper and discussion will be published in a subsequent number of the *Journal.*

EXTRA MEETING.

Monday, May 5th, 1924; Sir Herbert Jackson, K.B.E., F.R.S., in the Chair.

A paper on "Photography in Industry, Science and Medicine" was read by **Mr. T. Thorne Baker.**

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Friday, February 15th, 1924.

Lord Meston, K.C.S.I., LL.D., in the Chair.

The Chairman, in introducing the reader of the paper, said they would probably suspect him of some exaggeration when he said that it was now 50 years since Sir Richard Dane entered the Punjab as Assistant Commissioner. He commenced in 1874 that long and distinguished career, which incidentally had the effect of endearing him, almost beyond any man of his time, to the people of the Punjab. In 1898 he became Com-

missioner of the North India Salt Revenue, an office which, in those days, was regarded as one of the very few sinecures in India. In Sir Richard's hands, however, it soon ceased to be a sinecure. He took up the work with his accustomed zeal and changed it into a live appointment, indeed so live that when in 1907 the office of Inspector-General of Excise and Salt for India was created there was obviously only one man to fill it. Sir Richard Dane had acquired a command of the subject which was available in the hands of no other person in India at that time. He set to work on that post again with the same zeal and assiduity that had endeared him to his colleagues in other capacities. The speaker did not think the Government of India realised at the time, although it did realise later, the economies which Sir Richard Dane was able to enforce in his control of the combined offices, the enormous stimulus he gave to the revenue, and the influence that he had on the extremely difficult subjects connected with Excise which were then, as now, the focus of controversy. In 1909, however, the Procrustean rule of age came into operation, and Sir Richard Dane had to go. He did not think Sir Richard Dane's labours in India were altogether uninterrupted by lighter pursuits, and he dared say on an afternoon like the present, Sir Richard Dane often thought longingly of the trout streams and the tiger jungles that insisted on forcing themselves in his way during his arduous searches for new salt sources. But he retired, not, however, to sit at home and to flog the rivers of his own beloved country, which he had done with considerable success, but to find a new sphere in which his remarkable genius could manifest itself. Within a few years of his retirement, China found itself looking over the world for someone to carry on the task and maintain the extraordinarily high standard set by Sir Robert Hart. Obviously, in Europe, there was only one man who could do this, and so Sir Richard Dane had to put on his harness again and go out East once more. His career in China was too recent and too well-known to require any eulogy that afternoon, but here he was, having finished his experiences in China and in India, and he had come to talk to the Society on a subject of which he feared few of those present knew very much. He would at once ask him to read his paper.

The paper read was :—

THE MANUFACTURE OF SALT IN INDIA.*

By Sir Richard M. Dane, K.C.I.E.

Commissioner, North India Salt Revenue, 1898-1907, and Inspector-General of Excise and Salt for India, 1907-1909.

In a pamphlet, published in 1884 for the International Health Exhibition and for the Royal Society of Arts, Mr. Manley made the statement that "the salt produced in India, whether from washing salt-soil, or from the mines in the Salt Range in the Punjab, or from the evaporation of sea-water on the coast, was, and is still, of an inferior character, more or less dirty in colour, and containing from 10 to 12 per cent. of impurities." The statement, so far as Punjab rock-salt is concerned, is incorrect ; as this salt, though it is usually pink in colour, is as pure as English salt. Much of the salt made in Rajputana also is of very good quality ; and in some places in the Province of Sind perfectly pure naturally-formed salt can be collected. It is, however, the case that, except in the north-west of the country, India is not well-provided with good salt ; and the salt made from sea-water by solar heat on the coasts of Bombay and Madras has not, up to the present time, been as good as salt made from sea-water by the same process in other countries.

In the South of India salt appears to have been made from sea-water by solar heat from time immemorial. The populous Provinces of Bengal, Bihar and Orissa were also, in former times, supplied with salt made locally on the sea-coast. The climate of Bengal is, however, too moist, and the density of the sea-water in the Bay is too low to permit of the manufacture of salt by solar heat. Low-lying areas were flooded with sea-water ; and, when the water dried up, a saline efflorescence was formed. This efflorescence, with the saline mud and sand below, was collected : fresh sea-water was passed through it, and the strong brine so obtained was boiled down until salt was precipitated.

In the interior of the country the Rajputana sources were worked, and Punjab rock-salt, lying on or near the surface, was excavated ; but transportation was so costly and difficult that salt, made locally from saline earth and from subterranean brine, was used whenever it could be obtained, however impure it might be. Under Native rule a revenue from salt appears to have been derived, mainly from transit duties, which were collected at barriers established for the purpose on all important trade routes. The taxation was progressive : at each barrier that the transporter arrived at duty had to be paid again ; and this system added materially to the difficulty and cost of transportation, and helped to stimulate local production.

---

* Burma is not included.

The manufacture of salt in India, especially in the Upper Provinces, has been so profoundly modified by the policy of the East India Company and of the Government of India under the Crown, that any account of manufacture must largely be a description of that policy. In the early days of British rule, the possibilities of salt as a source of revenue attracted the attention of the Company's servants in Bengal: and, in 1780, Warren Hastings established a monopoly of the production and sale of salt, on behalf of the Government, in Bengal, Bihar and Orissa. Government agencies were established in Orissa and in the coast districts of Bengal: the agent made advances to the salt-makers and purchased the manufactured salt from them at fixed prices; and the salt so purchased was sold to the public on behalf of the Government. The system ensured the production of a supply of salt, which was considered by the Government to be adequate for the needs of the population, and appears to have been well-suited to the circumstances of the time: and for 50 years after the establishment of the monopoly no serious question appears to have been raised as to its propriety. After the withdrawal of the Company's monopoly of Indian trade, foreign salt appears to have been carried to Calcutta for sale as early as 1818-19: but the quantity for many years was small. In 1835-36 the quantity of salt made locally under the monopoly was 162,000 tons, and the quantity of foreign salt imported was 10,000 tons only. The foreign salt at this time was brought by Arabs in their dhows from Muscat and the Red Sea: the Government did not encourage the importation, and English salt merchants took no part in the trade. In 1845-47, however, a determined attack was made on the monopoly by the English salt merchants and by the press. The salt made was bad, as no improvement appears to have been found possible in the native methods of manufacture. The taxation was high, and the salt was very dear; and it was urged that the monopoly was a form of trading, and was, therefore, a violation of the conditions of the Company's Charter. Under pressure of this attack the stringency of the monopoly was relaxed; and the manufacture of salt by private individuals, under a system of Excise, was permitted both in Bengal and Orissa. The duty also was reduced; and greater facilities appear to have been given to importers of foreign salt, as after this the imports rose rapidly. In 1851-52 they amounted to 110,000 tons.

In Bengal attempts were made by private individuals from time to time to make salt for sale, on payment of the Government duty, but they were unsuccessful. In Orissa manufacture was found to be profitable, and was carried on for many years.

The monopoly survived until the Government of India was assumed by the Crown; but, in 1862, it was decided to abolish it and to leave the supply of salt to the three provinces entirely to private enterprise. The agencies were gradually abolished. In the three years ending with 1873-74, when the monopoly stocks were exhausted, the average quantity of foreign salt annually imported was 276,000 tons; and 78 per cent. of this was English salt.

The territory which the Company acquired in 1801 and 1803 to the north-west of Behar (now forming part of the United Provinces) was supplied with salt from the Nuh and Sultanpur salt works in what are now the Gurgaon and Rohtak districts of the Punjab, from works in the Native State of Bhartpur, and from local works for the manufacture of earth-salt. Some salt also was imported from the Sambhar Lake. For more than 30 years salt in this territory was taxed by the company as an item on an Inland Customs Tariff, very much in the way in which it had been taxed under Native rule. The collection under this system of anything more than a nominal duty upon locally-made earth-salt was found to be impracticable. The revenue derived from a number of articles on the Customs Tariff was insignificant: while the collections on imported salt from Rajputana formed the most important item in the total Customs revenue. In 1834, therefore, it was decided to abolish the Inland Customs Houses; to prohibit the manufacture of alimentary salt east of the Jumna; and to collect import and export duties on salt and on some other articles at a Customs Line established along the southern and western border of British territory. In 1838 it was found necessary to relax for a time the prohibition of the manufacture of earth-salt. But in 1843 full effect was given to the new policy. All goods, except salt, sugar and cotton, were exempted from taxation: the manufacture of earth-salt in the territory within the Customs line was made illegal, and smuggling was made a criminal offence.

After the annexation of the Punjab, the Line was carried along the south of that Province to the Indus, and thence along the left bank of that river to Torbela at the eastern limit of the Peshawar district. In 1855-56 the cotton duties were abolished, but the Line was extended to include the greater part of the Central Provinces: and, in 1867, it was further extended round Berar.

The Line was at this time a most notable landmark. It ran from Torbela to a point on the Mahanadi, a distance of 2,472 miles; and was guarded by an army of 12,911 officers and men. Consignments of salt and sugar were liable to examination when they entered the jurisdiction of the Line, which was a zone 10 to 15 miles in width, and were examined at the posts open for trade and traffic, all of which were under European supervision. Wherever it was possible, a hedge was cultivated so as to form a natural barrier; and in places the hedge thus formed was impenetrable.

Within the area thus ringed in, (which, after the annexation of the Province, included Oudh), the manufacture of earth-salt was suppressed. In the Agra and Oudh Provinces suppression was effected with much difficulty. The salt-makers abandoned their hereditary avocation with reluctance; and the difficulty of suppression was increased by the existence of an important saltpetre industry. A factory for the manufacture of crude saltpetre serves equally for the manufacture of earth-salt. In time, however, by the employment of large preventive establishments, suppression was effected. In Oudh, where the locally-made earth-salt had a high reputation, and imported salt was dear owing to the high cost of transportation, the policy of suppressing the local industry was sharply criticised by the Chief Commissioner in 1867. The manufacture of earth-salt was accordingly again permitted under a system of Excise in the Unao district of Oudh and the Jaunpur district of the Agra Province: and an Act was passed to legalise the experiment. The salt, when made, was, however, found to be so inferior to the Bhartpur and Sultanpur salts, which were then in general use, that the Jaunpur salt had to be destroyed, and the Unao salt was disposed of with great difficulty. Manufacture was, therefore, discontinued after one season.

The establishment of the Customs Line produced a large increase of revenue: and, in 1859, the taxation of salt in the Upper Provinces was raised to the rate in force in Bengal, Behar and Orissa. But the Line, though it involved less harassment of the people than the system of Inland Customs taxation which preceded it, was a great obstruction to trade and traffic; and supervision, however close, could not entirely prevent the occurrence of cases of oppression. Within the Line also salt was undesirably dear. It was felt, moreover, to be inequitable that salt should be taxed so much more highly in Upper India than it was in Madras and Bombay. In 1861 the salt duty in the Upper Provinces was 3 Rs., and in Bengal it was 3 Rs. 4as. per maund of $82\frac{2}{7}$ lbs. In Madras and Bombay it was 1 R. 4as. per maund. These considerations led to the abolition of the Line and the equalisation of the salt duties throughout India. The Line was actually abolished in 1879; but the policy was foreshadowed ten years earlier, when, in the Review of the Annual Report of the Inland Customs Department of 1868-69, the Governor-General observed that "the object to be aimed at was the equalisation of the price of salt throughout India." Control of the Inland Customs Department, which up to this time had been exercised by the Government of the United Provinces, was transferred to the Government of India: the management of the mines in the Salt Range was transferred from the Punjab Government to the Department; and the Sambhar Salt Lake was leased by the Government from the Native States of Jodhpur and Jaipur, to which it belonged. For some years after the lease of the lake, the Government officers there posted merely supervised the manufacture and sale of salt: and duty was collected on the salt when it crossed the Customs Line. As transportation was difficult and expensive, and the transporters were harassed by the transit duties which were collected en route, the trade in Sambhar salt did not develop rapidly. In the five years ending with 1868-69, 43,000 tons of Bhartpur salt, 31,000 tons of Gurgaon and Rohtak salt, 20,700 tons of Sambhar salt, and 11,400 tons of Didwana salt were transported annually across the Line into the United Provinces and the Punjab. In the nine years ending with 1877-78 the annual imports of Sambhar salt rose to 29,800 tons, and the imports of Bhartpur salt fell to 37,000 tons. The imports of other salts did not materially vary. When Sambhar was linked by railway with Delhi and Agra in 1875, and arrangements were made to supply salt direct from the lake to traders in the United Provinces, the superiority of the lake salt began to tell. The construction of railways and the imposition of an uniform salt duty irrespective of quality, a measure which is more expedient than just, were important contributory causes of the destruction of many of the less valuable salt sources in Upper India.

By 1875 the abolition of the Customs Line was decided on. In the debate in Council on the Inland Customs Act of that year, Lord Northbrook said that the Line was recognised to be "a great evil," and that he anticipated with confidence the completion of arrangements which would permit of its abolition. The salt sources of Didwana, Pachbadra, Falodi and Luni in Jodhpur and Kachor Rewasa in Jaipur were accordingly leased from the Darbars; and agreements were negotiated with other Native States in Rajputana and Central India, which provided for the closure on payment of compensation of unimportant salt sources, and for the restriction of the outturn of others, which were left open under the management of the Darbars: for the suppression of the manufacture of earth-salt, and for the abolition of transit duties and of all restrictions upon the trade in salt, on which duty had been paid to the Government of India.

The Bhartpur salt works were closed by the Maharaja in 1876-77. He was unwilling to lease the works to the British Government, and said, with truth, that Bhartpur salt could not compete with Sambhar under the conditions which had been created by the construction of the railway, and by the abolition of the transit duties. Compensation was paid by the Government of India to the salt-makers. The Maharaja receives an assignment of Rs. 150,000 a year from the salt revenue; and salt, upon which duty has been paid to the Government of India, is consumed in the State. If the works had been leased, it is practically certain that they could not have been profitably worked; but the closure of works, which were at the time, and probably had been from time immemorial, the principal source of supply for the Agra Province, was a noteworthy incident.

The duty on salt in Madras and Bombay, which had been raised to 1 R. 13as. in 1869-70, was raised further to 2 Rs. 8as. in December, 1877; and, in July, 1878, the Government directed that this rate of duty should be adopted throughout India. The sugar duties were remitted from 1st April, 1878. The Customs Line was removed soon afterwards, but a line of posts along the Indus was maintained until 1896 to exclude Kohat rock salt from the cis-Indus districts.

Of the five minor sources leased from Jodhpur and Jaipur only Didwana and Pachbadra are worked. The salt-makers at Kachor Rewasa were unwilling to make salt for sale to the Government of India. Falodi and the Luni were worked for a time; but without railway communication it was found to be impossible to work them profitably. The Luni, therefore, was closed in 1887-88, and Falodi in 1897-98.

The works at Nuh in the Gurgaon district failed almost immediately after the adoption of this policy. Over 18,000 tons of salt were taken over by the Northern India Salt Department (which took the place of the Inland Customs Department), but nearly all of it had to be destroyed as unsaleable. The Sultanpur works, though they are on a branch of the Rajputana Malwa railway, were practically destroyed by the competition of Sambhar salt before the end of the 19th century.

As a set-off against this destruction of salt sources, two important groups of new salt works were opened in Western India. In 1875, after the construction of the Bombay Baroda Railway, Sir C. Pritchard, who was then in charge of the salt administration in Bombay, concentrated the manufacture of salt, which was scattered along the shores of the Lesser Runn of Cutch, at Government works at Kharaghoda. The salt made is good, and the works now play a very important part in the supply of Upper India.

In Sind, also, when the Salt Department was reorganised and the suppression of the manufacture of earth-salt was undertaken in 1878, some other salt had to be provided to take the place of the earth-salt, which was up to this time the salt commonly used in the greater part of the Province. New works were, therefore, established on the Moach Plain near Karachi by Mr. Maury, of the Bombay Salt Department; and the greater part of the salt consumed in Sind is obtained from these works.

By these measures the arrangements for the manufacture and supply of salt throughout India were placed substantially upon their present footing. The policy of the Government, as laid down by the Secretary of State in 1881, is to permit the freest possible competition between the different kinds of salt; and, so long as an adequate supply of salt is assured, this policy unquestionably conduces to the interest both of the people and of the Government. In the competition quality and cost are usually the determining factors; but sometimes success is determined by preference. People who have been accustomed to consume sea-salt are very unwilling to use any other; and many other instances of preference, some of which appear to be unreasonable, can be given.

The south of India, Berar and the greater part of the Central Provinces are supplied with Bombay and Madras sea-salt. Bengal and Assam are supplied entirely with foreign salt, and Behar also is supplied mainly with this salt. Orissa, where the local salt-boiling industry was suppressed in 1889, is supplied largely with Madras salt, but partly also with foreign salt. Kohat salt, excavated from quarries which are in private ownership, is consumed in the trans-Indus territory; but the Punjab, the United Provinces, Rajputana, Central India, and part of the Central Provinces are supplied from the Punjab mines, the three Rajputana sources and the works on the Lesser Runn of Cutch; and all those sources are under direct Government management. About 8,000 tons of salt are produced annually at the quarries in the Native State of Mandi in the Himalayas, the Sultanpur works and the few works that were not closed in Native States in Rajputana and Central India; but this contribution is comparatively insignificant. Sind also is supplied from sources which are under direct Government management.

The trade in salt is encouraged. Foreign salt can be bonded without payment of duty in public warehouses: in Bombay and Madras credit for payment of the duty is allowed to merchants executing a bond and depositing adequate security; and in Northern India and at Kharaghoda a so-called Through Traffic system has been most efficacious in reducing the price of salt to the consumer. Under this system traders are able to obtain salt direct from the sources without the intervention of middlemen, by depositing the price and duty and a small fee for bagging and clearance in any Government treasury or authorised Post Office, and by sending a receipted indent with a supply of bags to the officer in charge of the source. Before the war over 2,500 dealers purchased Punjab rock-salt, and about 2,000 purchased Sambhar and Pachbadra salt, direct from the sources; and in the nine years that I was Salt Commissioner only one of the thousands of transactions that took place formed the subject of legal proceedings.

In the three years ending with 1921-22, the total annual outturn of salt in India was 1,454,000 tons; and Bombay and Madras sea-salt represented 58 per cent. of this total. The larger quantity of salt is produced in Madras. The present normal annual output of salt in Bombay is about 370,000 tons; in Madras it is about 450,000. But in Madras, with its large population and high rate of consumption per head, salt is made mainly for local consumption; and only about 54,000 tons a year are exported to the adjacent parts of Orissa, the Central Provinces and the Native State of Haidarabad. From Bombay, on the other hand, about 70 per cent. of the salt produced is exported for consumption in British districts and Native States outside the Presidency.

Much, if not most, of the salt made in both Presidencies contains 15 per cent. or more of magnesic salts, moisture, dirt and other impurities. The manufacture of salt by the evaporation of sea-water by solar heat may be a very crude process, and may also be a skilled industry; and up to the present in India it has not been found practicable to produce first-class sea-salt. But where the two kinds of salt meet in competition, Bombay salt is preferred. For many years Bombay salt has been sent by sea to Malabar; but, in or about 1890, after the construction of the Southern Mahratta railway, it displaced Madras salt in the Native State of Mysore and the Deccan districts of the Madras Presidency. The superiority of Bombay salt appears to be due partly to natural advantages and partly to a difference in administrative methods.

In Bombay, with the exception of some Government works at Dharasna in Gujarat, all the important sea-salt works are concentrated in the vicinity of Bombay.

The works are in creeks, where they are protected from the sea; and are mostly below the level of high tides, so that the reservoirs and pans can be filled by flow, and very little lifting of the brine is necessary. In Madras the works are scattered along the East Coast from Ganjam to Tinnevelly; and there are wide differences between the works in the matter of climate, soil and brine supply. Uniformity of treatment is, therefore, impossible. The coast line does not appear to be specially suited for salt manufacture. The soil in many places is sandy, and it is difficult to prevent sand from being scraped up in the pans in admixture with the salt. Much lifting of the brine also is necessary; and this does not conduce to the manufacture of good salt.

In neither Presidency is there a separate Salt Department. In Bombay salt is combined with Customs and Excise. Until 1917-18 there was a Collector of Salt Revenue; but the Collector had certain Customs and Excise duties to perform. The appointment has now been abolished: the Commissioner of Customs, Salt and Excise has been placed in direct charge of the production and distribution of salt: and the Excise and Salt staffs have been amalgamated. In Madras there is a combined Excise and Salt Department.

In Bombay, except at Dharasna, the manufacture of sea-salt is a private industry carried on under license; and the functions of Bombay Salt Officers are confined to seeing that salt made is properly stored, and that duty is paid before it is removed from the store. The manufacturers, many of whom are capable business men, are allowed to manage their works in their own way: the salt made is their property; and the prices at which it is sold are fixed by them with the purchasers without Government interference. In Madras, on the other hand, the Government take a direct part in manufacture. For many years there was a complete Government monopoly of the purchase and sale of salt. Then for a few years manufacture under a system of Excise was tried. This was held to have failed: and a conjoint system of Monopoly and Excise was introduced in 1888. At some works salt is made under the supervision of Government officers for sale to the Government. At others it is made and sold by private individuals on payment of the fixed duty. After some years at some of the works a system of modified Excise was introduced. Under this system a licensee is permitted to make salt for sale, but the Government has the option of purchasing the whole or part of the salt manufactured at a specified price. There are, therefore, three different systems at work at the same time. The Government and the Board of Revenue have made many attempts to improve the quality of the manufactured salt, but their efforts have not up to the present been very successful. A combined Excise and Salt Department is not well qualified to handle the subject. It is impossible to expect an officer, who has been employed upon Excise work in the interior of the country during the best years of his life, to develop into a salt expert when he is placed in charge of factories on the coast; and in a combined Department cases of this kind must frequently happen, even if they are not actually the rule. The association also of salt with Excise has resulted in unnecessary preventive zeal; and manufacturers are hampered in their business and the quality of the salt manufactured is impaired by the unnecessary stringency of the regulations enforced to protect the revenue.

It is remarkable how little Indian-made salt is sent to Calcutta for sale, though Bengal is now supplied mainly with sea-salt made in other countries. For many years some salt has been sent from Bombay to Calcutta, but the trade shows no tendency to expand. In the three years ending 1873-74, the average annual export was 16,000 tons; at the beginning of the war it was 34,000; and in the three years ending with 1922-23 it was 21,000 tons. In the past two years 38,000 tons of Madras salt have been exported (mainly, if not entirely, from Tuticorin) to Calcutta. In the south of the Presidency, where there is a long manufacturing season, it may be possible to produce salt suitable for the Calcutta market.

The Punjab Salt Range ranks next to Sambhar as the most important salt source in Upper India; and potentially it is perhaps the most important, as the supply of salt which it contains is practically inexhaustible. The Mayo mine at Khewrah, from which the great bulk of the salt is excavated, is one of the largest salt mines in the world; and 800 men, women and children are at present employed in connexion with it. The average annual output of Punjab rock-salt in the five years ending with 1921-22 was 155,000 tons; and 85 per cent. of this came from the Mayo mine. The mine is on the site of old Sikh workings, and, for some years after the annexation of the Punjab, salt was excavated by haphazard methods, as it had been in the time of the Sikhs, without either technical knowledge or any clear idea of the lie of the salt. But in or about 1871 Dr. Warth, a German chemist and geologist, whose services had been secured by the Government of India, was posted to Khewrah. Dr. Warth had some knowledge of salt-mining in Germany; and, in 1872, he prepared the plan upon which the mine has since been worked. I have not been at Khewrah for at least 14 years; but the following description of the working plan is, I think, substantially accurate. The dip of the salt seams is, approximately, from north to south; and the strike is from east to west. The hill is divided into alternate sections of 40 feet and 25 feet along the line of the dip. The 40 feet sections are the working blocks and the 25 feet sections are the pillars by which the hill is supported. The main entrance of the mine is a tunnel driven into the hill from east to west, at a right angle to the dip, until the salt is reached. The salt is excavated in large chambers, along the dip, in the 40 feet sections, until it is worked out. No excavation, except tunnelling and shafts for ventilation, is permitted in the 25 feet pillars. The workings have been enormously extended, and the salt has been attacked from tunnels driven parallel to and at a lower level than the main entrance; but I think that I am right in saying that all workings are governed by the same broad principles. The excavated salt is brought from the workings to tram-lines in the tunnels, and is stacked there at convenient centres in wheeled trucks. These are dragged to the mine mouth, and from there are run down to the depot at the railway station on tram-lines. In former days the mining was done by men, and the salt was carried by women up the slippery pathways by the sides of the chambers to the tram-lines. Now a haulage engine, driven by compressed air, is used to lift the salt to the tramways; and light locomotives have taken the place of mules to drag the trucks to the mine mouth.

The mantle of Dr. Warth descended upon Mr. Bolster, an Irishman, who went to India as an usher in a school, and who exchanged the profession of teacher for a post in the Salt Department. He learnt how to use a theodolite and to make surveys and plans of the workings, and he acquired a sufficient practical knowledge of building to be able to supervise without any professional assistance the construction of masonry lining for the tunnels in the mine and of houses for the European staff. For 30 years, with one short interval, when he was employed at Sambhar, he managed the mine as Superintendent and as Assistant Commissioner in charge of the Division with great skill and with unwearied enthusiasm. The heat at Khewrah in the summer is very great, and I think I am right in saying that in the whole of his long service Mr. Bolster did not once have long leave.

Another mine is worked at Warcha to the west of Khewrah; and a third mine has recently been opened at Kalabagh on the right bank of the Indus, where the salt lies near the surface, and has been quarried from the time of the Emperor Akbar. These, however, are merely subsidiary sources of supply.

Kohat rock-salt is also found in enormous quantities on and near the surface; but it is inferior in purity, appearance and flavour to Punjab rock-salt, and is also more distant from the markets. It is, therefore, practically of no use for the supply of Northern India cis-Indus. About 22,000 tons of this salt are excavated and sold annually in the trans-Indus territory.

The Sambhar salt lake is situated in a depression in the schists of the Aravallis. When the lake is full the length from east to west is about 20 miles, and the width from 1½ to 7 miles. In the hot weather, in a normal season, the lake dries up or recedes to a shallow pool in the centre. Under Native rule, and for some years after the lake was leased, surface brine only was used; and the manufacture of salt was entirely dependent on the character of the season. Manufacture commenced as soon as the weather permitted, and ceased when the brine receded so far that it could no longer be conveyed to the pans and kyars on the edges of the lake in the small channels, which were constructed annually for the purpose in the bed of the lake. At this time large quantities of salt formed spontaneously in the lake bed. To facilitate this formation, the surface brine was held up in suitable places near the storage grounds by low enclosing walls, made annually of grass and mud; and within these enclosures the salt was deposited. As recently as 1894 the quantity of salt manufactured in this way in a "fair average year" is said to have been 37,000 tons at least. This "Lake salt," as it was called, was inferior to the salt made on the edges of the lake in pans and kyars, but it was good edible salt.

"Pan salt" is made by professional salt-makers in shallow evaporating pans, constructed on the edges of the lake from the lake mud. These salt-makers contract to supply salt to the Department, and the salt is sold by the Department to the public. In former days the pans were filled with surface brine, but in recent years subterranean brine, obtained from pits dug by the side of the pans, appears to have been commonly used. "Pan salt" is good, but is inferior to "Kyar salt," as it is small in grain and the crystals are less perfect.

"Kyar salt" is made under direct Government management by workmen employed and paid, until recently, by Government officers. Contract labour has now, I understand, been substituted. A kyar consists of several deep evaporation pans, which are protected from the lake waves by walls or embankments of rough masonry and mud. Brine is admitted to the pans to a depth, usually, of about 15 inches, and is slowly evaporated by solar heat. After extraction of the salt, the bittern from the pans is run back into the lake. Kyars are said to have been in use when the lake was leased, but this form of manufacture has been much developed since the lake has been under management. "Kyar salt" is superior to "Pan salt," and the outturn is more certain. The tendency at present, therefore, is to rely more and more on the kyars. In 1921-22 Kyar salt formed 85 per cent. of the total outturn.

A serious defect of Sambhar has been the precariousness of the supply. In 1892-93 the monsoon rains were heavy, and the weather in the manufacturing season which followed was unfavourable. The total outturn of salt was, therefore, 3,300 tons only. In 1884-85 also there was a flood, and the outturn was 14,000 tons. On the other hand, in 1883-84, which was a favourable year, the outturn amounted to 263,000 tons, and most of this must have been lake and pan salt.

To fill the kyars in a season of short rainfall pumps have been used for many years; and, since 1906, subterranean brine has been extensively used to supplement the surface brine. When the shortage of salt occurred during the war, important measures were taken to increase the outturn of Sambhar. Brine reservoirs were constructed at both ends of the lake: and to ensure the maintenance of the brine supply at the eastern end, which is the more productive, a dam has been constructed across the lake from north to south at a cost of £36,000. Low-lift pumps have been obtained from Europe, and to work the pumps the Settlement has been electrified. The arrangements for loading and transporting the salt by railway from the lake have also been much improved. The methods of manufacture have been revolutionised. The effect on the productiveness of the lake and on the quality of the salt remains to be seen.

Sambhar salt contains 95 to 97 per cent. of chloride of sodium. It is not as pure as Punjab rock-salt, but is preferred to it throughout a large area in Upper India. The outturn of the lake at present is about 200.000 tons a year.

Didwana and Pachbhadra are worked as subsidiary sources to Sambhar. The popularity of Sambhar salt is so great and the cost of manufacture so low, that, if it were sold at cost price, the Didwana and Pachbadra sources would be destroyed. Sambhar salt is, therefore, sold, above cost price, at 4 annas a maund, and the other salts are sold below cost price: Didwana at 2 annas and Pachbhadra at 1a. 6p. per maund. The profit on Sambhar covers the loss on the other salts. At both these sources salt is made entirely from subterranean brine. In the five years ending with 1921-22, the average annual outturn of Didwana salt was 14,900 tons, and of Pachbhadra salt 33,400.

The Kharaghoda works are a very important salt source. In the five years ending with 1921-22 the average annual outturn was 136,000 tons, nearly equal to the outturn of the Punjab mines. The salt is made entirely from subterranean brine, obtained from wells sunk in the shore of the Lesser Runn of Cutch. The salt is made by professional salt-makers, but the land is the property of the Government, and the salt is made for sale to Government at a fixed price. The method of manufacture is peculiar. Only one pan is used. This is filled with brine to a depth of four or five inches, and, after exposure to the sun for some days, salt begins to form. This, however, is not extracted, but is broken up and raked over. Fresh brine is then admitted, and the process is repeated until the crop of salt is considered to be ready for extraction. This is usually in about five months' time from the date of commencement of manufacture. The salt is good, as the supply of brine is skilfully regulated so as to prevent the deposit of inferior salts. It forms in large hard lumps very free from moisture, and finds favour in places where there is a moist climate. It is known in the trade as Baragra. The works are laid out so as to facilitate the storage and transportation by railway of the manufactured salt; and the authorities of the Bombay Baroda railway have always taken a benevolent interest in the source.

The works in Sind, in normal times, merely supply salt for consumption in the province, but Sind as a source of supply appears to have great potential importance. The Moach Plain, about seven miles to the west of Karachi, on which the Maurypur works exist, is commanded by the sea, but the salt is not made from sea-water in the ordinary way, and the works appear to have been established on the Kharaghoda model. Embankments protect a portion of the foreshore between ordinary and spring-tide levels. At spring tides sea-water is admitted to this area and is allowed to sink into the sand. Pits are dug, and, the brine entering them, which is the sea-brine strengthened by leaching of the salt accumulated in the sand, is lifted and evaporated. Maurypur salt has a good appearance, with hard, well-formed crystals, very superior to any Bombay and Madras sea-salt that I have seen. There appears also to be no reason why sea-salt should not be made on the Moach Plain in the usual manner. Both the climate and the locality appear to be favourable.

In the Thar and Parkhar district adjoining Rajputana there are numerous salt lakes, and at two of these lakes there are large deposits of naturally-formed salt of great purity. Without a railway, however, these deposits cannot be utilised for export.

For more than 30 years the policy, which was adopted in the years 1876-81, was remarkably successful. Drastic measures had been taken, but the people throughout Upper India were supplied in exchange with salt of a quality far superior to that to which they had been accustomed; and, in many places, owing to the construction of railways, salt was much cheaper than it had ever been before, notwithstanding the high rate of duty that was in force. In 1889 a proposal to place all the Salt Departments under one head was considered by the Government of India, at the suggestion of the Secretary of State. It was seen to be a defect on the existing arrangements that the experience of one Department was not utilised in the others: and the equalisation of the salt duties and the importance of the revenue as a financial reserve of the Imperial Government were suggested as reasons in favour of the proposed arrangement. The Madras Government, however, urged strongly the inadvisability of depriving the Local Government of the control of the administration; the advantages of local management were held to outweigh the drawbacks involved in the existence of several different controlling authorities; and the proposal was not approved.

For many years there was no suggestion of any possible shortage of the supply. The rivalry between the different departments and the different sources ensured the issue of Government salt to the public at the lowest possible price. In some cases, owing to this rivalry, salt was sold below cost price, and revenue was needlessly sacrificed. This, however, was a small matter. As the population increased, the consumption of salt increased throughout India, and an increasing revenue was secured with such facility that an idea was not unnaturally created that nothing more remained to be done. Owing to the reduction which had been effected in Upper India in the price of good salt, the prevention of the illicit manufacture of inferior salt had become a matter of quite secondary importance; but in the past prevention had loomed large in the salt administration, and when the time came for some change in the administrative arragements, the supposed importance of prevention helped to obscure the issue. A salt tax, in so far as it represents the appropriation of a share of the profit of the producer, the transporter and the vendor, while the prices of salt are kept low by an efficient administration, is an excellent tax in an Oriental country. When poor people are prosecuted for making coarse and inferior salt for their own consumption, a salt tax is oppressive. The Government had accepted direct responsibility for the supply of salt to a large and increasing population in Upper India: and, in 1902, when I had been in charge of the Northern India Salt Department for three years, I formed the opinion that the adequacy of the supply was not sufficiently assured. The Sambhar lake was the principal source of supply for the greater part of the United Provinces. The enthusiasm and devotion to duty of Messrs. Ashton and Lyon, who had held charge of the lake for many years, rivalled the zeal and devotion to duty of Mr. Bolster at Khewrah, and they had both had much experience of salt questions. Both these officers were decidedly of opinion that there had been a marked decrease in the productiveness of the lake. The disappearance also of the spontaneously formed Lake salt, which had been collected in large quantities as recently as 1892-93, was decidedly ominous. At this time it was an article of belief in the Department that first-class Sambhar salt could only be made from surface brine; and the possibility of working Sambhar, like Didwana and Pachbhadra, had not been considered. The matter was represented to the Government of India, and the Geological Department was requested to investigate the question of the origin of the salt and of the possibility of it becoming exhausted. While this investigation was proceeding, I put forward a proposal to place the arrangements for the supply of salt to Upper India upon a more satisfactory footing by the amalgamation of the Northern India and Bombay Salt Departments, and the formation of a strong Department, possessing special knowledge, and dealing mainly with production. A Committee was appointed in 1903 by the Government of India to consider and report on the matter. I had not at the time, and have not now, any doubt that the amalgamation of the two Departments would have conduced to greater efficiency in the administration of the competing salt sources and to the development of other possible sources of supply. Unless, however, the importance of the supply question was realised, there was much to be said for the view taken in 1889; and I failed to convince either my colleagues on the Committee or the Government of India that the importance of the supply question necessitated the proposed change. A majority of the Committee recommended that Sind, where there is a small local Customs and Salt Department, should be placed under the Commissioner of Northern India Salt Revenue; and the Government of India were disposed to act upon this recommendation. But the Bombay Government was so strongly opposed to the proposal that the matter was subsequently dropped. A recommendation, made by the Committee, that additional sea-salt works should be opened in Bombay, as the annual average production of sea-salt (290,000 tons) was not sufficiently in excess of the minimum annual sales (257,000 tons) to preclude the possibility of a shortage in the supply, was at first accepted by the Government of Bombay, and a site for the works was selected. But difficulties were experienced in finding lessees who would accept the required conditions; and, after the matter had dragged on for some years, a favourable manufacturing season in 1911-12, in which 438,000 tons of sea-salt were produced, caused the Bombay Government to change its mind and drop the project. The existing works could, it was thought, produce without difficulty in an ordinary year 400,000 tons of salt; and the interests of the public might safely be left to the salt manufacturers and traders.

The investigation of the resources of the Sambhar lake, which was made by Mr. (now Sir T.) Holland, showed that there was no reason to anticipate any failure in the supply of salt from the lake for many years. Samples of silt, taken at regular intervals from the bed of the lake, were analysed by Dr. Christie of the Geological Department. From the results of these analyses it was estimated, in 1905, that in the upper 4 feet of the lake silt, over an area of 68 sq. miles, there was an accumulation of 18 million tons of sodium chloride, and that in the upper 12 feet there were 55 million tons. The disappearance of the salt, which formerly formed spontaneously in the bed of the lake, was ascribed to a rise in the level of the silt: and the broad conclusion arrived at was there was enough salt in the uppermost 10 feet of silt "to supply the requirements of this section of the Salt Department for 250 years."

The origin of the salt in the lake has formed the subject of much interesting scientific discussion. Put briefly, Sir T. Holland's theory is that the salt in Sambhar and in other depressions in Rajputana, is not derived from rock-salt deposits or from subterranean brine, but has been blown in from the sea and from the Runn of Cutch in minute particles by the violent westerly winds, which precede the south-west monsoon, and that the salt, thus distributed over the country, is washed into the lake and other depressions by the feeder streams during the rains. The reasons urged in support of the theory are to me convincing; and the salinity of Sind and the south-west Punjab, which have no rock-salt deposits, and are similarly exposed to strong salt-bearing winds from the sea, appears to corroborate the theory.

Experiments made at Sambhar, after the investigation, showed that subterranean brine can be used in admixture with surface brine in the kyars, and that good saleable salt can be made from subterranean brine only. A failure of supply in a dry season is rendered less likely by this discovery.

For some years after this, the demand for salt in Upper India was adequately met from the Rajputana sources, the Punjab mines and the Kharaghoda works; and, so little was the possibility of trouble foreseen, that there was, as I understand, at one time some talk of abolishing the Northern India Salt Revenue Department.

The war completely upset the arrangements for the supply of salt to Bengal and Upper India. The annual imports of foreign salt at the beginning of the war were about 560,000 tons. English salt had been displaced to a great extent by salt made at Aden and on the shores of the Mediterranean by the evaporation of sea-water by solar heat; but the imports of English salt (133,000 tons) still exceeded those of any other kind. Aden imports, however, were not far behind, and the imports from the Red Sea, Port Said and Spain were also very large. For the first two years of the war imports were maintained. In 1915-16 they amounted to 525,000 tons, of which 120,000 tons were English. In 1916-17, owing to the shipping difficulty, they fell to 393,000 tons, and, in 1917-18, they fell further to 317,000 tons. The supply of German salt, which was about 5 per cent. of the total imports, was, of course, cut off. The imports of English salt did not entirely cease; but in 1917-18 they fell to 12,900 tons. The imports from Spain and the Red Sea ports also fell off; and a complete failure of supply was only prevented by an increase of the imports from Aden and Port Said. In 1920-21 the imports were large (595,000 tons); but in the four years from 1916-17 to 1919-20 there was a shortage in the imports of foreign salt of 693,000 tons, and the Salt Departments of India, disunited and imperfectly organised as they were, could not for two years do anything to make good the deficiency. To complicate matters, in Bombay and in Northern India the monsoon rains were heavy in 1916-17 and 1917-18; and a wet season is unfavourable for the manufacture of salt. The total production of salt in India in both these years (1,301,062 and 1,244,615 tons) was below normal; and it was not until the summer of 1918, when the very large quantity of salt (1,997,229 tons) made in that year came into the market, that the scarcity was to some extent relieved. The outturn of salt at Sambhar in 1916-17 amounted to 97,700 tons only, and in 1917-18 to 169,000 tons. In 1918-19, which was a favourable year, 426,000 tons of salt were manufactured. The output of the three years was, therefore, in excess of the average, which is now about 200,000 tons a year; but the partial failure in 1916-17, at the time of the greatest shortage, helped to create a panic. The other sources under the control of the Northern India Department maintained, but did not materially increase their production. Bombay was unable to render any assistance. At Kharaghoda in the four years from 1916-17 to 1919-20, the average annual outturn was 115,000 tons only, owing to unfavourable weather, a scarcity of labour, and to a severe outbreak of influenza in the miners' village in 1918-19. In 1919-20 the outturn was increased to 183,000 tons, but by this time the worst of the crisis was over. The sea-salt works failed badly. The decision not to open more works was wrong, and fate was adverse. In the six years ending with 1914-15, the average annual outturn of sea-salt was about 370,000 tons; but in the three years ending with 1917-18, instead of the 400,000 tons which it was estimated that the works could produce without difficulty in an ordinary year, the average annual outturn was 329,000 tons only. Bombay salt almost entirely disappeared from the Calcutta market.

Madras also gave no assistance. At the beginning of 1916-17 stocks in the Presidency were low, but strenuous measures were taken to increase the output and provide salt for Bengal. Large extensions of the salt-works were sanctioned, and men of substance were encouraged to enter the business: and, in 1918-19, the enormous total of 631,000 tons of salt was manufactured. But the inferiority of Madras salt made it unacceptable in the Calcutta market, even when the scarcity of foreign salt was at its height; 11,000 tons of Madras salt reached Calcutta in 1915-16 and 14,000 tons in 1916-17; but in 1917-18 the imports fell to 5,000 tons, and in the next two years they ceased altogether. In 1917-18 Madras salt is said to have fetched in Calcutta only half the price of Aden and Port Said salt. This failure of the attempt to supply salt to Bengal appears to have opened the eyes of the authorities; and, in the annual report of the Board of Revenue for 1920-21, some of the reasons which have hitherto prevented the production of good salt in Madras are stated with great frankness and cogency.

As was natural in the circumstances, the prices both of foreign and Indian salt rose enormously, and the rise in prices extended to Bombay and Madras, although there was not at any time in the south of India any serious shortage of salt. Wild speculation took place in indents for salt from the Northern India and Kharaghoda sources. At the beginning of 1918-19 duty and price had been paid to the Government for 474,000 tons of salt from Sambhar and 259,000 from Khewrah in excess of the supply which was available. One speculator paid in Rs. 3,000,000. A salt tax is an iniquitous impost, but to make money out of the public by the exploitation of a monopoly is legitimate commercial enterprise! The system of sale from the sources direct to the public, which had been worked so successfully, completely broke down. Most strenuous measures were taken by the Government under the Defence of India Act for the protection of consumers; but the scarcity and dearness of salt in Upper India must have caused much inconvenience and hardship.

In Bombay vigorous measures were taken by Sir G. Lloyd's Government to increase the production both of Baragra and sea-salt. The development of the proposed new sea-salt works was ordered in 1917: difficulties with licensees were overcome, and the construction of works calculated to produce eventually 74,000 additional tons of sea-salt was commenced in the following year. Projects also were sanctioned for increasing the outturn of Kharaghoda and of the Government sea-salt works at Dharasna by 50 per cent.; and the remuneration of the Kharaghoda salt-makers was increased, and the conditions under which they live were improved, so as to prevent in the future the shortage of labour, which in the years from 1916 to 1918 had so much hampered the production of Baragra salt.

The salt-makers were the only people in India who benefited by the shortage of salt. The remuneration of these people had not been increased in proportion to the rise in prices which has taken place in India in recent years. A saline tract is an arid and disagreeable place, good water is often very difficult to obtain, and the occupation is by no means an easy one. Their remuneration has now been increased, and the necessity for supplying them with good water and for improving their conditions of life appears to have been generally recognised throughout India.

As regards the supply of salt in the future, the measures taken by Sir G. Lloyd's Government in Bombay appear to be very judicious, but, in my opinion, real efficiency cannot be secured without much greater specialisation in the matter of production than has hitherto been considered necessary. A supply of salt which was sufficient in 1881, for a population of 253 millions, is obviously inadequate for a population of 318 millions; and it is not desirable that India should be dependent to so great an extent upon foreign salt. From "India in 1923," by Professor Rushbrook Williams, it appears that the Government of India propose to provide against any possible failure of supply in Upper India in the future by doubling approximately the annual output from the Punjab mines and Sambhar; and, so far as the mines are concerned, the wisdom of this policy cannot be questioned. As regards Sambhar, however, the case is not so clear. The measures which have been taken will probably make it possible to increase largely the annual outturn of salt at the lake, but is it wise and is it fair to the Darbars, to whom Sambhar belongs, to work the lake to an extent which may cause a diminution of the supply, or a serious deterioration of the quality of salt, if other sources can be found which will provide a substantial share of the quantity of salt annually required in Upper India? There appears to be some misconception as to the result of the investigation of the resources of the lake, which was made in 1902-5. Sir George Watt, in the "Commercial Products of India," published in 1908, says that the Records of the Geological Survey for 1905 contain a "highly instructive refutation of the opinion that the supply from Sambhar was decreasing;" and Mr Fergusson, the Commissioner of Northern India Salt Revenue, in the annual report of the department for 1917-18, says that the investigation "demonstrated the groundlessness of the apprehensions that the supplies of salt might be becoming exhausted," and accepts without question the view that the disappearance of the spontaneous salt is due to a rise in the level of the silt. A little salt is brought into the lake every year during the monsoon by the feeder streams, but the quantity brought in cannot compare with the quantity taken out. The supply of salt is, therefore, certainly decreasing, and the question is: Is it decreasing at a rate which may become dangerous? Personally, I am quite unable to admit that the inflow of silt, which is supposed to have been responsible for the disappearance of the spontaneous salt, can have been anything more than a contributory cause of it. The Menda, which is the principal feeder of the lake, runs through sandy soil, and has, from time immemorial, discharged enormous quantities of sand and silt into the lake. The circumstances of the past 30 years have not differed materially from those of previous years, and spontaneous lake salt was collected in large quantities as recently as 1892-93. The disappearance of this salt is, in my opinion, mainly, if not entirely, due to the fact that there is less salt than there was in the uppermost layer of the lake silt. It has, however, been demonstrated that good salt can be made in the lake from subterranean brine, and unless the brine deteriorates the manufacture of salt at Sambhar from subterranean brine can apparently be carried on indefinitely at Sambhar, as it is at Didwana and Pachbhadra. This, however, is a point which needs careful investigation. Sambhar brine contains sulphate and carbonate of soda in addition to chloride of sodium; and if the percentage of these salts increases beyond a certain point Sambhar salt will be spoiled. The chloride of sodium is taken out in large quantities, and the sulphate and carbonate of soda are, as far as possible, left in the lake. In 1904 Sir T. Holland arranged to have samples of the lake brine taken from different places in the lake periodically analysed and the results averaged in five-year periods. An analysis of the samples for 1907-11 and 1912-16 has been completed by Dr. Christie with the following result:—

LAKE BRINE.

	Cl.	SO_4	CO_3
1907-11 mean	86.09	9.94	3.97
1911-12 ,,	85.38	10.84	3.78

SUBTERRANEAN BRINE.

	Cl.	SO_4	CO_3
1911-12 mean	83.18	12.32	4.50
1911-12 ,,	81.07	13.88	5.05

In the words of Mr. Pascoe, the Director of the Geological Survey, from the point of view of the salt manufacturer the results show a deterioration, the lake brine and the subterranean brine both having at the end of the period a lower percentage of sodium chloride in the dissolved salts than they had at the beginning. An analysis of lake brine made by Dr. Warth in 1869-70, showed the following percentages:—Cl. 90.1; SO_4, 8.1; CO_3, 1.7. Too much reliance cannot be placed upon this analysis of an isolated sample; but the figures appear to show that the chloride of sodium in the brine is decreasing and the sulphate of soda, which is a serious impurity, is increasing. The figures are not conclusive, but they indicate the necessity for caution; and, if analyses made in future years show that the deterioration of the brine is continuing, the question of obtaining part of the supply of salt for Upper India from other sources will have to be seriously considered. The possibilities of Sind as a source of supply appear to be worth careful investigation.

The Government has made itself responsible for the supply of salt to Upper India, and is also indirectly responsible for the supply of salt to Bengal; and the present state of affairs cannot be regarded as satisfactory. The formation of a strong Salt Department, possessing a specialised staff, capable of dealing with the technical aspects of the subject, and concerning itself only with questions of production and distribution, appears to be necessary. Experts can watch and prevent the exhaustion or deterioration of existing works, and can apply themselves to the discovery and development of other sources of supply. Any preventive work that may be necessary may be left to the Provincial Excise establishments; but, if an adequate supply of good salt at reasonable prices can be assured, I think myself that the penal provisions of the law may be radically altered, and that the manufacture of inferior salt for domestic consumption need no longer be treated as a criminal offence. If this change in the law be made, the salt revenue, which is one of the most reliable of the financial resources of the Government of India, will no longer be open to attack.

DISCUSSION.

THE CHAIRMAN (Lord Meston), invited discussion on what he described as a lucid and exhaustive paper. He said that on looking at this little-known subject there were a considerable variety of topics which emerged. One topic which would probably interest many of the hearers or readers of the paper was the question of the taxation of salt. This was now becoming somewhat of the nature of a political rather than a fiscal question, but he hoped the taxation of salt would keep its proper place in the financial resources of the country. The handling of that particular tax would be one of the many tests of the financial efficiency of our Indian statesmen. Others who had listened to the paper would be interested in the problem which the question of salt presented to the Indian Government, the problem, namely, of reconciling the habits of the people with the necessary rigour of financial measures. It was a problem familiar to many of them in connexion with forests and other matters. Others might probably think—those, at least, who had visited India as sightseers—of the picturesque aspect of the salt question. Those who had seen certain of the salt mines would agree that there were few things more wonderful in nature than the spectacular resources of those subterranean chambers. Persons of a more serious disposition would probably turn to the way in which a vital industry in India had been managed by British officials from the earliest days of the East India Company to the present moment, the manner in which the early British officials had to feel their way, without expert knowledge or business experience, in the establishment of a great commercial proposition. The author had brought back many memories when he talked about the old Salt Customs hedge. He remembered himself stumbling across this hedge, a long stretch of thorny cactus and other growths running for two thousand miles across India, one of the most extraordinary relics of archaic administration which survived at the present moment. It seemed a long way from the Indian salt hedge to the scientific methods of administration for which Sir Richard Dane had been so largely responsible, and for the further improvement of which he was pressing, so rightly and properly, in the paper that evening. Another aspect of the question was the need for further and more enlightened handling of this little-known subject. That, indeed, was the chief lesson to be drawn from the interesting paper—the necessity for further scientific research into the handling of the great salt monopoly, so as to redeem the moral obligation which had been incurred by the British Government. The British Government had taken upon its shoulders, for good or evil, very largely under the pressure of stern financial reasons, the monopoly of the provision of salt for the people of India, and it had thereby a serious and permanent liability. It had a liability to protect the interests of the legitimate producers of salt in the country, and, what was even more important, it had a very heavy liability with regard to three vital services. The first of these services was the supply to the people of India of the cheap, good and abundant salt, which, as they all knew, was one of the most imperative necessities of life of the simplest and humblest peasant. In the second place, there was the necessity for providing an abundant supply of salt for the cattle of India, an aspect of the question far too often overlooked. In the third place, it was necessary to provide a sufficiency of proper salt as the basis for many of the great commercial industries—industries on which the future of India's prosperity very largely depended. With regard to this last aspect of the question, a gentleman had been present at that meeting only a few moments ago—unfortunately he had had to leave early—who was one of the greatest living authorities, namely, Sir Thomas Holland. Some of his manifold duties had called him elsewhere, and Sir Thomas was unable to initiate the discussion, but he had been good enough to leave the notes of what he had intended to say with Sir Reginald Mant.

SIR REGINALD A. MANT, K.C.I.E., C.S.I., read the contribution from SIR THOMAS H. HOLLAND. Sir Thomas was, he wrote, tempted to comment on many sections of this important paper, with most of which he cordially agreed; but in the time at his disposal his remarks must be limited to the one or two sections in which, with respect, he thought Sir Richard Dane's views merited limited qualification. The subjects with which he (Sir T. Holland) had been personally concerned most intimately were the Sambhar Lake and the Salt Range mines.

Sambhar Lake practically dried up every year, but when it became flooded in each rainy season, the water dissolved out from the silt of the lake-bed below—(1) sodium carbonate in small quantities, (2) sodium sulphate in larger quantities, and (3) sodium chloride, or common salt in still larger proportions. As this solution, or lake brine, was evaporated, the saturation point for the chloride was reached first, and continued evaporation then resulted in the precipitation of clean salt, until the brine reached the saturation point also for the sulphate, when both chloride and sulphate separated together. Thus, to obtain good marketable salt, the process of concentration was stopped when the saturation point for sulphate was being approached. The mother-liquor or bittern, which still contained much salt, as well as the whole of the other sodium compounds, was then drained off and thrown into the lake. In this mother-liquor the ratio of chloride to other sodium compounds was approximately in the ratio of 65 : 35, whilst in the normal dilute lake-brine the ratio of chloride to other sodium compounds was now approximately 86 : 14. With the existing system of manufacture, therefore, the amount of salt obtainable from Sambhar was that surplus which, on removal, would reduce the ratio of chloride to other sodium compounds from 86 : 14, as it was now, to 65 : 35, when manufacture must stop. Obviously, the annual manufacture and removal of about 200,000 tons of salt was gradually lowering the ratio of 86 : 14, and the problem before Government was to estimate the speed at which this degeneration was going on. According to a single analysis made in 1870 the ratio of chloride to other sodium compounds was then 90 : 10; so that a degeneration of just 4 per cent. had followed the removal of over 6 million tons of salt in about 50 years. With variations in the rainfall, slight variations occurred in the composition of the lake-brine; hence the single analysis made in 1870 could not be trusted as accurately representing the state of the lake at that period. If analyses of the average lake-brine had been made regularly after Government took over the lake in 1870, it would have been possible by now to state exactly the rate of degeneration in the composition of the brine; but it was only after he took up the question, nearly 20 years ago, that systematic annual sampling was instituted. Politics permitting, this work would now be continued, and a few years hence it would be possible to estimate precisely the residual resources of Sambhar. The most reliable figures available so far were those due to analyses made by Dr. Christie, of the Geological Survey, between 1907 and 1916. Comparing the average for one five-year period with that of the next, they got a degeneration of 0.7 per cent. of chloride following a removal of just one million tons of salt. If the rate of degeneration were absolutely uniform, and if no change in the method of manufacture occurred, the end of Sambhar as a source of salt would occur when they had removed another 30 million tons, or, at the present rate of output, in another 150 years. Obviously, however, manufacturing troubles would increase as degeneration proceeded, and would become serious long before they reached the limiting ratio of 65 : 35. Even, however, if manufacture stopped when the ratio of 75 : 25 was reached, there would still be 16 million tons of salt obtainable; but to translate the quantity into time, an allowance must be made for the gradually increasing speed of degeneration as the ratio became lowered. The exact number of years was not very important, for, judging by the recent progress of political evolution in India, other changes far more serious—for good or ill—would precede the exhaustion of Sambhar. He would not confuse this obviously rough estimate by discussing the effect of additional salt inflowing annually with the tributary rivers, or of the further contributions from the salt now stored in the deeper layers of silt below the lake-bed. It was sufficient to show that there was no present cause for panic about Sambhar; there was plenty of time to consider other ways of meeting the growing demand for salt. Nevertheless, he agreed with Sir Richard Dane in urging the necessity for studying the situation very seriously; for the responsibility resting on Government was a heavy one.

In 1920 new works were started at Sambhar, and what he hoped was an improved system of manufacture was inaugurated in 1921. Sir Richard Dane placed on him the responsibility for this new system. The responsibility might be his but the credit for the idea and for its execution was due to a Public Works Officer, Mr. Bunting, whose services he (Sir T. Holland) borrowed in 1919. He was not afraid of the responsibility; for the capital spent on the new works had already been nearly recovered by improved returns. They had yet to show, however, that the system was foolproof, and, if the Government resumed its old policy of regarding salt-manufacture as a non-technical occupation, suitable for an underpaid staff, the new system would certainly be exposed to a severe test in the near future. But if worked intelligently, the reforms at Sambhar would secure the following among many obvious advantages:—(1) The newly enclosed area covered a part of the lake into which no river entered, and loss of depth by inflowing silt would thus be negligible. (2) The process of manufacture would be continuous instead of intermittent, thus giving the same outturn on a smaller evaporating area, with consequent saving in the cost of re-making pan beds, as well as a reduction of other expensive forms of maintenance. (3) Manufacture could be carried on at a uniform rate from the end of one rainy season till the commencement of the next, without dispersal of the labour in a dry year when, through famine, the men wanted work, and without the difficulty of assembling them again in a good agricultural year, when they did not want to come. (4) The works being less scattered, the cost of assembly of the salt would be reduced, and a centrally-situated, large, covered store would facilitate the despatch of indents, besides having many other obvious advantages.

Some of those who feared the early failure of Sambhar had regarded the new system of organisation as likely to hasten the end; but uniformity of annual output did not mean more rapid exploitation. Within limits the new system could be expanded or reduced to suit requirements, and could thus be relied on to meet one of the troubles to which Sir Richard Dane had referred, as a consequence of the curtailment of foreign salt supplies during the war, namely, temporary shortage and consequent local profiteering by traders. Hitherto Sambhar had been the victim of a variable monsoon, and its annual output had been alternately very large and embarrassingly deficient, varying from under 4,000 to over 400,000 tons.

The only person who had scored through these vagaries was the trader, whose activities at the expense of the consumer had put into the shade the so-called hardships of the salt tax, which he and others joined in condemning on the false assumption that it was a British innovation, instead of an inherited custom from Moghul times.

He had not referred to the manufacture of sodium sulphate as one of the advantages that should follow the new system of manufacture at Sambhar, because this advantage would not actually follow unless Government employed decently-paid technical officers for an obviously technical job. The sodium sulphate was now returned to the lake with the bitterns, and naturally increased proportionately each year, but its separation and profitable sale as a bye-product would enormously prolong the life of the lake as a source of common salt, by postponing the time when the embarrassing ratio of 75 : 25 will be reached. In the laboratory the separation of sodium sulphate from the Sambhar residual bitterns was perfectly simple, but in practice on a large scale it required abundance of water at the right time during the cold weather, and that had not been possible hitherto. The new system would provide the necessary conditions for translating laboratory practice into operations on a commercial scale, but technical management would be necessary, and it was unwise to place reliance just now on the probability that that desirable improvement would occur.

He did not agree at all with the suggestion that the exploitation of Sambhar, with consequent reduction of its accumulated stocks of salt, was in any way unfair to the States of Jaipur and Jodhpur, from which the lake had been leased by the Government of India. The Government, in exploiting the lake, did not attempt to make profit out of the sale of salt; their revenue was obtained from the tax, which they could charge just the same, whether the States retained the lake and sold the salt themselves in British Indian markets. As to the relatively small amount of salt that might be wanted in the future, for consumption within the two States, Sambhar would continue indefinitely to produce more than both States would ever want. Whatever differences of opinion there might be about the ability of Sambhar to stand the present output of over a million tons in every five years, the lake would never be so exhausted as to be unable to provide the small amounts wanted by the people of Jodhpur and Jaipur, even if it were the only source of salt in Rajputana. Meanwhile, both States were enjoying the financial benefits of rents and royalties paid to them by the Indian Government on a generous scale.

In the Salt Range of the Punjab, Government had been kindly treated by Providence with enormous deposits of rock-salt, exposed for quarrying at the surface, and had been fortunate in finding officers like Messrs. Bolster and Reid, who had made up with common-sense and energy for the disadvantages of a non-technical training. The rock-salt deposit was, however, a "wasting asset," and it would be unwise to rely on the chance of obtaining a continuance of successful management by an underpaid staff, now that mining operations were becoming more complicated.

The strike among the miners in 1920 conveniently served the purpose of forcing his attention to the necessity of reforming the methods of mining. Like many other post-war strikes in India, that of the salt-miners was precipitated by extremist politicians, who, with characteristic incompetence, imagined that it would embarrass the Government. The absence of the men, however, for a few weeks enabled the Government to install machinery, which cost less than the savings in wages, and demonstrated the possibility of obtaining an increased output with a smaller labour force. The only embarrassment that occurred was in trying to find work for the miners when they wanted to come back.

It was obvious that the Salt Range could be developed to any reasonable extent to meet the wants of those areas within reach in which rock-salt was acceptable to the consumer.

Although there was little doubt about the large size of the Punjab deposits, each work required systematic forward development to permit of safe and economic mining operations. The employment of trained mining engineers as managers would ensure that this precaution, hitherto not systematically observed, would be taken in future.

Sir Richard Dane was anxious to remove the rigid restrictions on the local manufacture of earth salt—restrictions that were irksome, not completely effective, hard on the poorest classes, liable to abuse, and tending to divert the Department from their main object of production. The impression that he (Sir T. Holland) obtained seemed to indicate that in many places the cost of preventive measures was not worth the saving in tax, whilst it probably added to the burdens which were gradually killing the saltpetre industry. The restriction of manufacture to a few centres was also adding to the danger of the spread of *reh* in those areas that had an insufficient rainfall, with evaporation that exceeded the run-off. These areas now get their salt from outside, and what entered never left. Every ton of salt that entered areas of this sort added to the soluble salts that appeared gradually as a surface efflorescence, and spread like a disease over otherwise good agricultural land. The ultimate object to be aimed at obviously was a reduction of the salt tax, without necessarily its abolition. Any tax on a scale that increased the temptation to evasion brought the reaction which Adam Smith pointed out to be the inevitable consequence of heavy import duties in England at the end of the XVIIth century. However, that opened another and quite different story.

Mr. William Macnab, C.B.E., asked what [illegible] the chemical composition of the salt ultimately obtained from the brine at Sambhar. It would be interesting to have that information, if the author could give it, in view of the fact that there was so much sulphate of soda and carbonate of soda in the brine.

Sir John O. Miller, K.C.S.I., proposed a very hearty vote of thanks to Sir Richard Dane for the full account he had given of the administration of the Indian Salt Department, and also to the Chairman (Lord Meston) for finding time to preside over the meeting. They were all aware that there was perhaps no Indian official who knew so much about India as Sir Richard Dane, and he thought they had all been surprised, both at the width of his outlook, and at the knowledge of detail which he had shown in dealing with the subject which had occupied his later years in India. They were all quite satisfied that during Sir Richard Dane's management of the Department those responsibilities which the Chairman had enumerated as belonging to the Government of India were very seriously undertaken.

Lieut.-Colonel D'Arcy G. Bannerman, C.I.E., C.V.O., in seconding the motion, said he had had the honour and pleasure once of meeting Sir Richard Dane in the Native State of Rajputana, where he had gone to put a stop to infractions which existed in connexion with the salt agreement made by the Government of India. He knew how successful Sir Richard Dane had been in putting an end to that difficulty, and he also remembered how, directly his business was concluded, he expressed a desire to inspect the jungles of that State, and how successful he was in adding specimens of their fauna to his excellent collection.

The vote of thanks was carried unanimously.

Sir Richard Dane, in reply to the question about the quality of the Sambhar salt, said that all the figures had related simply to the composition of the brine. The matter was rather a difficult one chemically, because while common salt had practically the same solubility in cold water and in hot water, the solubility in the case of other salts depended partly on the temperature of the water. The proportion of chloride of sodium in the Sambhar salt produced was about 95 per cent. As he had said, there was undoubtedly a slight progressive deterioration of the brine, but he did not think that this could have seriously affected the composition of the manufactured salt up to the present. With regard to Sir Thomas Holland's remarks, on the main point he believed that Sir Thomas Holland and himself were in absolute agreement, namely, that the question of salt in India could hardly be allowed to run on in the more or less happy-go-lucky way that it had done for many years. And Sir Thomas Holland would agree with him as to the necessity for specialisation. If there had been a strong specialised Salt Department formed in 1904 the crisis which occurred during the war would have been more satisfactorily met.

NOTES ON BOOKS.

◆

The British Trade Boards System. By Dorothy Sells. London: P. S. King and Co., Ltd.

About four thousand years ago, as the author tells us, there were Government regulations in Babylon defining "..the exact amount to be paid to workers in various occupations," (p. 1); but we may remark that in all periods of which we have detailed record, there has been periodical alternation between free or individual bargaining as regards wages, and legislative control of wages.

Even now with a generally dim vista of historical events and social organisations during six thousand years, we cannot find indubitable and unmixedly clear indications in favour of:— (a.) Completely free bargaining between individual employers and employed; (b.) Combination, and collective bargaining allowed on both sides; (c.) Definite governmental or departmental or plebiscital control of wages, with penalisation of those who disobey. Moreover, we do not know whether a fixed rise in wages is a real and effective increase, or a figment to which social conditions and prices tend to adjust themselves.

It may be well to remind our readers that the present-day Trade Boards are in reality wages boards of a class very extensively experimented with during the development of our country; these present-day Trade Boards are, however, based on recent Australian legislation, as detailed in a report (1907) by the late Mr. Ernest Aves to our Home Office; this report having been issued as a blue book. A good account of this important but much misunderstood incident is to be found on *p.* CVII of the British Supplement to the Bliss Encyclopedia, 1908 Edition, edited by Ed. Page Gaston. It is interesting to note (middle of Col. II), that Mr. Aves expresses doubts as to the desirability of establishing compulsory boards in Great Britain, and as to whether compulsory powers can be effectively exercised.

Thus it will be realised by our readers that the Trade Boards treated of in the work under notice are fundamentally different from the Permanent Industrial Court, as treated of by Sir William Mackenzie in a paper which appeared in the Society's *Journal* of May 11, 1923.

To the student of economics, the manufacturer, and indeed to every employer of labour, the work under notice may be of value as embodying a fund of inner facts as to the working of the present-day Trade Boards, facts gathered by personal observation (*Cf. e.g., p.* 219), or personally communicated details (*pp.*V—VI). In short, we find in this work just the kind of vital detail which is so often lacking in books on economics, and the book inspires the utmost confidence as to the accuracy of the facts. If, however, the facts had been linked together by laborious cross-referencing and a really good index the value of the work would have been much greater.

Two Acts of Parliament and a host of forms, schedules, and papers are more or less summarised in the dictum "The chief business of a Trade Board is to determine what the rates of remuneration shall be in its trade" (*p.* 17), but practical difficulties have arisen and "not infrequently a period of one or two years elapsed before the initial rates became operative" (*p.* 17). The "Grocery and Provisions Trade Board" had a troubled existence of more than two years without getting any rates confirmed," (*p.* 18). Further,"..It has not been an unusual occurrence during the past two years for a Board to propose to vary its rates at the same meeting at which those rates were fixed" (*p.* 18). The apparent insuperable difficulty of defining certain trades and of working on the overlaps, with the incident uncertainty as to which of various trade rates ought to apply runs through the book; but it may be sufficient indication of the difficulty to turn to *p.* 54 where we read of an official "definition" of the Grocery and Provisions Trade, which fills three printed pages.

Much trouble seems to have arisen from the fact that ordinarily a board is free to arrive at its rates by any procedure which it may choose (*p.* 54) and a somewhat remarkable instance of procedure is given on *p.* 219 as having come under the personal observation of the author. "This Board had lived through a most stormy existence, and had worn out two Chairmen in fixing its initial rates." A change was proposed and peace seemed hopeless, but one of the women having spied a box of cigarettes "which had been inadvertently left on the table by the leader of the employer's side," she seized it and distributed the contents, thus "bringing about a settlement without ill feeling." We find, however, no hint as to the equity, desirability or public utility of the settlement.

Apart from the definitely useful function of recording facts, a leading mental note or sense of the book appears to be of interest in many ingeniously set puzzles, and satisfaction when any settlement or conclusion is arrived at, but the real lessons of history seem to be entirely out of mind.

The keynote of the work under notice is post-war influence on wage rates, rent, and economic conditions. As a partial parallel we may refer to the incidents which preceded the oft-mentioned speech of Menenius (Rome about 494 B.C.) on "The belly and the members"; while the incidents which immediately followed this speech seem to indicate or foreshadow much which is embodied in modern Industrial Arbitration Courts and in modern representation. To understand the parallel, reference should be made to Webb's various notes on "Who is the real Landlord" (*e.g.*, *p.* 41 of The Practical Socialist for April, 1887). Also note should be made of the incredibly drastic laws as to debt in Rome at this period. (See *p.* 72 of Student's Rome, Liddell. 1872 Edition, Murray). In Florence, there was (1378-1380) a partial parallel with our present time; rival trade organisations and labour elements being in power, but reaction set in during 1381.

AUSTRALIAN WOODS FOR PULP AND PAPER MANUFACTURE.

During the last three years an investigation of the possibilities afforded by Australian timbers for the production of paper-pulp suitable for the manufacture of newsprint has been carried out by the Institute of Science and Industry of the Commonwealth of Australia, and the results have appeared in a paper entitled "The Manufacture of Pulp and Paper from Australian Woods," by L. R. Benjamin, which has been published in the *Bulletin of the Imperial Institute* No. 25 (1923).

It is estimated that during the next decade the annual demand for newsprint in Australia will reach 100,000 tons. At the present time about 120,000 tons of paper and pulp, of value £5,500,000, are imported each year, of which 70,000 tons consists of newsprint, 12,000 tons of other printing paper, 10,000 tons of wrapping paper, and 6, 000 tons of writing and typing papers, whilst about 5,000-6,000 tons of wood-pulp are imported for use in the Australian paper mills.

There are three paper mills and four board mills in Australia, all of which are situated in Victoria and New South Wales. The total annual output of these mills amounts to about 35,000 tons, comprising about 2,000 tons of fine paper, and 10,000 tons of wrappings, covers, etc., the remainder consisting of paper-board and straw-board.

No newsprint is manufactured in Australia, but there is a local market capable of absorbing the output of two paper mills, producing 100 tons of newsprint a day. The successful establishment of such mills depends on the possibility of obtaining large supplies of raw material from which suitable pulp could be produced at a cost of about £10 per ton.

The general conclusions drawn from these pulping experiments may be summarised as follows. The woods of the eucalyptus and most of the other woods examined contain, on the average, as great a percentage of cellulose as that of poplar, birch, spruce and other standard pulpwoods. In the case of the eucalypt timbers the fibres have a length of a little over 1 mm., and a diameter of one fiftieth to one-sixtieth of the length. The young wood is easily barked and chipped, and is to be preferred to mature timber, although in the case of *E. regnans* the mature wood can be pulped successfully without any variation in the conditions of digestion. Quickly grown wood is easily penetrated by the caustic alkali solution, and is rapidly converted into pulp.

The most suitable woods with regard to yield, ease of pulping, and bleachability of the pulp are the immature eucalypts of South-Eastern Australia, viz. *E. regnans*, *E. delegatensis*, *E. siberiani*, *E. globulus* and *E. obliqua*, although *E. pilularis*, *E. diversicolor* and *E. calophylla* give a larger yield per cord and a larger output per digester than these. The Queensland woods, with two or three unimportamt exceptions, are not suitable for the production of strong, easy-bleaching pulp by the soda process, but some of them, particularly *Aleurites moluccana*, *Tarrietia argyrodendron*, *Grevillia robusta* and *Callitris glauca*, can be used for the manufacture of kraft pulp. Indications were obtained that *Aleurites moluccana* and *Tarrietia argyrodendron* might give better results if treated by the sulphite process. On the whole, it is concluded that the eucalypts offer the most promising field for immediate exploitation.

The laboratory paper-making experiments, using a model Fourdrinier machine and a beater of 3lb. capacity, were carried out with five typical eucalyptus pulps, viz., those of *E. regnans*, *E. pilularis*, *E. maculata*, *E. dalrympliana* and *E. diversicolor*. It was found that these pulps differ from most hardwood soda pulps, as they can be hydrated without difficulty, and when hydrated are capable of forming paper of at least average strength. It is stated that eucalyptus pulps should not be regarded as mere fillers, for giving opacity and bulk, but as "half stuff," possessing considerable strength, and therefore generally useful as paper-making materials. Particulars are given of experiments carried out on a semi-commercial scale at the Barwon Paper Mill of the Australasian Paper and Pulp Co., Ltd., at Geelong. The results of the trials confirmed those obtained in the laboratory, and showed that the woods of the eucalypts are most efficiently pulped by a modification of the soda process, in which the chips are submerged in a weak liquor throughout the period of digestion, external heating being employed in order to avoid further dilution. By adopting this procedure, instead of direct digestion with strong liquor, the yield is increased by as much as 60 per cent. and the strength of the pulp is greatly improved. The eucalypts of Tasmania and Victoria and young karri (*E. diversicolor*) give the highest yield of pulp for equal weights of wood, and are the most easily bleached. The yield of screened pulp for the most important woods was between 45 and 47 per cent. All the woods give a higher yield per cord than either spruce or poplar.

The paper-making experiments showed that mixtures containing 60 to 70 % of eucalypt pulp are capable of furnishing paper of considerably higher bursting and tensile strength than those made almost entirely from spruce sulphite pulp under the same conditions. Moreover, papers made from mixtures containing about 60 per cent. of eucalypt pulp exhibit superior opacity and good finish. In the case of such papers there is less shrinkage during drying than with papers containing a large proportion of sulphite pulp. Well-prepared eucalypt pulps are suitable for many purposes, and specially for the manufacture of the better-grade printing, book, magazine and cartridge papers, and the cheaper grades of writing and typing papers.

The eucalyptus trees proposed as a source of pulp-wood reach a size suitable for cutting in from 8 to 15 years, whereas spruce and other pulp-woods require at least 40 years to grow to this size. Vigorous coppicing of the trees results in the production of dense stands yielding as much as 40 cords per acre in less than ten years of growth. Protection of the forest from fire would be relatively simple and inexpensive. The system of "river driving," which is commonly used for transporting timber from slow growing forests in which the area to be logged is situated farther from the mill each suceeding year, could be replaced in the rapidly growing forests of Australia by a permanent railroad logging system, as the average haul would be small, and the quantity of wood to be transported would be large. It is considered that the cost might be much lower than in many cases of "river driving."

Suitable labour is available in Australia for operating pulping plants, and the cost would not be any greater than in the United States.

In the States in which the greatest reserves of pulp-wood exist large power schemes are in course of development. Cheap hydro-electric energy is available in Tasmania, whilst in Victoria power generated from lignite at Morwell and cheap brown coal itself will be available in a year or two.

Estimates of the cost of production of pulp are given which are based on a small plant with a daily output of 10 tons of air-dry bleached-pulp. Under these conditions, and with fuel at 30s. per ton, wood at 40s. per cord, soda ash at £10 per ton, salt at £4 per ton, lime at 25s. per ton, power at 0.5d. per kiliwatt-hour, and a minimum wage of £4 5s. per week, pulp could be produced at a little less than £13 per ton. Under more favourable conditions and with a larger output, the cost might be reduced to about £10 per ton.

The simultaneous operations of saw-mills and pulp-mills would effect much greater utilisation of the forests than is now possible, and would assist the production of future supplies of mill timber, by providing a market for thinnings from cut-over areas undergoing silvicultural treatment. Moreover, a certain amount of mill waste could be utilised for pulping, in addition to most of the small and some of the defective trees.

It is considered possible that sufficient wood-pulp could be produced in Australia to supply the local paper-making industry with 6,000-10,000 tons per annum, and also to develop an export trade. A paper-mill designed to manufacture printing paper, and using 60-70 per cent. of Australian pulp and some imported pulp, would have the advantages of a supply of cheap pulp, the absence of high freight charges, and the operation of a protective duty on imported paper. A combined pulp and paper mill would offer even better prospects.

The conclusions reached by the investigations described in the *Bulletin of the Imperial Institute* are summarised as follows: (1) An abundance of wood in the form of young regrowth is available for establishing the pulping industry; (2) the wood is easily pulped by a modification of well-known pulping processes, the cost of production being low; (3) the pulp is suitable for a fairly wide range of papers; (4) conditions are favourable for establishing a pulp-mill to supply at least 3,000 tons and possibly 10,000 tons of pulp annually for the local market, and an export trade is also possible; (5) there is little doubt that chemical pulp could be produced in Australia sufficiently cheaply to permit of its use in the manufacture of newsprint.

GENERAL NOTES.

A Tree Planting Machine.—Attention is drawn in the February number of *South African Journal of Industries* to a recent invention designed to facilitate the planting of trees. It is known as the Duivel Tree-Planter, and the principle on which it works is that of taking up the rich nursery soil around the young tree, with the tree in the centre, and planting the whole in the position which the tree is to occupy permanently. The roots are thus left undisturbed, and the tree suffers nothing from its change of position. The removal is accomplished by means of a cylinder which is placed around the tree and pushed down into the soil. By this means a young tree can be removed with a block of soil round its roots nine inches deep and nine inches in diameter. The cylinder is then planted in the designed spot and withdrawn. It is claimed that a young tree can be planted out with the Duivel machine in the hottest sun at any season of the year without suffering any serious setback.

Cattle Breeding in North Manchuria.—North Manchuria has large stocks of cattle, which however, do not reach outside markets, because the industry is but little organised, states the Bureau of Economic Information. The number of horses there and adjoining Mongolia exceeds 3½ million. The number of mules is also very considerable. Large horned cattle are estimated at five million head, whose productivity is excellent, and the meat highly valued for its taste. Pig-rearing is developed in the areas of intensive agriculture, and the total number of pigs reaches 3,200,000 head. The export of bristles, which are the main products of pig-rearing, averages 89-100 tons per annum. The yearly growth of the number of cattle, after providing for natural decreases, epizootics, etc., in the area gravitating to the Chinese Eastern Railway, may be determined as follows: Horses, 140,000; large horned cattle, 350,000; sheep, 1,100,000; pigs, 330,000. Theoretically, almost all might be brought to market, but not more than ten per cent. are. This is explained by absence of regular sales organisation; there are no refrigerators, no sorting arrangements, and neither credit nor capital is found to put the business on a proper standing.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings at 8 o'clock (except where otherwise stated):—

May 14.—F. C. Ingrams, President of the London Fur Trade Association, "Furs and the Fur Trade." Ernest Poland, Vice-President of the London Fur Trade Association, will preside.

May 21.—(Trueman Wood Lecture.) Sir William J. Pope, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, "The Outlook in Chemistry." Sir Herbert Jackson, K.B.E., F.R.S., will preside.

May 28 (at 4.30 p.m.)—Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Indian Section.

Friday afternoon, at 4.30 o'clock:—

Tuesday June 24, at 4.30 o'clock J. C. French, I.C.S. "The Art of the Pāl Empire in Bengal."

Dominions and Colonies Section.

Tuesday, May 27, at 4.30 o'clock.—C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus."

Wednesday, June 4, at 4.30 o'clock.—The Rt. Hon. Sir Frederick Lugard, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member, Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates."

Monday, June 16, at 4.30 o'clock.—C. V. Corless, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada."

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

Monday, May 12 .. British Academy, King's College, Strand, W.C., 5.15 p.m. Dr. E. K. Chambers, "The Disintegration of Shakespeare."

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Prof. E. Naville, "Deuteronomy a Mosaic Book."

Geographical Society, Lowther Lodge, Kensington Gore, S.W., 5 p.m. Captain G. T. McCaw, "The Proposed Adoption of a Standard Figure of the Earth."

Mechanical Engineers, Institution of (Graduates' Section), Storey's Gate, Westminster, S.W., 7 p.m. Engineer-Captain E. C. Smith, "The Makers and Making of our Modern Navy."

East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Mr. F. Wright, "The Sukkur Barrage Project, 1920."

Architectural Association, 34, Bedford Square, W.C., 8 p.m. Mr. Hakon Ahlberg, "Modern Swedish Architecture."

University of London, at University College, Gower Street, W.C., 5 p.m. Prof. G. D. Hicks, "Kant's Theory of Sublimity and Beauty." (Lecture I.)
At King's College, Strand, W.C., 5.30

p.m. Prof. J. A. K. Thomson, "The Art of Herodotus."

At Bedford College, Regent's Park, N.W., 5.15 p.m. Mr. A. Thibaudet, "Albert Sorel." (Lecture I., in French.)

University Extension Lectures, at Gresham College, Basinghall Street, E.C., 6.15 p.m. Mr. A. Compton-Rickett, "Personal Forces in Modern Literature." (Lecture II., Granville Barker.)

Meteorological Society, 49, Cromwell Road, S.W., 5.15 p.m. Prof. V. Bjerknes, "The Formation of Cyclones."

Brewing, Institute of, at the Engineers' Club, 39, Coventry Street, W.C., 7.30 p.m. (1) Mr. E. B. Collier, "Some Experiences in the Erection and Use of Concrete Vessels in the Brewery." (2) Mr. C. A. Finzel, "Note on a Dust-quenching Plant."

Tuesday, May 13 .. Petroleum Technologists, Institution of, at the Royal Society of Arts, John Street, Adelphi, W.C., 5.30 p.m. Mr. R. K. Richardson, "The Geology and Oil-Measures of South-East Persia."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Sir H. Denison, "Australia and the Pacific."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. C. P. Butler, "Photographic Record for Astrophysical Research."

Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment, W.C. (Graduates' Section), 5.30 p.m. Annual General Meeting.

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. J. Barcroft, "Effect of Altitude on Man." (Lecture III.)

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. W. G. Constable, "The History of Decorative Painting in England." (Lecture III.)

At King's College, Strand, W.C., 5.30 p.m. Dr. Drazutin Sabotić, "The Second Reign of Prince Milos (1858—1860)."

At Bedford College, Regent's Park, N.W., 5.15 p.m. Mons. A. Thibaudet, "Albert Sorel." (Lecture II., in French.)

At the Imperial College, South Kensington, S.W., 5.15 p.m. Dr. W. G. Miller, "The Pre-Cambrian — with special reference to Ontario." (Lecture I.)

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m. Annual General Meeting.

Wednesday, May 14 .. Sanitary Engineers, Institution of, Caxton Hall, Westminster, S.W., 7.30 p.m. Dr. E. K. Rideal, "Some Physico-Chemical Factors in Water and Sewage Purification."

University of London, at the School of Economics, Clare Market, W.C., 5.30 p.m. Prof. C. G. Seligman, "The History and Present Position of the British Commonwealth—Racial Problems of the Empire."

Thursday, May 15 .. Royal Society, Burlington House, Piccadilly, W., 4 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. (1) Messrs. I. E. Balaban and F. L. Pyman, "The Bromo-Derivatives of 1-Methylglyoxaline and the Constitution of 'Chloroxalmethylin." (2) Messrs. R. Campbell and W. N. Haworth, "Synthesis of Amygdalin." (3) Messrs. R. G. W. Norrish and E. K. Rideal, "Re-activity and radiation. The Photochemical Union of Hydrogen and Sulphur."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Royal Institution, Albemarle Street, W., 5.15 p.m. Dr. E. V. Appleton, "Atmospheric Interference in Wireless Telegraphy." (Lecture I.)

University of London, University College, Gower Street, W.C., 5.30 p.m. Prof. E. G. Gardner, "Contemporary Italian Novelties."

5.15 p.m. Prof. J. E. G. Montmorency, "The History of Diplomacy."

2.30 p.m. Prof. Sir Flinders Petrie, "Recent Discoveries in Egyptology."

At King's College, Strand, W.C., 5.30 p.m. Mr. Arundell Del Re, "English Influences in Italian Literature during the XVIIIth Century."

5.30 p.m. Prof. T. H. Bryce, "The Development of the Human Embryo up to the appearance of the Primitive Segments. (Lecture I.)

5.30 p.m. Prof. A. J. Toynbee, "Outlines of Byzantine, Near Eastern and Modern Greek (378—1841 A.D.)." (Lecture IV.)

Tropical Medicine and Hygiene, Royal Society of, 11, Chandos Street, Cavendish Square, W., 8.15 p.m. Professor Yorke and Dr. J. W. Scott Macfie, "Observations on Malaria made during the Malaria Treatment of General Paralysis."

Friday, May 16 .. Engineering Inspection, Institution of, at the Royal Society of Arts, John Street, Adelphi, W.C., 8 p.m.

Philological Society, University College, Gower Street, W.C., 8 p.m. Special meeting in honour of the Centenary of the Royal Asiatic Society. Contributions on African Languages.

Medical Officers of Health, 1, Upper Montague Street, W.C., 5 p.m. Prof. J. W. H. Eyre, "Public Health and the Oyster."

Geologists' Association, University College, Gower Street, W.C., 7.30 p.m. Mr. C. C. Fagg, "The Recession of the Chalk Escarpment of the North Downs, and the Origin of the Chalk Valleys."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Discussion on Third Report of the Steam Nozzle Research Committee.

(Yorkshire Section), Municipal Technical College, Hull, 6 p.m. Mr. N. McKenzie, "Belt Conveyors."
